Observations

ON THE

TREATMENT OF HÆMORRHOIDS
BY "CRUSHING."

BY GEORGE POLLOCK, F.R.C.S. ENG.,

SURGEON TO ST. GEORGE'S HOSPITAL.

IT had long been a consideration with me that the method of treating hæmorrhoids by ligature, or by clamp and actual cautery, was usually followed by much more pain than should necessarily be attendant on measures adopted to relieve successfully a patient suffering from piles. Indeed, as all surgeons must have observed, the suffering subsequent to an operation proved sometimes to be so severe, that it made me think some alternative could surely be had recourse to which, while it secured the removal of the hæmorrhoid, would possibly render the subsequent condition comparatively one of little suffering or discomfort.

The ligature, however skilfully and carefully applied, destroys the life of the part by degrees only; the portion in its grip does not die instantaneously, and consequently must naturally be a source of more or less suffering till the death of the part is effected. Its application is often followed by very great pain, never without some, and often accompanied by severe spasm of the sphincter, though of course, as regards pain, much depends on the temperament of the patient. No doubt it may be considered as safe an operation as any in which a ligature and a wound are concerned; and it is absolutely efficacious in the hands of one familiar with its details. But in no instance, as far as my experience extends, can it prove both painful—not unfrequently very painful. Mr. Curling on this point says, the sufferings of the patient after the operation vary a good deal, and though in some they are slight and soon subside, in others "they are severe and prolonged, and accompanied by restlessness and want of sleep."¹

The more recently adopted mode of treatment by clamp, scissors, and actual cautery, though, perhaps, somewhat less painful, is still sufficiently severe to occasion much subsequent suffering, and often for some days. A burnt wound must in most cases be attended by more pain, heat, and discomfort than a clean-cut surface: œdema, retention of urine, spasm of sphincter, bearing-down pain in the rectum, are all more or less the common accompaniments of both these methods of treatment.

It is but right, however, that I should quote shortly the opinions of Mr. Curling on the comparative merits of the two operations. His experience in the treatment of hæmorrhoids, is perhaps not excelled by anyone, while his judgment must be respected by all. Mr. Curling says: "Considerable difference of opinion exists as to which operation, the cautery or the ligature, is the best on the score of freedom from suffering, safety, and speedy recovery without confinement. As respects after-pain there is little to choose if care be taken to incise freely before the ligature is applied, and both operations are equally free from danger. The advocates of the cautery have, it is true, magnified the risks of the ligature. But after a lengthened experience I can state that, with one exception, no fatal case of operation by ligature has occurred either in my public or private practice. In 1868 a man aged fifty-two, upon whom I had operated in the London Hospital for internal piles, and afterwards for fistula, was seized with pyæmia, followed by numerous abscesses, and, after a protracted illness of five months, died. Erysipelas and pyæmia have also followed, though very rarely, the operation by cautery. Some amount of danger must be incurred in every kind of operation, serious results sometimes arising from the slightest causes, and the removal of piles cannot be expected to be exempt from risks which may attend a trifling puncture of the finger." "I continue to

give the preference to the ligature, as more convenient to the surgeon and less alarming to the patient. The operation by cautery is more tedious than by ligature, a matter of little moment when the patient is insensible, and special care is necessary in using the cautery to guard against after-hæmorrhage. In a favourable case the patient is able to leave the couch somewhat sooner, and recovery is, on the whole, somewhat more rapid than after ligature, as the healing of the sores does not commence till after the separation of the ligature, a process occupying four or five days, whereas the eschar or superficial slough produced by the cautery is cast off sooner."²

In considering whether any modified process, likely to be followed by less pain, could be substituted for the methods already alluded to, while at the same time perfect relief could be equally ensured, it occurred to me that any thorough and instantaneous destruction of a part is usually comparatively painless—in the injury itself and in its sequence. A heavy weight falling on a finger or toe, and completely crushing the part, is seldom attended by much pain then or subsequently. Nor under such circumstances does much bleeding occur. A man hit by a bullet in soft tissues is known to have been ignorant of the receipt of the injury until the trickle of blood is observed in the neighbourhood of the wound, and thus it occurred to me that if a pile could be rapidly and effectually destroyed at its base by some instrument which in its action would be analogous to that of crushing the part included in its bite, the vessels of the crushed portion would not be very liable to bleed when the surface of the pile was removed, and the nerves being bruised by this proceeding would be less liable to be followed by pain.

It is now some two or three years since I commenced to put in practice these views. The earlier attempts to crush the base of the pile were occasionally partial failures as regarded the perfect freedom from hæmorrhage. Either from want of proper construction the clamp did not effectually spoil the tissues at the base of the piles; or perhaps from too much of the protruding mass being taken up at a time to enable the clamp to act efficiently, or from some other unexpected cause, some bleeding would occur after the clamp was removed, the pile having been cut away; and this had to be dealt with by ligature. Seldom, however, were more than two or three ligatures necessary, and never was troublesome or recurring hæmorrhage encountered. As successive cases continued to be treated in this manner, any defects of the clamp became manifest, and gradual improvements were made. Still the theory, that crushing the base of the pile should entirely obviate the occurrence of hæmorrhage on the separation of the pile and subsequent removal of the clamp, was not as yet fully realised by the results. Sometimes we had no bleeding; sometimes three or four vessels might be required to be ligatured. But still the one satisfactory result observed in all cases thus treated was that the subsequent pain was quite an insignificant matter. It is not wished to imply in this statement that no one ever complained of pain; but in contrast to the pain attendant on ligature, or that noticed after the application of the hot iron, certainly that which has been observed after this system of rapid crushing, may almost be said to be a *minus* quantity. One patient complained of pain for about three hours. In all cases patients have expressed themselves free from severe pain, and many have hardly complained of any after an hour or two. One, who had some years previously undergone an operation by ligature, expressed his extreme gratification at the almost entire absence of even discomfort after the first effects of the ether had gone off.

The application of the heated iron to the surface of a fresh cut wound must not only necessarily make it a very painful one, but burning the surface necessarily converts it into a more extensive slough, which has to be thrown off before healing commences. The slough to be shed after the application of the clamp now used by me, is very thin and quite superficial, and is soon cleared away. The œdema following this method of relief is but little compared to that which is often observed to follow the application of the ligature or the cautery. Having now tested all these methods of treatment not a few times, I cannot but express my very strong conviction that, compared with the results of ligature or cautery, the pain and subsequent discomfort after crushing are really trifling. But apart from the question of pain or bleeding, the operation itself is rendered very simple

¹ Curling on Diseases of Rectum, p. 57. Fourth edition.
No. 2966.

by the use of this kind of clamp, and in that point alone we venture to think it will be considered an improvement by those who care to test it for the removal of hæmorrhoids.

Messrs. Wright and Co., of New Bond-street, and Messrs. Weiss and Co., of the Strand, have made several clamps for me, each being some improvement on the last; but the most perfect, and that now used, was made by Messrs. Wright, at the suggestion and under the superintendence of Mr. Benham, at present a pupil at St. George's Hospital. His mechanical skill has not only been the means of effecting improvements in this and other instruments, but gives promise of great service in many respects, as a thoughtful and successful inventor. His own description of the clamp is appended, and will be readily understood with the aid of the illustrations given herewith.

The process of the application of the clamp remains to be described. The patient suffering from hæmorrhoids, being prepared for the operation in the usual manner, is to be placed under the influence of ether. He is then turned on his left side; the right leg to be well flexed and fixed with a strap, which is to be carried under the knee and round the neck. The pile to be removed is to be drawn well down by pronged hook, or forceps. The clamp is then to be applied to the base of the pile, and at once tightly and firmly closed by the action of the screw at the end of the handles. The portion of pile which protrudes *inside* the lips of the clamp is then to be removed by a pair of curved scissors. The clamp may afterwards be retained, still grasping the stump of the pile for any time the operator may consider desirable. Our usual custom is to retain it from half a minute to a minute. If the pile be large and thick it may be well to retain it for a rather longer period. This process is, of course, to be repeated according to the number of masses to be got rid of.

Since this last clamp has been used, one or two little vessels have bled after the base of the pile was relieved from the grip of the instrument; nothing more, however, than would have ceased without interference in a short time. But to keep the patient clean, and to avoid giving any cause for uneasiness, a ligature had better always be applied at once to any suspicious bleeding point rather than run the risk of its continuance. A ligature applied under such conditions is known not to cause any subsequent pain, and in its effects is not to be compared for a moment to the pain occasioned by a ligature placed through or round a pile. In fact, pain, as already mentioned, is not often complained of when the patient has recovered from the effects of ether, even though two or three ligatures may have been applied to as many

bleeding points. It is better, however, to avoid all risk of bleeding by securing any continuous oozing point. Every surgeon familiar with operations connected with the lower bowel is aware of the necessity of proper respect for any trifling point of bleeding, and it is far better to secure it while the patient is quiet and under the influence of ether, than to run the risk of having to attend to it later. Still it will generally be found that very little is required in this respect after the pile has been thoroughly crushed by the forceps described. In the various cases as yet so operated on, no such accident has followed; but on the principle that it is always better in surgery to avoid a difficulty than have to overcome one, we recommend the securing of any suspicious bleeding point than to run the risk of its continuing to bleed, or trusting to the chapter of accidental arrest.

Having now tested this operation in many cases of hæmorrhoids, and feeling satisfied that, as regards pain, it is preferable to treatment by ligature or cautery; that as regards its efficiency, it is equal to either; and as regards the operation, it is essentially simple and satisfactory, it is but right that it should be brought more generally to the notice of the profession than can be done by its performance alone in the operating theatre of St. George's Hospital, or in the smaller sphere of private practice. The experience of not a few years in hospital work will perhaps be some justification for my venturing to recommend an operation which to my mind presents a simplicity that places it within the reach of any practitioner, and at the same time renders it one of far less suffering to the often too sensitive patient who may be the subject of hæmorrhoids. I need only add, that the subsequent dressing employed after the operation is completed, is as simple as the operation itself. "Tarred cotton," as prepared by Messrs. Bell & Co., of Oxford-street, or that prepared with salicylic acid, with warm bathing, is the only local application employed until the sores are healed.

The following are Mr. Benham's remarks on the construction and mechanical advantages of the clamp:—"1. It is so constructed as to form a multiplying double lever of the first kind, the fulcrum being formed by the joint, the resistance by the tissues acted on, and the power by the thumb-screw at the other extremity of the clamp. 2. The parallelism of the jaws is governed by the joint; for the former being situated in close proximity to the latter, any appreciable lateral spring is prevented, especially as the substance of metal forming this part of the structure is of great strength—hence all the strain is thrown upon the joint—the construction of which is as follows: The opposing surfaces are of large size, are accurately fitted together, and are connected by a lock-nut, so that it is almost impossible for the jaws to spring from their parallelism in the slightest degree. 3. The opposing surfaces of the jaws are *not horizontal*, but are inclined at an angle of 45° , which has the following advantages—(a) Besides a jamming, there is a grinding movement; (b) The power in overcoming the resisting forces is represented as two equal forces, acted upon by their resultant at an angle of 45° ; (c) By this inclination it pulls the surface of the bowel close to the jaws—this being an immense advantage, especially if the operator be unable to draw the tissues, to be acted upon, close to the opposing jaws. 4. That portion of the clamp which forms the handles is so constructed as to admit of a slight spring or elasticity, when the screw is firmly applied, has the following advantage—namely, if, when the clamp is first applied to the tissues, they do not yield, they may be made to do so by the gradual crushing power which is brought to bear by the elastic recoil of the handles.

"The following is a rough estimate of the mechanical advantages gained, the calculation being somewhat under than above the estimation:—1. The extremity of the handles being four times further from the fulcrum than the jaws, an advantage is gained of four to one. 2. The screw which is attached to the extremity of the handles having a pitch of one-eighth to the inch, and the radius of the thumb-screw being one inch, there is a gain of eight to one, and if the screw be applied with a force of only 20 lb., we have $8 \times 20 \text{ lb.} = 160 \text{ lb.}$ "

It may hereafter prove advantageous to use this powerful clamp in various other operations, in which the removal of parts may be desirable without the intervention of the knife; such, for instance, as a portion of the tongue, pendulous tumours, &c.; but, as yet, I have entirely confined its use to the treatment of hæmorrhoids.

BRIEF NOTES OF A VOYAGE TO BRAZIL.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,

HONORARY CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL, AND
CONSULTING PHYSICIAN TO THE HOSPITAL FOR DISEASES OF
THE CHEST, VICTORIA PARK.

HAVING recently paid a visit to Brazil, I think a short account of my voyage may not be without interest.

Leaving Southampton by one of the mail steamers in the afternoon, the first stage of the voyage, to Lisbon, is generally accomplished in about four days; but in our case, in consequence of the vessel having to call at Cherbourg, and of our being detained outside the bar of Lisbon by fog and a heavy swell, the voyage occupied five days. Thence to St. Vincent, Cape Verde Islands, is about six days' steaming, and from St. Vincent to Pernambuco occupies about the same length of time, and the voyage from Pernambuco to Rio is accomplished in about five to six days; so that the whole time from Southampton to Rio is about twenty-two days, though with the powerful steamers of the Royal Mail Company the time could probably be easily reduced by one or two days. The distance measured on the chart is 5170 nautical miles, or probably, taking the actual course of the ship, 6200 nautical miles.

In going out we went through the Canary Islands, passing within about eight miles of Santa Cruz, the capital of Teneriffe. I was disappointed in not getting a good view of the Peak; but we passed it at night, and though it was bright moonlight, the island was covered with a dense mass of cloud.

St. Vincent is a very remarkable island. It consists of ranges of mountains which, though picturesque in their outlines, being entirely devoid of verdure, are not pleasing. It, in fact, resembles an immense cinder, and seems to be composed of masses of lava with intervening layers of volcanic ash. The bird rock which arises abruptly from the sea to a considerable height at the entrance of the harbour of Porto Grande shows this structure very conspicuously. The island of Santo Antonio, which lies to the north-west of Porto Grande, is a great contrast to the island of St. Vincent, having some appearance of luxuriance, and producing vegetables and fruit in abundance. This difference is probably partly due to the soil being less porous than that of St. Vincent, and partly to its position exposing it more directly to the north-east trade wind, and so giving it a better supply of moisture, either in the form of rain or dew. On both the occasions of my being at St. Vincent on the voyage out and home, the island of St. Antonio was enveloped in a thick mist, though the sky at St. Vincent was quite clear. It is the opposite or north-east side of St. Antonio which is the most productive, and that side is the most directly exposed to the trade wind.

From St. Vincent, in lat. $16^{\circ} 34' N.$ and long. $25^{\circ} 1' W.$, to Pernambuco, in $8^{\circ} 3' S.$ lat. and $34^{\circ} 49' W.$ long., is 1614 nautical miles, and the time occupied in the voyage six days. The first land which is usually made on approaching South America is the coast about the city of Olinda. This city is beautifully situated on a high and well-wooded point of land projecting into the sea—indeed, it is said to owe its name to the beauty of the site. Immediately after passing Olinda Pernambuco comes into sight; here the larger vessels anchor in an open roadstead two or three miles from the land, but smaller vessels enter the harbour. This is formed by a reef of rocks which rises abruptly from a depth of three and a half to four and five fathoms. Inside the harbour is shallower, and there are two entrances into it, one to the west of the lighthouse, and between it and an old Dutch fort, which can only be used by boats and small vessels, the other with deeper water further to the east. The reef is spoken of by Mr. Darwin as "perhaps the most artificial-looking natural structure to be seen in any part of the world. He describes it as running in a perfectly straight line for several miles, parallel to and a short distance from the coast. Its surface is level and smooth; at high-water it is covered, but at low-water the summit is left dry, and it might then be mistaken for a breakwater erected by Cyclopean workmen. On this coast the currents of the sea tend to throw up in front of the land long spits and bars of

loose sand. In former times a long spit of this kind seems to have become consolidated by the percolation of calcareous matter, and afterwards to have been gradually upheaved, the outer and lower portions during this process having been worn away by the action of the sea, and the solid nucleus left as we now see it. Although night and day the waves of the open Atlantic are driven against the outside of this wall of stone, yet the oldest pilots know of no tradition of any change in its appearance. This durability is due to a tough layer, a few inches thick, of calcareous matter wholly formed by the successive growth and death of the small shells of serpulæ, together with some few barnacles and nulliporæ, which are hard, very simply organised sea-plants."

In front of Pernambuco the reef has been built upon so as to form a pier; and ordinarily the water in the harbour is perfectly quiet and smooth, but occasionally the swell rolls entirely over the reef, producing rough water inside. The reef has a width of from thirty to sixty yards, and it is composed of an obscurely stratified hard sandstone.

Pernambuco consists of three towns—Recif, Santo Antonio, and Boavista. The first is built at the side of the harbour, and contains only warehouses, offices, and establishments connected with the shipping. In the other towns, which are separated from Recif by the harbour and a small river, the streets are wider than in most Brazilian towns, and the shops are good and apparently well supplied with articles of European manufacture. Altogether, Pernambuco is one of the largest and best towns in Brazil, and it is the seat of a large export trade in sugar and cotton, which are brought down from the interior by railway.

From the complete exposure of the coast off Pernambuco to the swell of the South Atlantic driven by the south-east trade wind, the landing from the ships in the roadstead is often difficult; but as the native boats are large and powerful and the boatmen very expert, accidents seldom if ever occur; but the landing is sufficiently difficult to try the nerves of inexperienced voyagers. The fishermen use a kind of raft or catamaran, called "jangada," with which they go out to sea many miles.

The next port, which is reached after about thirty-six hours' steaming, is Bahia or San Salvador. This, as the name indicates, is situated upon a large bay, partly protected towards the south east by the island of Itaparica. The town is built around a smaller bay within the larger one. It was formerly the capital of Brazil and is still a large and important place, and has the advantage of being much more healthy than Rio. The city consists of an upper and lower town. The latter is built upon the shore of the bay, and is chiefly occupied by establishments connected with the shipping. The upper town is situated on a ridge, rising 500 or 600 feet from the sea. This contains the private residences and many churches. Formerly it was very difficult of access from the shore, and visitors used to be carried up the steep incline by negroes in a kind of palanquin or open sedan chair; now, however, there is an elevator, by which persons are rapidly transferred from the lower to the upper level. The upper town consists chiefly of one long, narrow, irregular street, running on the ridge parallel to the bay, and as the ground inclines rapidly on each side there are at intervals beautiful views into the country and to the bay. In the suburbs the better class of houses stand separately in small gardens. The Passeo Publico, about a mile from the centre of the town, is situated on a high point, overlooking the bay, and is rich in tropical vegetation. Here for the first time I saw the Royal or Imperial Palm, the *Oreodoxa oleracea*, the Pandanus or screw pine, and various other tropical trees. The Fan palm is common in the gardens at Bahia, and mango trees are very common. A sail of about three days from Bahia brings the ship to the entrance of the harbour of Rio, passing during the voyage the rocks and islets of the Abrolhos and Cape Frio. As we approached Cape Frio there was a very marked change in the climate, the heat being sensibly diminished, from the existence of a cool current which flows up the east side of South America. After arriving off the north-east coast of South America the temperature of the seawater was regularly $84^{\circ} F.$, while off Cape Frio it was only 80° to 82° , and to this greater coolness of the sea the comparative freshness of the atmosphere off Cape Frio is doubtless due.

The city of Rio, as is well known, is placed in a large and almost landlocked bay, surrounded by mountains of very picturesque, almost grotesque, forms, attaining very considerable elevation, and clothed in their lower slopes with most luxuriant vegetation. The entrance to the bay is

between two forts situated on rocky elevations—St. Julian and Santa Cruz. It is very narrow, scarcely a mile in width, though within the entrance the bay expands, and it runs a considerable distance inland, and is broken into numerous smaller bays with intervening promontories, and studded with numerous rocky islands. On the left side of the entrance are situated the Sugar-loaf and the Corcovado mountains, respectively attaining heights of 1270 feet and 2272 feet. More towards the sea is the Gavia, a very curiously-shaped hill, 2575 feet high, and further inland are the peaks of Tijuca, the highest attaining a height of 3316 feet. On the right hand side of the bay are situated the Organ mountains, picturesque peaks of still greater elevation.

The city of Rio is situated on a peninsula jutting out into the bay on the south-western side, and not far from the entrance. The site is low and level, and does not afford any natural facilities for drainage, and the attempts which have been made to improve it do not appear to have been very successful. The outlet of the drains is into a small bay within the larger one, through which there can be very little current, instead of being carried into the open sea. The entrance to the bay is too narrow to admit of a free sweep of tide, and the mountains which surround the town, though they add greatly to the beauty of the site, must interfere with the free perfilation of air. The supply of water is also at present very defective. The streets are narrow and the houses built very closely together, and closed at the back. I have also reason to believe that very many of them lack the proper arrangements for cleanliness and comfort. It is therefore no cause for surprise that the town is very unhealthy, and that yellow fever prevails, more or less, during the hot season every year. Arrangements are being carried out for an increased supply of good water to the town, and it is to be hoped that this will lead to an improvement in its sanitary condition. Though, however, Rio itself is so unhealthy, there are at short distances from the city localities that are in every respect unexceptionable. The Europeans generally reside during the unhealthy season at hotels or country houses on the hills a few miles out of town; and of these Tijuca, about eight miles from Rio and 800 feet above the sea, is one of the most popular places of residence. I myself lived while there at Anderye Grande, at an hotel on the side of a mountain about four miles from Rio, and 400 feet above the bay. Here the mornings and evenings were delightfully cool, and the hotel commanded a beautiful view down a forest-clad valley, with Rio and the Organ mountains in the distance; and I have every reason to believe that the place was quite healthy.

From the peculiar form of the mountains around Rio, the impression would be conveyed that they owe their origin to volcanic action, but this is not the case. They consist of primitive rocks—quartz, granite, gneiss, sienite, &c. It is the opinion of Agassiz that the country has been subjected to the action of glaciers, and this opinion he founds upon the existence of travelled boulders in situations which they could scarcely occupy unless conveyed thither by ice.

I should have wished to obtain some information in reference to the climate of Rio and Brazil, but in this I have very imperfectly succeeded. From the great extent of the country, which ranged from 4° of North latitude to 33° 40' South latitude, a distance of about 2600 miles, it will readily be understood that the temperature must vary greatly in different parts. At Para, in the north, it has a mean of 81° F., and a range of from 76° at night to 85° in the day; at Ceara the range is from 83° to 75°; at Pernambuco from 77° to 86°; and at Bahia from 75° to 85°. The temperature of Rio is somewhat less, while at Rio Grande do Sul, in the south, it is 44° in the winter and 85° in the summer. At the River Plate the temperature is said to have an average of 65°. Of the rainfall I am unable to give any specific statement, but from the number of running streams and the extreme luxuriance of the vegetation, it is evident that there must be a large fall of rain.

(To be concluded.)

On the 16th ult., a large number of the inhabitants of Ottery St. Mary and its vicinity, assembled in the Town Hall for the purpose of asking Dr. Whitby to accept a proof of the estimation in which he is held by those among whom he has practised for nearly twenty-eight years. The testimonial consisted of a gold watch, value £25, and a purse of 150 guineas.

A THIRD SERIES OF CASES OF STONE IN THE BLADDER TREATED BY LITHOTRITY AND RAPID EVACUATION OF THE FRAGMENTS (BIGELOW'S METHOD).

BY WALTER J. COULSON, F.R.C.S. ENG.

CASE 1.—Edward S—, aged fifty-nine, living in Yorkshire, came under observation Feb. 16th, 1880. He complained of the ordinary symptoms of stone in the bladder, and had suffered from them for about three years; had only once noticed a little blood in the urine. Not subject to gout or rheumatism; no family history of stone; has not suffered from pain in the back or loins. Frequency of micturition is now the most prominent symptom; he passes urine nearly every quarter of an hour during the day. The secretion is of a pale-sherry colour, has an alkaline reaction, sp. gr. 1018, and deposits mucus and phosphates. The patient's general health is good. A small calculus is readily detected on sounding.

On Feb. 19th, the patient being under the influence of ether, and the narrow meatus urethræ having been incised with a bistourie cachée, I crushed the stone about twenty times, using the fenestrated lithotrite. Bigelow's apparatus with the curved evacuating tube was then applied, and the detritus removed. Owing to the rigidity of the enlarged prostate, some little difficulty was experienced in the introduction of the tube. In order to overcome this, I had recourse to a method which I can confidently recommend for adoption in all similar cases. Having passed the tube down the urethra as far as it would go, I attached the bottle and gently injected a little water. The fluid, finding its way into the bladder, dilated the urethra, and the tube readily followed. On completion of the operation, the bladder was examined with the non-fenestrated instrument, and no fragments were detected. The operation lasted twenty-four minutes, and was well borne by the patient. The weight of the fragments removed was seventy grains.

Two hours after the operation the patient passed urine freely; there was no trace of blood, and only slight pain in the urethra. At 10.15 P.M., temperature 99°, pulse 72, the patient comfortable in every way. On the following day the condition was perfectly satisfactory; no pain, no débris in urine, which was passed freely. The patient was allowed to sit up on the 21st, and on the 23rd (the fourth day after the operation) he was free from all symptoms of calculus.

CASE 2.—Joseph L—, aged seventy-one, came under observation March 2nd, 1880, suffering intensely from symptoms of disease of the urinary organs. He stated that more than twenty-five years ago he began to notice brick-red sediment in his urine, and occasionally larger fragments. There was at first not much local irritation, but a few years later micturition became very frequent, and he suffered from pain at the end of the penis, and smarting along the urethra. About sixteen years ago he appears to have had an attack of acute cystitis, which was at the time attributed to "catching cold." The symptoms were very severe, and the urine subsequently became very offensive, and often contained a great deal of blood. The intensity of the symptoms afterwards abated, but about four months ago they again became very severe. When first seen the patient was passing urine every half hour, and suffering intense pain, which was greatly aggravated by jolting. The urine was very offensive, strongly ammoniacal, with a copious white gelatinous precipitate consisting of pus cells, phosphates, and much vesical epithelium; sp. gr. 1012. The patient had a careworn look indicative of severe suffering, and had lost flesh rapidly during the last few months. No history of gout or rheumatism, and no apparent hereditary tendency to those affections or to calculus; the patient had always lived freely. A large calculus detected on examination.

On March 4th, ether having been administered, I crushed the stone nearly fifty times, using a fenestrated lithotrite. The parts were much relaxed, and on that account there was some difficulty in introducing the instrument. After using the curved tube and thoroughly washing out the bladder, the lithotrite was reintroduced and the fragments repeatedly

crushed. The tube was again used and a quantity of débris removed, but there were still many fragments left in the bladder. The patient was under the influence of ether for forty-seven minutes, and upon the whole bore the operation well, but owing to his condition it was not thought expedient to prolong the sitting. The weight of the fragments removed was 210 grains. After the operation a warm poultice was applied to the supra-pubic region. On the evening of the day, temperature 102°, pulse 100. Some pain in passing water; urine clear, without offensive odour; no débris.

On the following day the patient was comparatively comfortable; had had a good night, and there had been no rigor. The pain in passing urine was somewhat less, and the calls to do so less frequent. Ordered a suppository containing half a grain of morphia. In the evening a quantity of grit was passed. Forty-five ounces of urine were voided during the twenty-four hours succeeding the operation. On the second and third days the condition of the patient was satisfactory. The urine was abundant and free from offensive odour, and contained several fragments. On the fourth day after the sitting the urine again became offensive, and the muco-purulent deposit increased in quantity.

On the 10th of March the operation was repeated, the patient being, as before, under ether. I made eleven distinct crushings, after having with some difficulty secured what from its size appeared to be a second calculus. The operation lasted about half an hour. In consequence of the patient's weak condition it was not thought advisable to persevere with the operation, during which, however, sixty-five grains of débris were removed. In the evening the patient's condition was comparatively satisfactory; there were no rigors, and the urine was free from blood. Pulse 100, temperature 103°. Some pain above pubes and in passing urine. The morphia suppository was repeated. On the following day the pulse and temperature were normal. Forty-five ounces of urine were passed in the twenty-four hours succeeding the operation. During the next three days the patient's condition still further improved. The urine, however, contained a great quantity of pus and vesical epithelium, and had a slightly ammoniacal odour.

On March 15th the patient was submitted to a third operation. The fenestrated lithotrite was first used, and was followed by Bigelow's apparatus. The non-fenestrated lithotrite was subsequently introduced, and several small fragments were crushed in succession. The bladder was then washed out as before, and débris weighing sixty grains was removed. The operation lasted thirty-five minutes. The patient, however, appeared much weaker than previously, and it was deemed unsafe to prolong the administration of ether. In the evening the patient expressed himself as feeling more comfortable. Temperature 100°; pulse 96; tongue moist; no thirst.

On the following day the temperature and pulse were normal; urine free from blood, but containing muco-purulent matter. No débris passed. On the second day after this sitting the patient's condition appeared to be so far improved that he was allowed to take a short drive. On March 18th he was reported to be still better, the urine was clearer, and the pain less troublesome. Ordered a mixture consisting of the decoctions of uva ursi and tritium repens. The improvement continued until the 21st of the month, when he began to complain of great pain in the bowels and in passing urine, and of thirst and loss of appetite. The tongue became dry, and the abdomen tympanitic. On the following day all the symptoms were aggravated, the meteorism increased, vomiting and hiccough took place, and the urine dribbled away involuntarily. The patient died at 2 A.M. on March 23rd.

Post-mortem examination sixty-three hours after death.—Body fairly nourished; signs of decomposition evident. Heart and lungs healthy. In abdomen evidences both of recent and old-standing peritonitis. Bladder adherent to neighbouring organs, its walls thickened and pulpy, breaking down on slight pressure; all its coats in an advanced stage of degeneration; its cavity filled with pus; a single tiny calculus, of the size and shape of a pea, was found imbedded in the pulpy mucous membrane of the posterior wall. No fragments discoverable. Ureters much dilated, and filled with pus. Numerous abscesses in both kidneys.

CASE 3.—Martin O—, aged fifty-four, came under observation April 6th, 1880, complaining of the ordinary symptoms of calculus in the bladder. He stated that during the last five years he had passed several small calculi, and

that, for some time before these began to appear his urine was often high-coloured, and deposited a pinkish sediment and particles of gravel. During the last nine months the pain and frequency of micturition had become much more troublesome, and his urine had several times contained blood. The pain apparently was not increased by movement; it was most marked at the end of the penis. The patient had always lived freely. There was no family history of gout or rheumatism. His urine, when examined, was found to be of a light sherry colour, with an acid reaction and a deposit of urates, uric acid, and vesical epithelium; sp. gr. 1015. A calculus detected on sounding.

On April 7th, the patient being under the influence of ether, I passed a fenestrated lithotrite, and found that the bladder contained several calculi. These were crushed eighteen times in succession, and Bigelow's straight tube subsequently introduced. This, however, became blocked up by a collection of fragments, and had to be removed, and the washing out was completed with the aid of a curved tube. On withdrawal, the bladder was examined with a non-fenestrated lithotrite and a sound in succession, but no fragment could be detected. The operation lasted thirty minutes, and was well borne by the patient. The weight of the fragments removed was one hundred grains.

The operation afforded complete relief to all the symptoms, and was not followed by any local or constitutional disturbance. The urine showed no traces of calculus, and on the third day after the operation the patient expressed himself as freed from all his previous symptoms.

Remarks.—The second of these cases presents, in all its features, a marked contrast to the other two. The duration of the symptoms, their severity, and the obviously profound constitutional disturbance conspired to render the patient a very unpromising subject for any operative procedure. The first and second sittings were, however, followed by far less local and constitutional irritation than might have been expected; and had the patient been able to sustain a more prolonged administration of the anæsthetic, it is probable that the bladder would have been freed from all fragments at the second sitting. The third operation was not immediately followed by any symptoms indicative of the approaching fatal termination. These did not appear until the sixth day, the patient's condition in the interval being so far satisfactory that he was allowed to take a short drive. The state of the urinary organs, as revealed by the autopsy, clearly demonstrated the impossibility of a successful result, and that temporary relief of the patient's sufferings was all that could have been attained. For many years the symptoms had been indicative of the presence of a calculus in the bladder, and the marked pathological changes were exactly those usually found in cases of long standing where proper surgical aid has not been afforded. With regard to the operation in this case, the difficulty in passing the tube, due to the extremely flaccid condition of the urethra, is a point worthy of notice. Instead of gliding over the surface, the tube was felt to be continuously resisted in its passage by a fold of the lining membrane and wall of the urethra. In the first case, the difficulty in introducing the tube was due to the enlargement of the prostate and consequent rigidity of the prostatic portion of the urethra. It is most important in all such cases to avoid using force. I have reason to believe that in one if not two recent instances a fatal result has followed unsuccessful attempts to introduce the full-sized evacuating-tube. It is obvious that if by a protracted operation we thoroughly break up a calculus and then fail to relieve the bladder of the numerous sharp fragments we have made, we expose the patient to serious risk, and his prospects will in all probability be further impaired by repeated but unsuccessful attempts at introducing the evacuating-tube. The plan of injecting a little fluid, as described in the notes of the first case, will be found to answer equally well, whether the difficulty be due to the above-mentioned causes, or to another sometimes met with—viz., the adhesion to the urethral mucous membrane of pulverulent débris. Obstruction from this cause was experienced in one of the cases recorded in THE LANCET, Jan. 31st, of this year. While taking care not to injure the urethra by the introduction of the tube, it is, of course, equally necessary to avoid pinching and lacerating the mucous membrane of the bladder when using the lithotrite. This accident is likely to occur if the lithotrite be pressed against the base of the bladder so as to produce a hollow into which the stone may fall, and it may be guarded against by adopting Civiale's method, in which contact with the vesical walls is as far as

possible avoided. In none of my cases was there any trace of blood in the urine passed after the operation. The results in the first and third cases of the series now reported must be regarded as eminently satisfactory, and well illustrate the advantages of Bigelow's method. No local or general disturbance was set up by the operation, while the relief afforded was immediate and complete.

Harley-street, W.

ON GLYCERINE IN FLATULENCE, ACIDITY, AND PYROSIS.

By SYDNEY RINGER, M.D.,

AND

WILLIAM MURRELL, M.D.

AN old gentleman, who for many years suffered from distressing acidity, read in a daily paper that glycerine added to milk prevents its turning sour, and he reasoned thus: "If glycerine prevents milk turning sour, why should it not prevent me turning sour?" and he resolved to try the efficacy of glycerine for his acidity. The success of his experiment was complete, and whenever tormented by his old malady he cures himself by a recourse to glycerine. Indeed, he can now take articles of food from which he was previously compelled to abstain, provided always that he takes a drachm of glycerine immediately before, with, or directly after, his food. He recommended this treatment to many of his friends—sufferers like himself—and one of these mentioned the above circumstances to us.

We have since largely employed glycerine, and find it not only very useful in acidity, but also in flatulence and pyrosis, and that it sometimes relieves pain. We meet with cases where flatulence, or acidity, or pyrosis is the only symptom, but more frequently these symptoms are combined. Some patients rift up huge quantities of wind without any other symptoms than depression of spirits; in others we get flatulence and acidity, one or other predominating; and we meet with others who suffer from acidity, flatulence, and also pyrosis. In all these various forms we find glycerine useful, and in the great majority of cases very useful. We do not mean to say that in all cases it is superior to other remedies for these complaints; indeed, in several instances it has only partially succeeded, where other remedies at once cured. On the other hand, in some cases glycerine speedily and completely succeeded, where the commonly used remedies for acidity and flatulence completely failed. We do not pretend to estimate its relative value to other remedies; we are only anxious to draw attention to its virtues.

Gas is in some instances formed in the stomach, in others in the large intestine, in some patients in both. Our observations were made on stomach flatulence, and as glycerine is so readily absorbed we should hardly expect that it would influence the formation of wind in the colon, except given in large doses, and when it acts as a slight laxative, and so expels the putrefying mass which forms the wind.

In some cases it removes pain and vomiting, probably, like charcoal, by preventing the formation of acid acids, which irritate delicate and irritable stomachs.

We suggest that it acts by retarding or preventing some forms of fermentation and of putrefaction. J. Mekulics¹ shows that glycerine prevents putrefaction of nitrogenous substances, as of blood diluted with water, which speedily decomposes at the ordinary temperature of the air. Two per cent. of glycerine retarded decomposition for twenty-four hours; 10 per cent. for five days. If the fluid were placed in the hatching oven, then 2 per cent. retarded decomposition for several hours, 10 per cent. for forty-eight hours, and 20 per cent. altogether prevented putrefaction. He also proves that glycerine destroys bacteria and prevents the formation of septic poison, though it will dissolve and preserve the septic poison itself.

Dr. E. Murk² finds that 2 to 3 per cent. will delay lactic fermentation in milk from eighteen to twenty-four hours.

Burnham Wilmot, 1860, says glycerine preserves meat so that after several months' immersion the meat is sweet and

can be eaten; and Demarquay proves that both animal and vegetable substances may be kept for six weeks to two months by glycerine.

Glycerine, however, does not prevent the digestive action of pepsin and hydrochloric acid; hence, whilst it prevents the formation of wind and acidity, probably by checking fermentation, it in no way hinders digestion. We administer a drachm to two drachms either before, with, or immediately after food. It may be given in water, coffee, tea, or lemon and soda water. In tea and coffee it may replace sugar, a substance which greatly favours flatulence, as, indeed, does tea in many cases. In some instances a cure does not occur till the lapse of ten days or a fortnight.

A CASE OF LITHO-NEPHROTOMY.

By E. HOOPER MAY, F.R.C.S.,

SURGEON TO THE TRAINING HOSPITAL, TOTTENHAM.

MRS. B—, aged fifty-five, a pale but fairly healthy-looking woman, complained, in July, 1879, that her urine was thick and very offensive, and that for some time past, though able to perform her duties, she had not been feeling well. The urine was found to contain pus. Upon examination on the 17th September, a large tumour was found on the right side of the abdomen, occupying the space between the last rib and the crest of the ilium, and bulging anteriorly and into the loin. This was believed to be a suppurating kidney, and the opinion received confirmation from the fact that although at the time of the examination the patient had been passing clear healthy urine, almost immediately after the manipulation she passed a quantity which was thick and offensive. On the 15th October the patient was admitted into the Tottenham Training Hospital. During the preceding three weeks there had been more or less pyrexia. The tumour had increased in size, and the urine, which had varied, was clear. When thick, it had been found to contain a large quantity of muco-pus and many blood-cells, but no casts. The history of the case was briefly as follows:—Thirteen years ago the patient had a sudden attack of vomiting, and pain in the right side, which lasted for a week. A lump, about the size of an egg, was found by the doctor, examination of which caused great pain, followed within a day by its disappearance, nothing abnormal being noticed about the urine. About a year later she had a similar attack, the pain lasting eight weeks. At this time she was seized with a straining sensation, and passed a large quantity of thick urine, after which the lump disappeared; and until recently she has continued free from all urinary troubles.

Dec. 4th.—Since last note the patient has continued much the same. The urine has varied in quantity from twenty to forty-nine ounces in the twenty-four hours, it has been acid and free from albumen, and has been occasionally thick and offensive. The escape of pus with the urine has always been followed by a sense of relief to the patient. She has felt able to sit up easily in bed, whilst before the size of the tumour had impeded such movements.

In consultation with my colleague, Dr. Lichtenberg, it was determined to open the cyst through the abdominal wall, after inducing adhesion by the method advocated by the late Dr. Simon of Heidelberg. The most prominent part of the tumour having been selected, two long silver exploring trocars were introduced in a line with the anterior border of the axilla, at the distance of five centimetres from each other, and two others in a transverse direction midway between the two first, and two centimetres apart.

Offensive pus flowed from each cannula. A small quantity was thus allowed to escape, and afterwards the cannulas were stopped and carefully fastened in.

11th.—The patient had continued much as before the introduction of the trocars. The tumour was slightly reduced in size, and upon it a circular area, of which a line drawn from one vertically-placed needle to the other formed the diameter, was prominent. In this line, from needle to needle, an incision was carried through the abdominal wall and into the cyst; a considerable quantity of offensive pus escaped, and, on introducing a director, a stone was at once felt. This was grasped by a lithotomy forceps with some

¹ Archiv. f. Klin. Chirurg., Bd. xxii., Heft 2, 1878.

² Virchow's Archiv., 1879.

difficulty, owing to its size and position, but it was found impossible to move it. The incision being somewhat enlarged, the finger was introduced to its full extent, and the stone could then be just reached. It was felt to be very large, and so firmly fixed across the pelvis of the kidney, that it could not be moved. It therefore became necessary to relinquish the attempt, for, owing to the position of the stone, no ordinary instrument could be used to divide it. After this operation a large drainage-tube was kept in the sac, which was washed out twice daily with a solution of salicylic acid. The condition of the patient improved through the next three weeks, and the temperature was but little above normal.

Jan. 1st, 1880.—Being provided with a cutting forceps of which the blades could be introduced separately, I proceeded to remove the stone. The wound, which had considerably closed, had to be enlarged, and then the blades of the forceps were introduced. The portion B being cut off the stone was easily caught by a lithotomy forceps, and by a slight twist raised from its bed, to which it closely adhered. The finger then being introduced, another portion, A, was felt imbedded in its calyx, and was easily extracted. The calculus weighed 1·3 ounces, and appeared to consist of lithic acid with a very thin covering of phosphates. A slight bleeding followed, but this was soon over, and the drainage-tube was replaced.

Actual size, weight 630 grains.

In the evening the condition of the patient appeared satisfactory, but at 11 P.M. she began to complain of severe pain and became collapsed. After a while she rallied, and the next morning (Jan. 2nd) she seemed comfortable, but the abdomen was full. Temperature 100° in the morning, 101·5° in the evening.

Jan. 3rd.—Abdomen rather fuller; urine welled up through the tube. An enema was followed by good evacuation. Morning temperature 100·3°; evening 99·6°.

On the 4th the tympanites had increased. An enema was followed by another evacuation. In the evening she wore an anxious expression and felt sick. Temperature 101·3°. Afterwards the sickness increased so that nothing could be retained. Ice was given and the abdomen covered with lint frequently soaked in lead and spirit lotion, after which the sickness soon abated. The next day the temperature rose to 103°, and for three days after remained high, and there was great tympanitis, but being kept under the influence of opium she had little pain or sickness.

On January 12th the urine contained a good deal of pus, and smelled badly. The abdomen was getting less distended and softer. Morning temperature 99°, evening 100°.

13th.—Urine clear and pale. About this time it was noted that there was no albumen in the urine, which was always acid, and the condition of the patient was such as to lead to the expectation that she would make a good recovery.

15th.—The abdomen very soft and flat. She was beginning to enjoy food, but had a bad cold.

18th.—Coughed up rusty sputa. Evening temperature, 103·2°.

22nd.—Patient had become drowsy, and the urine was found to contain a large quantity of albumen, a subsequent examination revealing the presence of a multitude of tubercasts. After this the patient became gradually worse. The chest symptoms increased, there was oedema of the face and legs, and she died on the 31st of January, the thirty-first day

after the removal of the calculus. The wound through the abdominal wall had for some time been healed, except the sinus kept open by the drainage-tube.

At the post-mortem examination the apex of the liver was found to be firmly adherent to the upper extremity of the incision, and there were adhesions between the kidney and the colon, but no sign of general peritonitis. There was also near the incision a small collection of pus. The right kidney had shrunk to about its natural size; it consisted chiefly of thickened pelvis and calyces, little of the gland tissue remaining. The ureter was pervious, but much smaller than its fellow. The left kidney was congested.

Remarks.—Surgical literature does not appear to be rich in precedents for such an operation. The monograph¹ of the late Professor Simon of Heidelberg may, perhaps, be said to have exhausted the subject at the time of its publication. In this admirable treatise the author alludes to two cases published by Dr. Andrews and the late Mr. Callender in the 9th vol. of St. Bartholomew's Hospital Reports, and one of these is the only case alluded to which bears a close resemblance to that now under consideration. In this case Mr. Callender removed through the loin a large renal calculus, weighing more than 1·55 ounces; the patient, already worn out by pain and suppuration, dying three days afterwards. In the remarks suggested by it Mr. Callender says:—"I may also add that the term litho-nephrotomy has been used for the case here reported to distinguish it from other operations of a comparatively insignificant nature." Besides cases of nephrotomy (or the removal of stone from the kidney by cutting through the muscles of the back), to which allusion is made by Mr. Callender in the paper just referred to, one of a similar nature was reported in the *Gentleman's Magazine* for 1733.² It is there stated that "Mr. Paul, a surgeon at Stroud, extracted from the kidneys of a woman, by an incision through her back, a rough stone as large as a pigeon's egg, and made an entire cure, the first of the kind ever performed in this kingdom." But Mr. Callender also refers to an article on nephrotomy, so-called, in the *Cincinnati Lancet*, by Dr. Kearney, "in which, referring to the literature of the subject, he shows that the greater number of cases of so-called nephrotomy have been simply instances in which abscesses connected with disorganised kidneys have been opened, and the calculi extracted." How little of the surgeon's skill is required in these cases was once illustrated by the appearance of a renal calculus in a poultice which had been applied to a swelling in the loin of a patient whose case had not been thought to require medical assistance till this unexpected event alarmed his friends.

The advantages claimed for operations through the abdominal wall are the comparative thinness of the structures covering the tumour, and also that in this situation the incision being carried directly into the dilated pelvis, the substance of the kidney suffers less injury, and the risk of hæmorrhage is thereby greatly lessened. In the case of a large-branched calculus, it may be added that the attempt to withdraw it is made at much greater advantage through the pelvis of the kidney than in the direction of its branches through the substance of the kidney itself.

The operation practised in this case was designed and carried out by Simon for cases of pyonephrosis and hydro-nephrosis, and has been more recently performed by another German surgeon, and the success attending it in their hands led to its adoption in this instance.

High Cross, Tottenham.

COLOUR-BLINDNESS: ITS EXAMINATION AND PREVALENCE.

BY DR. B. JOY JEFFRIES.

IN THE LANCET of October 25th, 1879, Mr. Herbert W. Page regretted that he could not have been present at the Cork meeting of the Association to take part in the discussion on colour-blindness opened by my friend Dr. Swanzy. I also regret that I could not accept the polite invitation extended to me on that occasion. Had Mr. Page and myself met and taken part in this discussion I am assured he would not have written what he did in that

¹ Chirurgie der Nieren. 1876.

² Medical Times and Gazette, December 13th, 1879.

number of the journal. I first saw the article a few days since, or I should have replied to it ere this. Mr. Page's original article in THE LANCET of Jan. 13th, 1877, I commented on in the *Chicago Railroad Gazette* of May 9th, 1879; I then showed that there was no positive proof afforded of the engineer Pepper, in the Arlesby accident, not being colour-blind, which defect would have explained his neglect of the danger signal.

I would here call the attention of Mr. Page and others to what Professor Holmgren has written upon the points he touches on in this recent article, which points I am induced to criticise. A large part of the practical portion of Professor Holmgren's book will be found incorporated in my recent monograph, "Colour-blindness: its Dangers and its Detection," to be had of Trübner and Co., London. How the colour-blind see is there very thoroughly explained. Mr. Page says, "I, for one, should have no objection whatever to travel with a colour-blind engine-driver so long as he knew and could recognise—no matter by what sense—the colours indicative of danger, of caution, or the reverse."

The community will not agree with Mr. Page when they learn the truth—viz., that the colour-blind distinguish between a red and green light by a difference in intensity only. A locomotive engineer does not, moreover, have the two to compare presented at the same time. I have repeatedly tested the colour-blind in the lights by methods similar to Professor Holmgren's in order to prove to those interested that simply a difference in intensity made a difference of colour. A dim green becomes a red, a bright-burning red a green or white light. A correctly chosen depth of "London-smoked glass" will cause a colour-blind to think the lights coloured, and represent to them the red and green lanterns. Professor Holmgren says precisely the same: "Ask any superior official of a road if he would be willing to take charge of and run a locomotive, assuming the responsibility, when uncoloured signals alone were permitted, and a full light meant 'danger,' a medium one 'attention or caution,' and a strong one 'road clear.' If he says no, tell him that these are just the conditions under which every colour-blind engineer has performed his duties. The absurdity is evident at once."

I would recall the case of the Swiss engineer found by Dr. Minder, who turned a petroleum lantern up and said it was then white, part way down and then it was what others called green, and very low down it was a red light. This is also a perfect reply to Mr. Pole in his article on Daltonism in the May number of the *Contemporary Review*, 1880.

But Mr. Page says afterwards that he found a red-green blind engineer among the men sent to him to be tested. "The man had been an engine-driver for many years. He persisted in his knowledge of the signal-colours; but he was obviously red-green blind. When discharged from his place he admitted he was perfectly unable to distinguish these two colours." As Mr. Page would have risked his own life with such a driver he could hardly recommend the man's discharge. Fortunately, the authorities of the London and North Western Railway Company took a different view of the matter, as all railway officials will do when they finally thoroughly understand the conditions. It is unfortunate that an examiner does not appreciate the practical and subtle danger. How the colour-blind escape detection in everyday life, and how colour-blind railway employees (of whom there are about 3 per cent.) get on as they do, is of itself worthy of special study. I cannot, of course, enter upon it here. It is discussed in full in my monograph.

I have specially to criticise what Mr. Page has said in reference to Professor Holmgren's test. It does not seem possible that he has thoroughly understood it. He speaks of using twenty-two colour-cards as an "allied method," and "fulfilling the conditions of a good test." Professor Holmgren's is one of comparison, but wholly different from Seebeck's or Nilson's. In Germany, notably by Dr. Cohn of Breslau, the test has been used, not as directed by Professor Holmgren. An experience of over thirty thousand examinations has shown me the necessity of carrying it out *strictly as directed*, and that Professor Holmgren's very elaborate and minute directions are all worth carefully studying by anyone desirous of detecting colour-blindness with certainty.

But, as Professor Holmgren has well said, *seeing the test carried out by one familiar with it is a great advantage*, and in Sweden the railroad surgeons were therefore especially instructed by him *de visu*. Mr. Page says that he has spent *three-quarters of an hour* on one person with his own

and Stilling's cards. That case could have been decided in *five minutes* on the Holmgren's method by any examiner familiar with the test and the laws of colour-blindness, the colour-blind's perception being more limited is more strict than ours. Any variance from certain laws shows the experienced examiner at once that his directions are not understood, or that the examined is stupid. Directions are easily and quickly repeated, in pantomime if necessary from want of a common language, and no stupidity is insurmountable. Attempts at deception are as quickly recognised. All Mr. Page says about the colour-stupid, if I may use the expression, being likely to be classed with the colour-blind, assures me that he cannot be familiar with Holmgren's worsted test as carried out by the experts who have reported their results from different parts of the world. When tests calling for colour names have been used, of course from 10 to 20 or 30 per cent. have been reported colour-blind, for example, in France. Holmgren's test excludes all this, and tells us with absolute accuracy who are deficient in colour perception.

Mr. Page says, speaking of the colour-stupid, "to expect such persons to sort delicate tints of saffron, puce, lavender, or salmon, would be as absurd as to expect an untutored ear to appreciate and distinguish all the subtle varieties of note and tone which combine to make the richest melodies of Beethoven or Wagner." "Because uneducated and unlearned men cannot sort Holmgren's skein is, to my mind, the very poorest evidence of their being colour-blind. Not three weeks ago a man was before me who had a defect of this kind in an extreme degree, made evident by an examination of thirty-five minutes. Had he been left to himself to sort Holmgren's worsted, how great is the chance that he would have been regarded as colour-blind." Now Professor Holmgren's test calls for no such sorting. A peculiar shade of green is shown the examined, and by pantomime or words he is directed to pick out of the heap of little skeins of variously coloured worsteds, "all of that colour, lighter or darker." If colour-blind he quickly exposes himself. If not colour-blind he as quickly shows that he is not, or he shows that he does not understand the directions by disobeying the strict laws which govern the colour-blind's choice. The magenta worsted then decides which form of colour-blindness we have, if any. Children of four years, and adults of no education and hardly any intelligence, have never answered for me in ten minutes, and then only to convince the bystanders that they were not colour-blind. Mr. Page has had to devote three-quarters of an hour by the methods he used to a single adult. No wonder that he "looks with more than suspicion upon all statistics which have been drawn from the examination of hundreds of persons in a short space of time." For myself, I must defend the statistics given in my book, and my further ones since then reported up to thirty thousand. I perfectly understand and can detect ignorance of colours and lack of appreciation of colours, as also slowness of decision as to colours, due to want of education and familiarity with colour objects in everyday life. In all cases I watch most carefully the hands and face of the examiner, since they tell us so much. The great value of Holmgren's test is that we get at the effect of colour on the brain by the movements of the hands responding to this effect. I am entirely assured of the truthfulness of my results, and they correspond with those of the best European observers using the same method. By it uncivilised tribes have been examined with like results as to percentage of colour-blindness.

"Again," Mr. Page says, "if we are to arrive at any right estimate of the average of true colour-blindness, our examinations must be made amongst those who neither by lack of education nor by want of observation and cultivation can be included in the classes to which I have specially referred." All the scholars of the public schools of Boston and Baltimore whom I tested were above the primary classes. Besides these I tested of the professors and students of the Johns Hopkins University, Harvard University, Yale College, Brown University, Institute of Technology, Boston, Amherst College, 1436, finding fifty-six colour-blind, or about four per cent. Whilst of course I knew some stayed away from my examination because they were colour-blind, others came to find just what was the difficulty with their chromatic sense. Mr. Page's proposed test of the members of the British Medical Association at the Cambridge meeting will be a very good one if *all* will submit to the proof. The value of my work in our schools was, that *all* the scholars were examined. As congenital colour-blindness does not alter,

the statistics from the young are of the same value as from adults. With Holmgren's method the members can be tested at the rate of one hundred in an hour, if they would present themselves sufficiently rapidly to do what is required. In my examinations at the various colleges and universities above-mentioned I was surrounded by men of culture and science, ready to criticise each and every decision I gave. The truth is, however, that the proof of colour-blindness by Holmgren's method is so palpable as to leave no doubt in the mind of an intelligent observer.

One other point I must set Mr. Page right on. He says: "Investigators seem agreed that colour-blindness is much less frequent amongst women. Why? Because from their youngest days women have 'had to do' with colours in the petty adornments of millinery and dress; and it is only from lack of the same opportunities of cultivating it that men's sense of colour is inferior to theirs." Here Mr. Page is quite in error. The frequency of colour-blindness in males is a sexual difference, as abundant observation and thousands of tests have shown. The colour-blind girl or woman acts precisely as a colour-blind man when tested, notwithstanding all his training, &c. When being tested, the difference is that women and girls *work about twice as quickly as males*. As we go down the social scale they will more and more imitate men in their way of performing Holmgren's test, for instance. Mr. Page's suggestion is, of course, the one which immediately occurs in explanation of the extraordinary difference between men and women, but it is not the correct interpretation.

Whilst I was writing this, my friend, Colonel Head, surgeon U.S. Army, here stationed examining recruits, brought to my office a sergeant who was re-enlisting. The man was very intelligent. He told the names of colours with surprising correctness. He would have no doubt passed almost any examination based on this method alone. By Holmgren's test he had been in less than a minute shown to be completely red-blind by the examining surgeon, and in consequence of this defect he had been denied admission to the Signal Corps. My examination confirmed this diagnosis. To the green test he placed reddish-browns and greys; to the magenta, blues, and to the red, dark-brown and dark-green. The man knew of his defect from being laughed at for his mistakes at home. Strawberries and cherries he admitted he could not detect except by their form. I speak of this case here as showing that even in the aniline colours of the best worsteds we do not have *pure* colour. In all the lighter reds and greens there was enough of the colour this man could see—namely, *yellow*—for him to be able to say they were what other people called *red* and *green*, and so he did. And he thus voluntarily explained himself. Asked to match from the 150 skeins of worsteds the colour of the delicate new leaves of linden trees just outside of my window, he selected a yellowish-brown. Now, with aniline-dyed worsted we undoubtedly get the *purest* colours at present, aside from all other practical considerations. They far surpass in this respect the pigments on paper to be found in stores. Not having seen the twenty-two coloured cards Mr. Page tested with, I cannot state positively, but my experience would tend to show that there are but very few red- or green-blind who could not sort such cards correctly on account of the impurity of the pigments.

I entirely join hands with Mr. Page when he says: "Not less strongly than those who have expressed their views on the subject am I convinced of the vital moment of examining railway servants and sailors for sight and colour-blindness." I am striving for the establishment by law of this control in the United States. So far I have induced but one State, Connecticut, to pass legislative enactments. It is, of course, a mere question of time for all the others. Regulations concerning visual form and colour-blindness are in force in the United States army, navy, and marine hospital service; the last includes *all pilots*. The method adopted for medical officers is Holmgren's.

It is because I have been for the last few years especially engaged in urging legislative control that I have felt called upon to criticise some of Mr. Page's statements. The test for visual power I hold to be as necessary as that for colour-blindness, if not more so. I have the direct testimony of Professor Holmgren in Sweden, and Professor Donders in Holland, that these examinations should first and last be made by *medical experts*, and never left to "district inspectors." This in the interest of the *employé*, the shareholder, and the travelling community.

Boston, Mass., U.S.A.

TINEA TONSURANS ACCOMPANIED BY ALOPECIA AREATA.

By ALFRED SANGSTER, M.B.,
PHYSICIAN IN CHARGE OF SKIN DEPARTMENT, CHARING-CROSS
HOSPITAL.

J. G—, aged seven, according to his mother's statement first had ringworm about twelve months ago; his sister had ringworm three years ago. The patient came to the outpatient department with well-marked diffuse ringworm (chiefly over the occipital region), the affected surface being scaly and sparsely covered with hairs, some long, some short and stubble-like. Below and to the left of the superior angle of the occiput was a round patch of alopecia areata about the size of a crown piece. The patch had not quite the typical appearance of the last-mentioned disease, being somewhat pink and to a trifling degree rough; towards its margin were recognised the short, clubbed hairs characteristic of alopecia areata, while immediately beyond, for the greater part of the circumference of the patch, was the ringworm surface before alluded to.

Microscopical examination of such scales and débris as could be scraped from the bald surface showed epithelial scales with a few groups of spores, like ringworm spores. Examination of the clubbed hairs showed them to be highly pigmented, almost opaque. As regards the presence of fungus, nothing like the trichophyton was seen, but in such hairs as were less opaque there was a certain granular appearance (Hart. oc. 3; obj. 8 tube out), the granules in places being arranged in wavy lines, as if packed between the fibre-bundles of the hair. The specimens were mounted in glycerine, and still show the above appearances. Abundance of ringworm fungus was found in the hairs in the immediate proximity of the alopecia patch.

In the Pathological Society's Transactions (1874, p. 209), Mr. Waren Tay has recorded a case of alopecia areata associated with ringworm. In his paper similar observations by Hutchinson, Hillier, and Fox are alluded to, so that it would seem that the association is not a remarkably rare occurrence.

In the above-narrated case the presence of spores, like ringworm spores, among the débris scraped from the bald patch, might have been accidental, considering the proximity of the ringworm. However, most observers have found fungus like the trichophyton in the bald patches complicating ringworm. The question then arises, Are the bald patches true alopecia areata? bearing in mind how rarely (if ever) fungus is detectable in uncomplicated cases of the latter affection. If true alopecia areata, the further question suggests itself, Has this disease any relation to ringworm? And if so, what relation? Mr. Hutchinson has, I believe, long been decided that a relationship exists between the two diseases in question.

THE TREATMENT OF COMPOUND FRACTURE WITH COMPOUND TINCTURE OF BENZOIN.

By FERGUS M. BROWN, L.R.C.P. EDIN.

SOME time ago I read a communication on the treatment of the external wound in cases of compound fracture by the tincture of benzoïn, and I resolved to try it when I had the opportunity.

On the 27th of August, 1878, I was sent for to see Mrs. R—, a widow, who had broken her leg. As I was four miles from home in an opposite direction, and her residence was five miles from my house, I had to drive a distance of nine miles. I found her lying on the bed, the right tibia being pushed through the skin, about an inch protruding. I sent for the nearest medical man, but he was out; so I gave chloroform myself, and before I could reduce the fracture it was necessary either to enlarge the wound or saw off the projecting piece of bone. I first enlarged the wound, but being still unable to bring the ends into apposition, I was compelled to use the saw. Next I put it up in an inside and outside splint, bound with three straps made of

girth-web and buckles. The leg was then laid on its outside, and the wound simply covered with a few folds of lint steeped in compound tincture of benzoin. From time to time I had to desist during the operation for the purpose of giving another whiff of chloroform. There was no assistance save that of an ignorant female farm-servant, but my patient kept up well, though her age (sixty-eight) was against her. She had sustained the injury by falling from an apple-tree, where she had been gathering the fruit. Next day the leg felt perfectly comfortable, and after the first five days I saw her only about every third day. I did not move the splints or lint till Oct. 12th, on which day I put on a strong starch bandage. The following day, with the help of a crutch, she came downstairs. My last three visits were on Dec. 1st, 10th, and 31st; and now, with a high-heeled boot, she walks about, and attends to her housekeeping and farming as she did before the accident. There never was the least unfavourable symptom, nor was there a drop of pus.

My next case was that of a working timber merchant, Mr. L—, aged fifty, almost a total abstainer, who, in superintending the removal of a large tree, was struck by the small and free end swinging round, the horses being attached to the large end. Both bones of the leg were smashed into pieces. There was, however, but a small external wound about the middle of the fibula. I put the leg up in the same way as the last case. Next morning the whole leg from the knee to the ankle was one enormous blister; this I pricked, and covered the whole surface with lint soaked in tincture of benzoin. From the day I first saw him, 7th April, 1879, until he was out attending to his business in a starch bandage by the 1st July, he had not a single bad symptom. I should add he was the most patient man I ever saw; always took things in an easy way. He had a peculiarity I have not seen or heard of before: did he at any time eat an egg he was certain to have an action of the bowels within ten minutes.

I have not attempted to go more minutely into these cases, as there is nothing important in them; but occasionally country practitioners are at a loss for some remedy for wounds which will obviate the necessity of going every day long distances to dress trifling injuries.

UNIVERSITY COLLEGE HOSPITAL. (THROAT DEPARTMENT.)

REPEATED EXPECTORATION OF HYDATID MEMBRANE; NO
PHYSICAL SIGNS OF HYDATID DISEASE EITHER
IN THE CHEST OR ABDOMEN.

(Under the care of Dr. POORE.)

G. R—, aged twenty-nine, attended as an out-patient on April 2nd, 1879, taking with him some pieces of false membrane, which he stated that he had expectorated on March 26th. He had been under the care of Mr. Shoppee, of Kentish-town, and from that gentleman and the patient the following facts were elicited. About four years before he had been laid up for eighteen weeks with attacks of hæmorrhage from the lungs, for which he was treated by Dr. Peter Rawlins. On inquiry of Dr. Rawlins it was ascertained that these attacks were genuine attacks of hæmoptysis, and very severe. Dr. Rawlins further stated that a year previous to these attacks the patient had suffered from aggravated double pneumonia. Between the attacks of hæmoptysis and December, 1878, the patient enjoyed good health. Just before Christmas, 1878, during the prevalence of a sharp east wind, he coughed up a piece of membrane the size of half a crown. He continued his work, however (that of a night storekeeper on the railway), till the 19th of

March, 1879, when he was suddenly seized with an attack of hæmoptysis, in which he lost "a quarter of a pint of blood." He took to his bed, and on March 22nd coughed up a piece of false membrane, and on March 26th coughed up more false membrane. There was no history of dyspnoea. The membrane had on each occasion been coughed up suddenly, and the patient attributed his attacks to the east winds which were blowing at the time.

When seen at the hospital on April 2nd the patient looked somewhat anæmic and delicate. Temperature 99° 8'; pulse 100. Tongue rather big, and slightly fissured on the surface; tonsils red and slightly enlarged, with some amount of secretion lying in the crypts of the left tonsil. The mucous membrane of the epiglottis and larynx was rather red, and a little mucus could be seen lying in the fossa between the epiglottis and the tongue. The vocal cords were healthy. The trachea was plainly visible as far as the bifurcation, and appeared healthy. The urine was healthy, containing neither albumen nor sugar. A very careful examination of the lungs revealed a possible slight deficiency of expansion in the left infra-clavicular region, but no other abnormality of any kind. The signs elicited by percussion and auscultation were throughout those of health. No increase of liver dulness; abdomen normal.

The membrane was in three or four pieces, which collectively were sufficient to cover a crown-piece. It was grey, translucent, smooth, and could be split into several layers. It had the naked-eye characters of hydatid membrane, but under the microscope it presented a granular appearance, and neither fine laminations nor hooklets were detected at the first examination.

On April 24th he expectorated some more membrane, and again a small piece on June 16th, and on both these occasions the lamination characteristic of hydatid structure was plainly observable, although no hooklets were to be detected. Both these attacks of expectoration were attributed by the patient to a chill. On being asked for a description of his sensations when the membrane came up, the patient said that he felt "a fluttering at the chest" (pointing to the sternal region), and then the membrane came up with a cough, but without a feeling of sickness. He was sure it came up the windpipe.

Repeated examinations of the chest and abdomen revealed no physical signs, except the doubtful want of expansion of the apex of the left lung mentioned above. The patient had never been out of England.

Remarks.—The main interest in the case consists in the absolute absence of any physical signs indicative of an hydatid tumour in either the thoracic or abdominal organs, although the pieces expectorated would lead one to suspect that the cyst must have been of no inconsiderable size. The history of repeated hæmoptysis is quite characteristic of hydatid disease. The confidence with which the patient ascribed his attack to the condition of the weather is a point of some interest.

KENDAL COTTAGE HOSPITAL.

CONGENITAL ATRESIA OF THE VAGINA.

(Under the care of Mr. R. T. LEEMING.)

M. A—, aged nineteen years, married eighteen months, was admitted on Jan. 16th, 1879. She had never menstruated, but suffered from pains in the back and around the abdomen for several years.

On examination a hard tumour larger than a foetal head was found in the abdomen immediately above the pubes, and instead of a vagina there was a large rounded protrusion covered with mucous membrane tightly stretching the vulva. Examination per rectum proved that the abdominal tumour and vaginal protuberance were one.

An opening of three-quarters of an inch was made in the centre of the vaginal protuberance, and the confined menstrual discharge came away in the form of a very thick treacly fluid to the extent of over two quarts. The parts were covered well with carbolic oil. Two days later the incision was extended towards the meatus urinarius and perineum. On digital examination there was a perfect vagina and os uteri. A tent of carbolic tow was introduced, and external antiseptic dressings were used. The patient had a restless night, and on removing the dressing next morning about half a pint of albuminoid leucorrhœal discharge escaped. There were no symptoms of constitutional dis-

turbance until the second night after the operation, when the patient had several rigors. At 10 A.M. temperature was 103° F. On the dressing being removed a quantity of fetid pus, but of a laudable colour, escaped. On examination with the speculum this discharge was seen welling from the uterus, the os being dilated to the size of a threepenny piece, the parts being swollen. The vagina also participated in the general inflammatory action. The glands in both groins were enlarged and very tender on pressure. Instead of the ordinary dressing a speculum was now introduced and fixed, filled tightly with carbolic tow, so that the discharge might escape. Five grains of quinine, with ten drops of sedative solution of opium, were administered every four hours.

The inflammatory fever lasted for four days, the temperature, mornings and evenings, varying from 100° to 102°. The secretion now became of an albuminoid nature, which soon ceased with a subsidence of the irritative fever and swelling of the inguinal glands.

Before leaving the hospital, about three weeks after the operation, a normal menstrual flow took place.

The case was entirely lost sight of until April 29th this year, when on a journey into the country Mr. Leeming met her medical attendant, who informed him that the patient had been delivered of a full-grown female child after a natural labour, three days previously. Mr. Leeming visited her, when her expression of countenance, instead of being dull and half idiotic as previous to the operation, was bright and intelligent, and she said that after she left the hospital she was quite a different woman, and had never been so well.

TOTARA DISTRICT HOSPITAL, ROSS, NEW ZEALAND.

HYDATIDS OF LIVER; ASCITES; MULTIPLE ABSCESES;
DEATH.

(Under the care of Dr. R. H. BAKEWELL.)

J. B—, an Englishman aged forty-two, a miner, was admitted June 17th, 1878. This patient was in the hospital when Dr. Bakewell took charge in October, 1878. He was then suffering from black jaundice, the tint of the skin being that of a very dark mulatto. He was much emaciated and very weak. The urine was very dark from bile; the fæces were clay-coloured. The liver-edge could be felt at the level of the iliac crest on the right side, while the left lobe formed a prominent and conspicuous smooth and rounded tumour about three fingers' breadth below the umbilicus. He had previously been tapped several times for ascites, and the girth of the abdomen taken at the umbilicus was now 42½ inches. The respiration was short and difficult, and although he had been tapped only a fortnight before, he pressed for a repetition of the operation. His legs were anasarctous and very tense. On Oct. 3rd he was tapped. The quantity of fluid was not exactly measured, but it filled about three-fourths of an ordinary iron bucket. To take five grains of iodide of potassium three times a day; and to have iodine liniment applied over the region of the liver.

On Oct. 16th he had very much improved. The girth round the umbilicus was 37 inches, mostly caused by flatus, from which he suffered very much. Acupuncture of the legs had been performed on the preceding day. The dullness on the right side was increasing upwards, and was now complete up to an inch below the spine of the scapula; no respiratory sound could be heard in the lower half of the right lung posteriorly. There were friction-sounds and some pain; respiration was puerile in the upper half and on the left side. Distance from left nipple to umbilicus 12½ inches; from right nipple to umbilicus, 12½ inches; semi-circumference of chest, right side 17½ inches, left side 16½ inches.

On the 28th, the left lobe of liver was punctured with a fine trocar; nothing came away but turbid reddish serum, which contained blood and liver cells; very little pain was caused. At this time, owing to the marked prominence of the left lobe, there was a suspicion of cancer. Nothing like cancer-cells could be discovered. A copious pustular eruption appeared on the face. The iodide of potassium was omitted. A few days after, the eruption having disappeared, a smaller dose of the iodide of potassium, together with twenty minims of syrup of the iodide of iron, were given three times a day. Meanwhile there was no further accumulation of fluid in abdomen or legs.

On Nov. 2nd, the measurements were, from umbilicus to right nipple, 12 inches; to left, 11½ inches; semi-circumference same as on Oct. 16th; greatest girth of abdomen, 40 inches. On Dec. 2nd, measurements from right nipple to mid-sternum, 3½ inches; from left, 3½; from umbilicus to both nipples, 12½ inches; abdominal measurement as last month. To take five grains mercury pill daily. On Jan. 2nd, 1879, the circumference of the abdomen was 40 inches; from umbilicus to right nipple, 11½ inches; to left, 11½ inches. On Feb. 2nd, abdominal circumference was 41½ inches; from nipples to umbilicus, 12 inches. Some enlargement and tenderness of mammary glands.

At this time the enlargement was clearly owing to the gradual growth of the liver, and not to the accumulation of fluid in the peritoneum. The wasting and emaciation were so extreme that it was thought advisable to discontinue the iodine. Small doses of dilute nitro-muriatic acid in quassia were given instead, and the nitro-muriatic acid sponge-bath employed.

Up to March 7th he had been taking a large quantity of milk daily; this was diminished. Early in the morning of this day (about 3 A.M.) sudden and severe rigors occurred, with vomiting and pain in tumour. Temperature at night 104°. On the 11th the pain under the right scapula was severe. Cough was very troublesome. There was no expectoration, nor any moist sounds. The tumour was rapidly increasing, and the emaciation was very great. Acupuncture was occasionally practised in legs to relieve tension, but there had been no accumulation of fluid in peritoneum since October. On the 12th fluctuation was well marked in the right eleventh costal interspace. This was explored with a hypodermic syringe, and clear fluid was withdrawn. The spot was then tapped, and about three ounces were taken; no more could be obtained, though the trocar was driven well home. That day and the next rigors occurred, and two or three more exploratory punctures were made, but the abscess could not be reached, and nothing but hydatid fluid was removed. On the morning of the 13th the surgeon-superintendent was called up by the night watcher in the belief that the man was dying. Respiration was very rapid and shallow, the pulse small, feeble, and rapid, and the patient presented a most ghastly spectacle. His colour was darker than ever, and he was emaciated to the last degree. Nevertheless he still persisted in saying that he should get well, and that if he could get rid of the swelling he should be all right. With the exception of this delusion his mind was clear almost to the last, but about 8 A.M. on the morning of the 14th he became semi-comatose, and died two hours afterwards.

Necropsy, made about four hours after death.—Weather very hot. No signs of decomposition. Hypostatic congestion of all the lower parts of the body. Skin of an intense yellow colour, verging upon brown. On opening the abdomen the liver was found to form an immense tumour overlying most of the abdominal viscera. An incision was made into the left lobe, and some pints of pus came away. Another abscess was opened before the liver was removed, and also a large hydatid mother-cyst in the right lobe. With some difficulty the liver was removed, but this could not be done without opening another hydatid cyst. It was then weighed, with most of the loose hydatids, of which there were hundreds, varying in size from that of an orange to less than that of a pea. It then weighed 16½ lb. It was thought that if the liver had been removed without opening the abscess and cysts, it would have weighed at least 20 lb. The kidneys were deeply stained with bile, but were otherwise healthy. The right lung was much compressed, and in a state of red hepatisation. The left was emphysematous, but otherwise healthy. The other organs presented nothing worthy of particular notice. The brain was not examined.

Remarks by Dr. BAKEWELL.—This case was somewhat remarkable on account of the enormous development of hydatids without their having caused perforation of the diaphragm, or any part of the peritoneal investment of the liver. Hydatid tumours of the liver are exceedingly common in these colonies, but usually long before they attain the size they did in this case they perforate the liver, and are discharged through the lung, or an abscess is formed which breaks into the bowel. Those cases are the commonest in which the diaphragm is perforated. In such the disease, though long and tedious, is often cured. In one instance which came under my care in private practice the patient had been spitting up hydatids from the lungs for eighteen months. The symptoms all ceased after the continuous use

of a decoction of the tree-fern root for six weeks. It is noteworthy that there was no trouble from ascites after iodine had been employed externally and internally, although the growth of the tumour was only for a time arrested.

The diagnosis of hydatids of the liver is often attended with much difficulty. The presence or absence of the hydatid fremitus on percussion depends on the greater or less depth of the hydatid in that portion of the liver which is percussed. Hydatid fremitus was not observed in J. B.—'s case until a few days before death, and then an exploratory puncture proved that a hydatid cyst was situated immediately beneath the walls of the chest, with nothing but a thinned diaphragm between it and the intercostal muscles.

HYDATIDS OF RIGHT LUNG; OBSTINATE DRY COUGH;
FORMATION OF WHITE FIBRINOUS CLOT IN HEART;
DEATH.

J. M. S—, a Swede, male, aged fifty-three, a gold miner, was admitted Dec. 4th, 1878. On admission he complained chiefly of internal hæmorrhoids, which bled a good deal. He was a fair-complexioned man, of highly nervous temperament, had led a solitary life, being what is called amongst miners a "halter"—that is, working by himself. He had been very unfortunate, and was very silent and reserved. He complained of a troublesome cough. An examination of the chest was carefully made, and repeated daily after admission for some time. Nothing could be detected except a small patch somewhat dull, situated posteriorly on the right side, just below the spine of the scapula. The patch was of an oval shape, and not larger than the longitudinal section of a walnut. Breathing was coarser over this spot, and local resonance was slightly increased. The uvula was elongated, and as it was thought that this might have something to do with the cough, a gargle of capsicum and tannin was ordered, together with some compound tincture of camphor and sulphuric acid.

On Dec. 9th, the cough being still troublesome, a small blister was applied to the right side. On the 12th the cough was still troublesome. Sputa very slight, but just tinged with blood. Ordered four ounces of wine daily, twenty minims of tincture of belladonna thrice daily, and to continue the gargle. On the 16th the cough was as bad as ever, and disturbed the other patients. There was no change in the lung. It was found that when his attention was drawn off the cough ceased for a time. On Dec. 22nd the dulness had extended greatly; there was no notable hæmoptysis, but the sputa were white, and occasionally tinged. On the 28th considerable hæmoptysis occurred, and the dulness was rapidly increasing. From this time until his death various remedies were tried to allay the cough, but all of them afforded only temporary relief. He had porter, milk, cod-liver oil, and good meat diet, but still he continued to grow weaker and thinner. On January 20th the breath had an extremely offensive odour, suggesting gangrene of the lung. The right chest measured one inch more than the left in line of nipples. There was considerable œdema in the right lumbar region; none in the left. On the 23rd there was dulness with complete absence of respiratory murmur over the right chest posteriorly from the spine of scapula. The dulness was bounded by the posterior wall of axilla. Fœtor of breath persisted.

Though the man was obviously growing weaker, there was nothing to indicate any immediate danger, or to require any particular watchfulness at night. On the night of the 25th he was seen by the surgeon-superintendent as usual. On the morning of the 26th he was found sitting up in his usual posture, quite dead. One of the patients in an adjoining ward had heard him coughing until about 1 A.M., but no sound was made that led him to suspect anything extraordinary.

Necropsy.—A hydatid cyst was found occupying the lower half of the right lung. The walls of the cyst were in part gangrenous. The contents were a number of hydatids and foul-smelling pus, mixed with fluid. The liver was healthy. The right auricle and ventricle were filled up with white fibrinous clots. Nothing else noteworthy was observed.

Remarks.—Although the symptoms on admission were ambiguous, and the physical signs obscure, yet the persistence of the cough, coupled with the existence of a small but well-defined patch of dulness in the posterior part of the right lung, just below the spine of the scapula, suggested a hydatid tumour. For some time it was doubtful whether it

might be that or a nodule of cancer, or possibly lobular pneumonia undergoing caseous degeneration, but the comparative rarity of either of these two diseases, and the frequency of hydatids, rendered the hypothesis of hydatid disease the more probable. In view of the increased dulness, the hæmoptysis, the fetid breath, without any of the physical signs of a cavity, or of pneumothorax, the diagnosis was rendered all but certain. Dr. Bakewell was about to aspirate the dull part of the chest, to remove the fluid, and had determined to do so on the very day the patient died. Fortunately the operation was not performed.

A third case of hydatids of the lung and liver was admitted in a moribund state, but as the friends would not allow a post-mortem it is not worth while to record the symptoms.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Basic Cavity of the Lung treated by Paracentesis.

THE concluding meeting of this Society for the session was held on the 8th ult., J. E. Erichsen, Esq., F.R.S., President, in the chair. Only one paper was read and discussed. It dealt with the comparatively novel subject of the operation of paracentesis of pulmonary cavities, and was contributed by Dr. R. Douglas Powell and Mr. R. W. Lyell. The case recorded was one of basic cavity following on pneumonia, and complicated with bronchiectasis. The operation afforded remarkable relief for some weeks, when the expectoration again became fetid, and death ensued from an attack of pleuro-pneumonia of the opposite lung. The paper discussed at length the indications for the operation, and reviewed the cases hitherto published.

The following is an abstract of the paper on a case of Basic Cavity of the Lung treated by Paracentesis, by Dr. R. DOUGLAS POWELL and Mr. R. W. LYELL. The case related was that of a man aged forty-nine, of previous good health but intemperate habits, who, in December, 1878, had had bronchitis, followed, in the ensuing February, by pleuro-pneumonia and fetid expectoration. He improved after a time, but relapsed again in July, and in August was admitted into the Middlesex Hospital under Dr. Powell's care. On admission the physical signs showed consolidation of the lower lobe of the right lung, with excavation of its central portion, the cavity signs being centred about the level of the seventh dorsal spine in the line of the angle of the scapula. There was considerable hectic, diarrhoea, and anorexia. The breath and expectoration were extremely fetid, the latter being muco-purulent in character, and very abundant, amounting to about one pint in the twenty-four hours. The area of excavation having been carefully marked out, the operation of paracentesis was performed by Mr. Lyell on Sept. 11th. A medium-sized aspiration-trocar was first thrust in at the eighth space mid-scapular line, and a free incision having been made through the tissues down to the intercostal membrane, the fine trocar was withdrawn, and a full-sized hydrocele trocar inserted, which, after slightly enlarging the opening, was in its turn removed, and a large drainage-tube introduced. Carbolic dressings were applied. A moderate quantity of secretion escaped from the wound (which gave rise to no serious bleeding), and the discharge subsequently from the tube, although free, was never abundant. The expectoration and cough, however, at once almost entirely ceased. The wound was dressed daily under the carbolic spray with the view of disinfecting it and the cavity, and injections of Condy's solution were used. On October the 2nd there was some return of fetor of breath, that of the discharge from the tube having never quite been corrected. Some trouble was occasioned by the tube slipping out, its reintroduction being hindered by encroaching granulations, and the tube was felt to strike against some impediment deep in the lung. The channel was kept dilated, however, and the patient improved in strength, and on the 20th was transferred to the Brompton Hospital. Fœtor of sputa returned towards the end of the month, however; although the amount expecto-

rated continued to be very scanty, the patient lost ground rapidly, and was finally seized with pleuro-pneumonia on the opposite side, of which he died on the 31st October, fifty days after the operation. The post-mortem examination revealed the presence of several intercommunicating cavities in the lower lobe of the right lung. This lobe was firmly adherent throughout, and a drainage-tube passing through the eighth intercostal space entered a contracted cavity which was connected with the main cavity by a short dilated bronchus. This small cavity must have been closely subpleural and was the very lowest of the series; although at so high a level as the eighth space, it was only separated from the diaphragm by $\frac{1}{2}$ inch. It was evident that in contracting upon the tube the wall of the cavity had come in contact with and partially occluded its extremity. The rest of the lobe was densely consolidated by fibroid growth surrounding bronchiectatic cavities. There was broncho-pneumonia and effusion on the left side. The rest of the lungs was emphysematous. In their remarks upon the case the authors comment upon the infrequency with which the base of the lungs has been tapped, and point out that the immediate cessation of cough and expectoration after operation in this case was a fact very encouraging to future interference with such cavities under more favourable circumstances, and afforded a valuable hint respecting the importance of disinfecting lung cavities. For it was clear from the small amount of the discharge compared with the great previous quantity of expectoration that the bulk of that expectoration had been yielded by the bronchi, irritated by the acid fluids and gases in their passage from the cavities. Whilst advocating the puncture of chronic basic cavities in suitable cases, the authors deprecated interference with apex cavities, on the ground of its being rarely necessary or useful, and are averse, save in exceptional instances, to making incisions into acute basic abscesses of the lung. In the present case, however, the operation had undoubtedly been postponed too long, the patient having come under observation too late. The diagnosis of the case from empyema was touched upon, and the several steps of the operation discussed; the use of a large trocar in preference to the knife being advocated. In future cases, too, the authors would prefer to choose the centres of the cavity rather than its lowest point for puncture where it is situated in the posterior lobe of the lung.—Dr. SYMES THOMPSON remarked upon the clearness with which the authors had stated the difficulties of the operation, as well as its advantages and disadvantages. They had shown how the cases to be selected should be those of a chronic disease—owing to the probable non-adhesion of the pleura in acute cases, which might get well if left alone. The time at which operative interference was called for was an important question; it should not be postponed too late, nor on the other hand hurriedly undertaken, when there was a fair prospect of recovery without it. Owing to the diagnostic difficulties the operation was not likely to become a common one, for cases in which a pulmonary abscess sufficiently superficial could be diagnosed are few. But when there were grounds for believing in the existence of such a cavity, with adherent pleura and condensed lung, the question might be entertained; and the paper read would aid in the conclusion arrived at.—Dr. BARLOW said that no treatment of suppurating cavities could be satisfactory which did not allow of free drainage. In this case the opening was a sinuous one. He presumed that in such cases a complete cure could not often be looked for; but if free vent were given to the fetid pus, life might be prolonged by operation. To afford this free escape he would urge, from his experience of empyema, the making of a double opening, which dispenses with the necessity of injections (and he had seen two or three patients die suddenly during injections into the pleural sac). Then, as one can never be certain in what way a sinus is going to heal, the double opening allows the surgeon to remove the tube when nature indicates. He had observed that those cases of empyema which were treated by single openings took longest to heal. Another point was the fixation of the tube. He had known it to escape into the cavity, and had also found it difficult to replace it if it had become pushed out of the sinus. When a single tube is used the plan at the Children's Hospital is to tie the tube in and to leave it flush with the surface—a point insisted on by Mr. Lister. The method of stitching the tube by sutures to the edge of the wound answers at first, but he had seen such stitches give way. With a double opening no such difficulties arise.—Dr. SILVER pointed out that the point under discussion was

the operation of tapping the lung.—Dr. C. T. WILLIAMS said it was important to discriminate the nature of the case. Cases of bronchiectasis following interstitial pneumonia were not very suitable for operation, since in them the alteration of the bronchial tubes was general throughout the lung, and the cavities mostly multiple; so that if tapped in one place, the expectoration might still continue fetid. In one case he had recorded a needle was passed into a bronchiectatic cavity, without result; and a second tapping succeeded in evacuating the contents of a limited empyema, which might have been caused by the original paracentesis. In ordinary phthisis, the apex cavities, as a rule, drain themselves, so that no operation would be called for in them. The case referred to in the paper where Mr. Erichsen operated was one of phthisical excavation and profuse expectoration, with pyopneumothorax. In that case it would have been impossible to have used a short tube, as suggested by Dr. Barlow. He concluded by hoping that the operation described in the paper would have a fair trial.—Dr. REGINALD THOMPSON said the most important point was the conservative side of the question—the attempt to prevent the opposite lung from becoming infected with septic matter inhaled from the affected side. When that risk was imminent it was clear the operation was justifiable. The procedure might be adapted to another class of cases—viz., when rapid and extensive sloughing of one lung takes place in individuals of broken-down constitution. In such a case timely puncture might prolong life by preventing the secondary involvement of the other lung.—The PRESIDENT said that, from a surgical point of view, the essential thing was to maintain drainage. Antiseptics were not needed, and were useless in such cases. In the case he saw with Dr. Williams the fetor was excessive before operation; but after the free opening had been made into the chest this fetor almost at once ceased. To maintain drainage the opening should be very free, and the tube made of rigid material, so that it might not be compressed by the chest wall. In the case mentioned he used a vulcanite cannula. The injection of antiseptic fluids only excited irritation. As to the operation itself, he would adopt Mr. Hilton's plan of dilating the wound by dressing forceps rather than that of free incision, so as to avoid hæmorrhage. In Dr. Williams' case, rapid and very extensive subcutaneous emphysema almost immediately set in, being increased by violent cough. No ill consequences ensued, for although the gas which entered the tissues must have been charged with foul products, it was perfectly innocuous.—Mr. HOLMES added, that in a case of emphysema from communication with the rectum no irritation was produced in the tissues by the gas.—Dr. POWELL, in reply, said that the operation was one about which so little was known that it required all possible light to be thrown upon it. He agreed with Dr. Symes Thompson as to the difficulty of deciding when to interfere. In this case the disease was shown subsequently to consist of bronchiectatic cavities; but he could not help thinking it had originated in an abscess of the lung, to which the bronchiectasis was secondary. He had at present under his care at Brompton Hospital a patient with a large basic cavity, and, in addition, widespread disorganisation of the lung. It would be risky to attempt a double opening into these cavities. In the present case the opening was really made too low; an outlying cavity was tapped, but if the opening had been higher it would have entered the middle of the main cavity. The tube was made flush with the surface. The immediate cessation of expectoration after the tapping was remarkable, showing that a small amount of fetid acid material would set up much bronchial irritation. He was familiar with the cases of sloughing pneumonia mentioned by Dr. R. Thompson; possibly in future such cases might be dealt with on this plan. The drainage was the pith of the matter, and antiseptics were found in this case to set up much irritation. Various kinds of tubes were used in the case, the last employed being one with a wire in it.—Mr. LYELL, in reply, said that the plan pursued in opening into the lung was of great importance. In this case he used a trocar and cannula as a preliminary expedient for tapping the cavity; so that in case it had not been reached at first it might have been attacked at another spot; and there was less risk of hæmorrhage on this plan. All kinds of tubes were used; and he found the most convenient form for security was one with a large shield by which it could be strapped on to the chest. If he were to do the operation again he should prefer a metal tube. Mosler in his case used a silver tube. It was impossible to have made a double

opening; nor did the condition of the patient permit of the operation being prolonged. The cessation of fetid expectoration showed that the cavity had been effectually drained. The result of using injections was to show that they were so irritating as to be a drawback rather than otherwise. Mosler employed an atomiser for this purpose—a preferable plan to syringing. The expectoration did not become fetid again until after the lapse of three or four weeks.

The Society then adjourned until October.

OBSTETRICAL SOCIETY OF LONDON.

At the meeting on June 2nd, Dr. W. S. Playfair, President, in the chair,

Dr. CHALMERS showed for Dr. McLaurin a Fœtal Monster in its seventh month. There was a single head, and the bodies were united in front as low as the umbilicus. The monster presented by the feet, and was expelled by the natural forces.

Dr. CHAMPNEYS showed a specimen of a Retroflected Uterus, in which the wall on the concave side of the curve was much thicker than the other.

Dr. GALABIN showed Microscopic Sections illustrating the Pathological Anatomy of Erosion of the Cervix. The first closely approximated to true ulceration. Epithelium was entirely lost, as well as the normal papillæ, and the tissue resembled granulation tissue. It was bounded by intact squamous epithelium towards the os as well as on the other side. The second resembled an extension outwards of a surface resembling the interior of the cervical canal, but with hypertrophy of tissue in a villous form, as described by Ruge and Veit. The apparently eroded surface was covered with cylindrical epithelium.

Dr. CLEVELAND showed a full-term Child, the subject of a large Encephalocele, from the practice of Mr. G. S. Walker of Kilburn. The mother had a severe mental shock about a fortnight after quickening. The tumour was about the size of a cocoanut. The child lived forty-four hours, and died of inanition.

Dr. T. CHAMBERS showed a Tumour diagnosed as Fibro-cystic of the Uterus, which he had that day removed with the ovaries by abdominal section antiseptically. The incision was twelve inches. The broad ligaments were transfixed and tied, the cervix enclosed in the author's parallel clamp, the tumour cut away, and the cervix afterwards transfixed and tied. One artery was not controlled by the clamp, and required separate ligature.—Dr. BANTOCK said that in applying a parallel clamp to the cervix the tissues at each side, containing numerous vessels, could not be sufficiently compressed to prevent bleeding. Some circular pressure was necessary. Moreover, he had found that, however tight ligatures might be at first, they become loose after a time on account of the nature of the uterine tissue.

Dr. C. H. CARTER read notes of two cases of Extra-uterine Fœtation, with results. The first patient, aged thirty-eight, was admitted as an urgent case of extra-uterine fœtation. She was in a very critical state; pulse 150. There was a tumour towards the right side as high as the umbilicus, and continuous with a soft doughy mass occupying the pouch of Douglas. Menses had ceased, and she had supposed herself pregnant in December, 1878. In April, 1879, she was in St. Bartholomew's Hospital, under Dr. M. Duncan, with supposed retroversion of the gravid uterus, and an attempt was made to push up the swelling. At the end of August she passed a large substance by the vagina, and was readmitted in September. Extra-uterine fœtation was then diagnosed, the fœtal heart having been heard on her first coming to the out-patient room, but afterwards ceasing. The uterine probe entered six inches into the abdominal hardness, and the point felt as if less than the thickness of the unimpregnated uterine wall covered it. The patient left against advice. A fortnight before her admission, under the author, on January 13th, 1880, she was seized with abdominal pain. A superficial abscess, pointing near the umbilicus, was opened on the 26th, and fetid pus and debris let out. On Feb. 12th a piece of bone was felt by a probe, the opening was enlarged, and the fœtus extracted. The placenta did not come away with the fœtus, and the discharge was very offensive for three days. A discharge

took place per vaginam on the 23rd, and the patient afterwards quickly recovered. The second patient, aged thirty-four, was admitted in July, 1879, for what was supposed to be pelvic cellulitis. The uterus was fixed, and there was a swelling on the left side up to about an inch above the iliac crest. She went out on October 8th, the swelling being smaller. At the end of October some fetid bones were passed per rectum, and she was readmitted in December. Discharge of bones went on until May, when some large flat pieces were nipped in two, and extracted. The author thought that if he had diagnosed this case in the earlier stage he should have been justified in endeavouring to evacuate the cyst through the abdomen. He said that the incision was not made with strict antiseptic precautions, though the cavity was frequently washed out with carbolic lotion. He had not examined the fluid for bacteria.

Dr. GRAILY HEWITT presented a report on Sixty-seven Cases of Uterine Distortion or Displacement, treated during seven years at All Saints' Institution for Ladies suffering from illness, 127, Gower-street. The cases were those treated during seven years, from May, 1872, to May, 1879. The patients were governesses, ladies dependent on their own exertions in various ways, wives of curates, &c. Age varied from eighteen to thirty. The cases comprised various forms of uterine displacement, associated often with great weakness, with a slow but disguised form of starvation, and more or less complete inability to walk or move about in the ordinary manner. In several cases the patients were bedridden, in others power of locomotion was so impaired that employment had to be relinquished; in others the malady, though not so severe, had been found intractable. Great weakness, more or less inability to walk (uterine dyskinesia), and general malnutrition were coupled with various degrees and forms of uterine distortion and displacement, causing pain on locomotion, sickness, menstrual irregularities, &c. The sixty-seven cases are resolved into two classes—(a), 45 of anteversion or flexion; (b), 22 of retroversion or flexion. (a) Thirty single, 15 married. Severity of some of these may be judged of by the time required for treatment. One, a case of chronic invalidism, was under treatment fifteen weeks at intervals spread over thirteen months. Another, whose most distressing symptom was obstinate sickness, was cured satisfactorily only after two years and a quarter, and spent twenty-five weeks in the institution. A completely bedridden case, with hysterical symptoms of long standing, was under treatment over one year, thirty weeks in the institution. The cure was finally complete in these cases. Other similarly obstinate cases were mentioned. In one case of chronic anteversion not long under treatment circumstances prevented a return for further treatment, and after upwards of a year the affection proved fatal. (b) Retroversion or flexion cases, fourteen single, eight married. One patient required fourteen weeks' treatment, the chief symptom being sickness. In another treatment was afforded at intervals during over two years, the uterus was much retroflected, and the ovaries dragged downwards; locomotion, impossible at first, was finally fairly restored. One was a case of almost complete paraplegia complicated by a spinal injury, but the power of locomotion was greatly affected for the better under treatment. Of the whole sixty-seven a very large proportion were restored to health and usefulness. The treatment adopted was as follows: The patients were kept recumbent, in the dorsal position in cases of forward displacement, in the semi-prone position in cases of backward displacement. In most of the cases, semi-starvation being recognised as existing, sometimes of some years' standing, food easily assimilable was frequently given, sometimes every hour; in case of sickness, nutrient enemata. Some cases required months of careful dietetic treatment to restore the general strength. To restore the uterus to its proper condition simple measures were employed; in some cases positional treatment, such as prone or dorsal or knee-elbow position, systematically and frequently. But in most cases other measures were necessary. In cases of forward displacement the cradle pessary, in backward the Hodge pessary, were employed. The sound was used at intervals to aid in restoring the uterus to its proper shape when that organ was found hardened in its distorted shape. The sponge bath, frictions of the skin, great care to prevent constipation, were often subsidiary measures. The principles adopted were, to gently elevate the fundus uteri, to straighten the canal, to avoid what was likely to interfere with mechanical restoration, to nourish the frame and harden the tissues by careful feeding, and thus harden and set the uterus in its

normal shape. The cases offered (1) strong evidence of the connexion between the health of the body generally and that of the generative organs, especially of the uterus; and they show that, if the strength be not adequately sustained during the growing age, the uterus is liable to suffer, and to become weak and incapable of resisting the physical strain and tension of an ordinary active life. It was quite easy to trace in the early history of the cases this almost universal predisposition. These considerations showed that local uterine treatment cannot be expected to be permanently successful, unless measures be taken to remedy the extreme general weakness. The physical change most evident in the uterine tissues in cases of prolonged insufficiency of food is softening and loss of tonicity. (2) A second general conclusion is the remarkable frequency with which these patients were affected with physical powerlessness, an incapability of locomotion varying in degree. This peculiar symptom the author has termed "uterine dyskinesia." It was present in a marked form in almost all the cases, and in most it was the prominent symptom. Physical exertion produces a temporary exaggeration of the existing internal malady, gives pain, and is thus given up; hence a helpless invalidism in many cases. This physical inability is not imaginary or fanciful, though often erroneously so considered. (3) Another general remark is as to the frequency of sickness or nausea as a troublesome symptom and complication in these cases. The cases prove that distortions and displacements of the uterus when aggravated or increased temporarily or persistently by particular exertion are liable to produce an exceedingly troublesome form of sickness or nausea. This is a reflex symptom. A secondary effect is starvation. Later on the stomach itself becomes diseased, and the power of secreting gastric juice is more or less lost.—Dr. GERVIS had seen cases in which the postural method had been adopted for many months with only the result of impairment of the patient's health. He would fear that, if fully carried out, it would benefit the position of the uterus only to the damage of the patient's general health. Dr. Hewitt spoke of leaving pessaries undisturbed for several months. He thought they ought to be removed at moderately short intervals, for the sake of observing the position of the uterus as well as for cleanliness. His belief as to flexions was that their importance largely depended upon the amount of obstruction induced by them in the cervical canal. He had for some time treated very few cases of ante flexion with pessaries, but rather by dilating the cervical canal with uterine bougies, with a very satisfactory result.—Dr. ROUTH believed that uterine disease, as a cause of mental symptoms and even insanity, was often overlooked. But he could not concur with the practice of keeping patients so long reclining, and thought that general debility and other symptoms were likely to be aggravated thereby. He differed also as regards the use of the cradle pessary, from which he had never seen any good result. In the case of ante flexion he believed that nothing short of an intra-uterine stem would cure the patient.

On the motion of Dr. BANTOCK, seconded by Dr. ROGERS, the discussion of Dr. Graily Hewitt's paper was then adjourned until the next meeting.

Reviews and Notices of Books.

Chirurgie Antiseptique: Principes, Modes d'Application et Résultats du Pansement de Lister. Par le Dr. JUST LUCAS-CHAMPIONNIÈRE, Chirurgien de la Maternité l'Hôpital Cochin. Deuxième édition. Paris: J. B. Baillière et Fils. Londres: Baillière, Tindall et Cox. 1880.

Antiseptic Surgery: an Address delivered at St. Thomas's Hospital, with the subsequent Debate, &c. By WILLIAM MACCORMAC, M.A., F.R.C.S.E. & I., Surgeon and Lecturer on Surgery, St. Thomas's Hospital; Consulting Surgeon to the French Hospital. London: Smith, Elder, and Co. 1880.

It is a characteristic circumstance that the antiseptic method of dressing wounds should have been conceived and perfected as a scientific system by an English surgeon, and that an account of its history and a full description of all its details should have been published first in Germany and then in France. Though more than fourteen

years have elapsed since Mr. Lister recorded his earliest attempts to devise an antiseptic mode of dressing wounds, it is barely a month since the first systematic work on the subject in the English language left the press. Germany has long possessed a copious and extensive literature relating to antiseptic surgery, and France has not been far behind, but in England the only descriptions that have been given have been such as may be gathered from the lectures, discussions, and records of cases published from time to time in the various medical periodicals. Even now, the appearance of Mr. MacCormac's book is an accidental phenomenon, arising out of an address which the author delivered at St. Thomas's Hospital before the members of the South London Branch of the British Medical Association. That address, our readers may remember, formed the text of an interesting debate, in which a large number of the leading surgeons of the metropolis and of the provinces took part, and afforded likewise an opportunity for Mr. Lister to reply to some of the more recent criticisms of his method. There was, we are told, at first no thought or intention of reproducing in print either the address or the debate, but, acting on the suggestion of Mr. Spencer Wells, Mr. MacCormac agreed to undertake the task of editing the remarks and comments of the various speakers who took part in the discussion, with a view to publishing them in a separate form. The remarks of each speaker have been revised, corrected, and occasionally amplified. In order to increase the general interest of his book, and to make it more useful to students and practitioners desirous of becoming acquainted with Mr. Lister's antiseptic method, Mr. MacCormac has added a short statement of the more important points connected with the theory on which the method is based, and a description of the antiseptic materials in common use and the manner of their preparation. The last chapter is devoted to some of the practical applications of the antiseptic system, including its employment in military surgery. Altogether Mr. MacCormac's book must be regarded as a valuable and interesting contribution to modern surgery. It is not only a compendium of the opinions of the best surgeons of the present day on the nature and causes of wound diseases, and the best modes of preventing them, but it contains a large yet sifted mass of illustrative facts gathered from every trustworthy source. There is scarcely any question of practical importance that Mr. MacCormac has not fully considered. His book must long remain the best, as it is the first, in our language on the subject with which it deals.

Equal praise must, however, be given to Dr. Lucas-Championnière's work. Though differing somewhat in structure and plan, the aim of both the works named at the head of this notice is identical—namely, to make known the principles of Mr. Lister's antiseptic method, and to teach the best mode of carrying it out in practice. It is needless to say that both authors are uncompromising believers in the theory of the germ-origin of purulent and putrefactive wound-diseases, and in the efficacy of Mr. Lister's plan of obviating them. Both speak with the authority of experience, and with a confidence inspired by success. Dr. Lucas-Championnière, after describing the slow but steady growth of opinion in favour of Listerism during the past four or five years in the Paris hospitals, declares that in some of the hospitals formerly reputed very unhealthy the most formidable operations are done with the same security as if in the purest air of the country. He says that Mr. Lister's method affords all the external advantages of the country, combined with all the resources of well-appointed hospitals. Like other advocates of Listerism, he claims for this method a complete immunity from purulent infection. Nélaton, who was among the most successful of operators, was wont to say that the man who should abolish purulent infection

would deserve a gold statue. Dr. Lucas-Championnière would award this statue to Mr. Lister, inasmuch as purulent infection has disappeared from the list of wound complications wherever Mr. Lister's plan is properly carried out. Dr. Championnière promises six additional advantages to those who adopt Listerism—namely, a disappearance of the accidents of wounds even in the worst media, a regularity of repair hitherto unknown, a surgery without suppuration, habitual primary union of wounds, an unprecedented rapidity of healing of wounds, and the possibility of safely performing operations otherwise dangerous and even culpable. We are assured that by strictly adhering to Mr. Lister's plan we may not only diminish the mortality after operations, but ensure more speedy recoveries, and with less risk and damage to the general health. This is an aspect of the question that has not yet been adequately considered. If we may trust statistics (and within certain limits we may trust them), the net gain of life from the antiseptic plan of dressing wounds must be very great. The precise amount is not estimable. But the bare question of life or death is not all that should be thought of. Patients may survive an operation, but at the ruinous cost of broken health and incurable constitutional derangement. These contingencies are referred to by Mr. MacCormac and Dr. Lucas-Champonnière, and were very emphatically dwelt on by Sir James Paget in the remarks he made during the debate at St. Thomas's Hospital. "I have," he said, "spoken only of the mortalities after operations; but a mere escape from death is not all we have to wish for. It is not enough that a patient should just escape with his life; it is desirable that he should not be in danger from fever or from erysipelas, or any other acute disease, nor yet from chronic pyæmia or long-continued suppuration, or any other malady introduced or aggravated by the operation. He should be cured with as little illness as possible, and with as little increase as possible of the tendencies to tuberculosis or any of the degeneration of internal organs which may be associated with the disease for which the operation is done." Now, it is in this direction that the advocates of antiseptic surgery will have to work. In future it will not be sufficient to give the mortality returns alone, but also to record the temperature, the rate of repair, the presence or absence of suppuration, of traumatic fever, of septicæmia and of other wound-accidents, and the duration of treatment. In this way shall we best appreciate the alleged advantages of the antiseptic system. The teachings of modern pathology all point in this direction. They not only controvert the old notion that suppuration is a harmless and even a beneficial process, but favour the opinion that in any degree pus formation is a possible source of constitutional infection, which may manifest itself as septicæmia, pyæmia, tuberculosis, or by degenerations in the internal viscera. The ideal aim of the surgeon must more than ever be to get wounds to heal quickly, for then, as a rule, they will also heal safely and pleasantly. The advocates of the antiseptic system aver this can only be done by practising the antiseptic method. Those who are not already familiar with the details of Mr. Lister's method cannot have a better guide than one, or both of the works mentioned above.

An Elementary Text-book of Botany. Translated from the German of D. K. PRANTL. The Translation revised by S. H. VINES, M.A., D.Sc., F.L.S. London: W. Swan Sonnenschein and Allen. 1880.

ALTHOUGH the condensed style in which this book is written makes it to teem with facts and scientific phraseology, and deprives it of a strictly "elementary" character, yet there is no doubt that it will be read and appreciated by many students of the subject. The book was written—the preface tells us—to meet the demand for a less extensive work than that of Professor Sachs, but based upon the same

plan; and it has already passed through three German editions. The author plunges at once into his subject by dealing in the opening pages with the rather intricate matter of phyllotaxis and other points in morphology. Then follow sections on the anatomy and physiology of plants, which are written plainly, and serve to bring into prominence this interesting but still incomplete department of botanical study. The fourth part is that of classification—the Cryptogams are split up into three groups, the Thallophyta, Muscineæ, and Pteridophyta; and considerable attention is paid to the description of their characters. Then come the Phanerogams, which are arranged on a somewhat different plan from that most familiar to us in this country. In an appendix the relation between the English classification and that adopted in this work is given. It is in this part, indeed, that the reader will find himself most in difficulty, owing to these technological differences and to the extremely condensed form in which the characters of the plants are described. The book is copiously illustrated, and has been rendered into readable English. It is not by any means the first German text-book on this science that has been translated into our tongue; and in its severely scientific construction it appears less attractive to the English student than works of some of our own authors. Although there is a copious index, there can be no doubt that an equally careful glossary would add to the value of the book.

The Watering-places and Mineral Springs of Germany, Austria, and Switzerland. A Popular Medical Guide. By EDWARD GUTTMANN, M.D. London: Sampson Low and Co. 1880.

THIS is, as it professes to be, an essentially popular book, and is intended for the general and not for the medical public, although many members of our profession will, doubtless, be thankful for a guide like that which Dr. Guttman has produced, and which furnishes the reader with many common facts it is essential to know. The work is divided into four parts. The first furnishes those general considerations concerning travelling, diet, climate, and bath life which must be taken into account by all who intend trying the effect of balneo-therapeusis. The second part is devoted to a topographical review of the watering-places, and gives information of a kind which one finds in Murray's, Baedeker's, and similar handbooks; while the third and fourth parts review the subject from the point of view of the chemical composition of the waters and their various applications, and the particular applicability of special climates to special cases. The work seems to be comprehensive and accurate in the main; but we notice on glancing through it that the picture of Ems does not represent the Ems of the present day, but the Ems of a century since probably; that the map gives a very imperfect notion of the railway lines, especially in the Black Forest; and we have looked in vain in the index for any notice of Rippoldsau and the baths adjacent to it, or of Niederbronn or any other watering-place in the Vosges mountains.

New Inventions.

CALVERT'S CARBOLIC-ACID FUMIGATOR.

MESSRS. CALVERT have sent us a capital, handy apparatus for diffusing carbolic acid in a state of vapour. It consists of a strong cast-iron stand to hold a heater. Above this is fixed an iron cylinder perforated at the sides, and having at the top a cup-shaped cavity with a small perforation at the bottom. Into this cavity is poured carbolic acid mixed with water, in the proportion of two parts of the acid with one of water; and this, trickling down upon the heater within, previously made red hot, is rapidly converted into

and diffused as vapour. An iron hook is attached to the apparatus, to aid in the easy manipulation of the several parts. The apparatus is very compact and convenient of carriage, and is especially fitted for the work of an inspector of nuisances who may have to use carbolic-acid vapour for disinfecting purposes.

A FLUSHING-PAIL.

MR. W. BENNET sends us for examination two tin pails: one to contain water for domestic use; the other to be used solely for water intended for hand-flushing a watercloset. The larger pail is a well-made article with cover, and will hold two gallons. The smaller pail will contain a gallon, and it differs from ordinary pails in having an obliquely placed perforated diaphragm within it. When the contents of the pail are cast into a watercloset, the water within the part partially cut off by the diaphragm passes out less rapidly than the greater bulk of liquid in the other part of the pail, and serves, in Mr. Bennet's estimate, to secure the trap of the closet-pan being duly charged after the flushing. Mr. Bennet has distributed a considerable number of these cans among the tenants of houses in Liverpool courts. He seems of opinion that the flushing-can will render unnecessary the attaching of flushing apparatus or special cisterns to waterclosets, or the ventilation of soil-pipes when connected with the simplest form of watercloset. In both these matters his observations run counter to experience.

The Lancet Commission ON THE MEDICAL USE OF WINES.

II. WHITE BURGUNDY WINES.

IN our previous issue we pointed out that white Bordeaux wines are but little known and appreciated in this country, although the red kinds are freely prescribed and consumed. White Burgundies are even less known than white clarets, and, with the exception of those classed under the name of "Chablis," are rarely seen except in some foreign restaurant, and even then are seldom tasted by the English consumer, although he may be fairly well acquainted with the red Burgundies, such as Beaune, Chambertin, Pommard, Nuits, &c., and perhaps have heard of the Clos de Vougeot or La Romanée Conti. It is a question of some interest, why the white wines, which are frequently superior in true vinous flavour, mellowness, and fragrance, and more stimulating in proportion to their contained alcohol, are thus neglected for red wines of the same locality and vintage. Is it because that, as a rule, the cheaper white French wines are less astringent and somewhat thinner than the corresponding red wines, and that the more expensive and full-bodied ones are certainly sweeter than the English palate is accustomed to? Moreover, dyspeptics, with a tendency to acid fermentations, can undoubtedly take many red wines with some freedom and occasionally with advantage; and this they can rarely do in the case of most white French wines. The older and well-matured wines are, as a rule, too sweet, and the thinner ones are very apt to cause, or at any rate aggravate, those forms of indigestion which give rise to acidity, heartburn, &c.

The best white Burgundies imported into England are the Montrachet and Meursault wines, and they are remarkably improved by keeping for some years. The best vintages now obtainable are those of 1865 and 1870, and although their alcoholic strength is much less than the crude fortified ports and sherries so freely prescribed, they are vastly superior in most cases in which stimulants should be ordered. White wines of the adjacent districts are generally classed as Burgundies, and are labeled Chablis, Pouilly or Rully, if not even Meursault or Montrachet. Most of the white wine from this neighbourhood passes under the

generic name of Chablis, although true Chablis, we are told, but rarely comes into this country, and as specimens vary even more than white clarets, great caution must be exercised in recommending their use.

Specimens of very good Chablis have been submitted to us [Coindreau, Dotesio, Fearon and Sons], all at an average price of 30s. per dozen, and we analysed one of them with the following results:—

	(E.)	In 100 vols.
Total solids ...	...	1.89
Grape sugar ...	...	.05
Fixed acid ...	...	.61
Volatile acid ...	...	.13
Absolute alcohol	{ by weight ...	8.86
	{ by volume ...	11.00

If we compare this with the analysis of the cheaper white Bordeaux wines, we find a slight increase in the fixed acid, but there is somewhat less alcohol and total solids, with a marked decrease in the percentage of grape sugar. Clinically speaking, these wines are more stimulating, although they contain a little less alcohol; they are slightly more acid, but their special importance is the almost complete absence of any unfermented sugar. We should not recommend them as general tonics, or as refrigerants, unless very largely diluted, and we should hesitate to order them for a dyspeptic patient, or one who was liable to or had suffered from gout. A diabetic could take them if diluted as a beverage for assuaging thirst, or undiluted as a dinner-wine, with even more impunity than most white clarets. Like the latter, they have a slightly aperient rather than a constipating effect, and this must be remembered if they are ordered for delicate invalids with any tendency to diarrhoea. For general medicinal purposes, as tonics and aids to digestion, we should choose the cheaper white clarets in preference to the ordinary specimens of Chablis, although the latter are much fuller in flavour, mellow, and more exciting.

A wine marked Meursault, at 54s. per dozen [Dotesio], of delicate flavour and more body, contained a slightly larger percentage of alcohol and less fixed acid, but otherwise on analysis differed but very little from the preceding.

Grape sugar ...	...	.08
Fixed acid ...	...	.48
Volatile acid ...	...	.13
Absolute alcohol	{ by weight ...	10.77
	{ by volume ...	13.34

As an example of the most expensive white Burgundies we selected for analysis a specimen of Montrachet, 1870 vintage, at 80s. per dozen [Pfungst and Co.] It had great body, a pure mellow flavour, and a delicious fragrance, and was as choice a wine as could be desired by anyone.

	(G.)	In 100 vols.
Total solids ...	...	1.99
Grape sugar ...	...	.31
Fixed acid ...	...	.46
Volatile acid ...	...	.12
Absolute alcohol	{ by weight ...	12.08
	{ by volume ...	14.93

Except in the slight increase in alcohol and a decidedly larger (four times as much) percentage of sugar, there is but little difference between this and the former specimen, although in every respect it was a far superior wine. We must again insist, therefore, on the obvious fact that chemical analysis cannot give more than a few crude results to guide us in our choice of wines for clinical purposes. Although containing much less sugar than the old Sauterne of the same vintage (*vide* analysis C in previous number), a diabetic should also avoid such a wine as the above. But for a primarily stimulating and afterwards slightly sedative effect, an old Montrachet can be placed side by side with the best Sauternes, even the famous Château d'Yquem.

Another specimen of Montrachet, 1876 vintage, at 30s. per dozen [Barnard and Co.], was a remarkably delicate and sound wine, and shows that good white Burgundies can be procured by the invalid at even a less price than fortified wines of any reasonable degree of maturity. The advantage of such a restorative as a good Burgundy wine, in which the alcohol is less than 15 per cent. by volume, must be so obvious to every practitioner who has to deal with tardy convalescence after fevers, operations, &c., that we can only express our surprise that these valuable wines are so seldom prescribed.

THE LANCET.

LONDON: SATURDAY, JULY 3, 1880.

THE General Medical Council will meet next Wednesday at 2 o'clock. We should be disposed to prognosticate that the meeting will not be a very long or important one. It is, of course, never possible to say how long a very unimportant subject may occupy the Council. Occasionally it seems to spend more time over trifling matters than over serious ones. But, all things considered, we should not expect the meeting to occupy more than two or three days. There is really an absence of any great work to be done. The time of meeting must be highly inconvenient to some members, especially those connected with the Scotch universities. The change of Parliament, interrupting the inquiry by a Select Committee, and the determination of the Government to take the interval of the session to consider the subject of medical legislation, have a paralysing effect on the Council and the Corporations as regards any active work, and will dispose them to do nothing but what is urgently in the way of their duty. Under these circumstances we may suppose that the Council will not have a long sitting.

It is probable that amongst the few questions of interest which it will be called on to consider, one will be that of the Dentists Act, and the question of repeal or amendment in it. It is well known that the Council has been memorialised on this subject by two different bodies in favour of two very different courses, fulfilling our anticipations that the Council will find itself hindered in its general work by reason of its duties under the Dentists Act. Nothing is more certain than that the Dentists Act has given great dissatisfaction to the profession, and to most of those members of the dental specialty who have had a professional education and who hold full professional qualifications. The admission to the dental register of thousands of persons destitute of all previous professional status must have surprised them as much as it has grieved those who by very different ways have attained to medical registration. The grievance of the latter is not less because the Medical Council and the medical corporations gave their sanction to the Dentists Act, and are placed at a great disadvantage now in asking either for its repeal or its material amendment. At its approaching meeting the Council will have to consider a memorial from the Association of Surgeons Practising Dental Surgery, asking for the amendment or the repeal of the Dentists Act of 1878. They complain that whereas the Act was intended to make provision for the registration of surgeons "specially qualified to practise as dentists," and the highest estimate of the number of those so qualified was not more than 2000, more than 5000 persons have been so registered. In consequence of the want of interpretation of the terms dentistry and dental surgery, each person claiming registration has interpreted these words according to his own wish and fashion, and so many persons have been placed on the Dentists' Register without any claim to be considered "specially

qualified." The Association of Surgeons Practising Dentistry sees no chance of the Medical Council acting efficiently in the removal of names improperly registered until the words "specially qualified" are clearly interpreted. And they maintain that the Medical Council, "a large and important body, meeting at rare intervals," is not the body best fitted to administer the Dentists Act.

But the Medical Council will have another memorial from the Representative Board of the British Dental Association, expressing ample satisfaction with the Dentists Act and the Medical Council, and the gratified feelings with which the dentists find themselves registered under the auspices of the Council, and reminding the Council, very naturally, of their general approval of the Dentists Bill. It is most desirable that whenever medical legislation takes place opportunity should be taken to define what dentistry is, and to confine persons not surgeons to the use of such titles as will not mislead the public—titles in which dentistry shall appear as the principal calling, and not surgery, as many of the recently-registered dentists would imply by their way of putting their titles. The Medical Council is bound to abate, as far as its influence goes, the harm done by the admission of unfit persons to the Dental Register. One or two cases of application to be registered in the Medical Register on curious grounds have been referred to the General Council by the Executive Committee.

One other subject, almost an annual, will perhaps claim a little of the Council's attention—namely, the question in dispute between it and the Irish Branch Council as to the proper mode of procedure in cases where alterations in, or additions to, the Register have to be made. But the question seems pretty nearly settled in favour of the views of the Irish Branch.

One thing the Council ought to do, and that is not to separate without agreeing to urge on the new Government the critical situation in which all medical bodies are placed by the late dissolution of Parliament, just when a Select Committee was engaged in investigating the changes necessary in the Medical Acts. In the absence of other business that can long occupy its time, the Council cannot better spend an hour or two than in formulating such a representation, and in making the Government understand that there can be no satisfactory action on the part either of the Council or of the corporations, until they are put into a more assured position, and one more consistent with the interests of the public and the profession than the present.

THE Bill brought into the House of Commons by Mr. DILLWYN to amend the laws relating to lunatics foreshadows the course which legislation must take if we are to escape from the difficulties which surround the existing laws and practices as to the care and management of lunatics. The provisions of the Bill manifest an accurate appreciation of the cardinal defects of our present system of lunacy administration, and, which is of not less importance, show that its promoters have rightly, as we think, apprehended the principles upon which measures directed to their removal must be based. Briefly, the Bill provides for the initiation of a plan for the gradual acquisition by the public of private asylums, and the placing of these institutions on a public footing; also, for the more assured development of the

functions of these asylums as *hospitals*—in other words, as places for the medical treatment and cure of lunacy as contrasted with their function as *retreats*—that is to say, as places where the safety of the lunatic is alone in question.

So far as the first principal object is concerned, it is idle to blink the fact that until private asylums cease to exist we cannot hope for a healthier state of feeling among the public as to the treatment of lunatics in asylums than now prevails. It matters less that this feeling is chiefly an affair of sentiment than that it exists, and, on the one hand, interposes a formidable obstacle to the just curative treatment of lunacy; and, on the other hand, is apt to manifest itself in fashions most injurious to the credit and dignity of the profession, and to the true welfare of the lunatic. The influence of this state of feeling has been unfortunate in every way by subordinating the true curative treatment of lunacy to secondary conditions affecting the restraint of the lunatic. It underlies in our public asylums that tendency to the grandiose architectonic provision for, and histrionic management of, the lunatic which stands for treatment in the minds of perhaps the greater number of the persons who take an interest in these portentous establishments; while in the private asylums it is contented with certain prettinesses of arrangement quite irrespective of the curative object which should be had in view. In both cases the lunatic is the ultimate sufferer, and in relations to the private asylum public feeling often brings about the very thing which it would obviate—namely, the prolonged detention of the patient.

Up to the present moment the private asylum has seemed a necessity, if the exigencies of lunacy among all classes of the population were to be duly met; and this form of institution has given, and still gives, occasion for the display of talents which have ranked their possessors (for example, CHARLTON, TUKE, CONOLLY, the FOXES, and others, too many to mention) among the most honoured names in medicine and in the list of benefactors of the human race. But not even these names have availed to disabuse the public mind of the suspicions that attach to institutions which in reality are commercial undertakings specially privileged by law to infringe the liberty of the subject, as no other private enterprise is permitted to infringe it, and which in too many instances are valuable properties, the medical element being superadded and subordinate. The time has come when public opinion may be prepared to solve this question in the only way in which, we believe, it admits of a satisfactory solution—namely, by supporting Parliament in a course of procedure which would enable defined public authorities to acquire private asylums by purchase and convert them into public institutions. One way in which this may be done is set forth in detail in the Bill. Mr. DILLWYN would authorise justices of counties and boroughs to raise money or issue bonds on terminable annuities for the purchase of private asylums, or the construction of new establishments by which these may be replaced. Whether a proposition of this sort, involving consequences of such magnitude, should not emanate from the Government rather than a private member, we do not propose to discuss here.

So far as the second principal object of the Bill—namely, the development of the curative functions of the asylums as contrasted with their seclusionary functions—is

concerned, the provisions are of great moment, and, we apprehend, open to few objections. They would provide for a check upon the issue of certificates of lunacy and the admission of patients to an asylum in a way which would seem to obviate all danger of the issue of improper certificates, while at the same time facilitating the early treatment of the mentally afflicted. To these ends the appointment of a "Medical Visitor" would be continued, but medical superintendents, honorary or salaried officers of any hospital for nervous diseases, or of an asylum in the district to which the Visitor may be appointed, or medical men engaged in private practice would be debarred from holding the appointment; while medical coroners, medical officers of health, and qualified professors or teachers of a medical or scientific subject in any university, college, or medical school would be eligible for it. The Medical Visitor would have the duty of visiting and examining all patients immediately after their admission into an asylum, and of doing other acts, in view of the interests of the public and patients, in relation to admissions and discharges. With the object of promoting the more ready and earlier entrance of patients into asylums, and facilitating curative treatment, it is proposed to make provision for the issue of emergency certificates, signed by a single medical man, and which shall have force for only forty-eight hours, unless countersigned in the interval by the Medical Visitor after an examination of the patient. Other provisions relate to the more effectual supervision of asylums, and the voluntary seclusion of the insane; and all show an intelligent regard for the protection of the patient from improper confinement, while tending to develop the more truly curative element of asylum treatment, and to relieve the sufferers with mental disease from the stigma which the law now casts upon them.

THE announcement which we made last week, that the Governors of St. Thomas's Hospital had passed the scheme approved by the Charity Commissioners for the admission of paying patients into the hospital will seem at first sight an unimportant matter; most people will regard it as merely a step in the carrying out of an already determined and approved course. We have heard so much of the proposal to convert one block of the hospital into a separate hospital or home for remunerative paying patients, and the arguments for and against the scheme have been so fully discussed, that it was hardly expected that under cover of this scheme great and radical changes were to be introduced into the hospital itself. Some two years ago, when first the proposition of admitting paying patients was mooted, strong opposition was raised by the medical staff and by the profession at large against a plan which would impose additional unpaid labour upon the staff, and might place them in an invidious position as regards their professional brethren. The plan was, it was understood, abandoned; and a separate Home Hospital, independent of the control or services of the staff, was decided upon, concerning the details of which the medical officers were understood to have given some counsel.

It is almost incredible, we say, that, after such a conflict and decision, the treasurer and governors should have come to such conclusions as are now made public. In saying this, we do not for the moment raise the question whether the

proposed scheme is right or wrong, beneficial to the hospital or the reverse; this may be considered later. The scheme as approved by the Charity Commissioners is divided into two separate branches: first, the establishment and regulation of a hospital for remunerative paying patients, to be called the St. Thomas's Home, which is to be conducted entirely apart from the medical and surgical staff; and, secondly, the admission into the general wards of "poor paying patients," who shall pay only so much as will cover the cost of their maintenance. It is to the latter subject that we now draw attention. The scheme runs as follows:—

"1. That as many patients as could be contained in the remaining two wards of Block No. 2 (that is to say, fifty-two) shall, upon their agreeing to pay the actual cost incident to their reception and treatment, be received as vacancies occur into eleven of the general or ordinary wards of the hospital in equal numbers, and so that not more than five patients shall be in any one of such wards at the same time. 2. *That the provisions, with regard to applications for admission of poor paying patients into the hospital, and to the determination of each patient's term in the hospital, shall be the same as those hereinbefore contained concerning remunerative paying patients.*" 3. The charge to be three shillings a day. 4. Payments to be weekly and in advance. "5. Poor paying patients admitted into the hospital under the present scheme will be treated in exactly the same way as the ordinary patients for the time being are treated, and must in all respects conform to the regulations from time to time prescribed by the treasurer and house committee for the due government and management of the hospital. The payments, to be made as aforesaid, will entitle them to their board, medicine, and medical and surgical attendance and appliances, and to be nursed and attended by the nursing staff of the hospital."

It must be observed that in this scheme there are two important points wherein the condition of these patients will differ from that of the ordinary patients, quite apart from the fact of payment. The provisions for admission of remunerative paying patients, referred to in the second clause, are to the effect that all applications are to be made to the treasurer and house committee, or in cases of emergency to the treasurer alone; and that they have an absolute discretion in the matter. They are not to be admitted by the resident medical officer, who is usually responsible for the admission of suitable cases. Nor is the physician or surgeon in charge of the ward to judge either of the suitability of the case or of the time of discharge, as is always the case in well-regulated hospitals, and, we believe, in St. Thomas's. In other words, one out of about every five patients (we judge from the statistics) shall be selected by the treasurer on the ground of his ability to pay a guinea a week, and shall be removable only at his pleasure, the physician and surgeon having no option as to his admission or discharge, and the patient claiming medical and surgical attendance as being "entitled to it." In what position does this leave the physicians and surgeons? As the scheme stands no increase in the number of beds occupied is proposed; so that each one must submit to have five of his beds, at present occupied by cases of urgency or interest, taken up by guinea patients. In the case of the smaller wards devoted to special diseases, the proportion of such patients will be much larger than in the general wards. Into these wards, we apprehend, the cases most urgently needing special treatment or operation, selected from the out-patient practice, are admitted. In what position will the obstetric

physician or ophthalmic surgeon be if he is compelled to forego his right of admission to one-half or one-third of his beds? Many other objections might be urged, but the point on which we desire to dwell is that these changes have apparently been introduced without the consent of the staff, and are very different from those sanctioned by previous engagements. It is true that the treasurer stated, in a general way, that the senior physician and senior surgeon had expressed approval of the scheme. But we have no evidence either that the entire scheme was submitted to them, or that they were authorised to speak or act for the remainder of the twenty or more members of the staff, upon whom the whole matter must have come as a surprise. It is not probable that the staff would quietly eat their own words, or go back from their carefully considered and recorded resolutions. Their existence and rights are practically ignored in the report. It may, perhaps, not yet be too late to amend the scheme in such a way as to clash least with the interests of the staff and of the profession generally. It would be a very different matter if patients were admitted in the ordinary way, and provision made for the levying of a suitable payment from those capable of affording it. Such a plan would be far less open to abuse, and would not trench on the rights of the staff or of the patients. We have no doubt that there are now many patients admitted in the ordinary way, and on proper grounds, who could well afford to pay for their board and medicine, and even something for lodging, and it would be no injustice to them, or to the medical attendant to accept or even to enforce such payment after proper inquiry. Many would probably be only too glad to make the return to the hospital for the services rendered. But a rate of three shillings a day for board, medicine, *medical and surgical attendance*, and nursing, does not sound well, to say the least. If the present plan is enforced, difficulties will spring up on every side. We can hardly suppose that the staff will tamely submit to a change which, in the mode of its introduction, is a grave affront to them as a body, and in its substance injurious to their interests. However cogent the reasons for its adoption, they may well complain that they are fully capable of appreciating and yielding to them if necessity urges; but "upon compulsion, no," must be their motto if they would retain their self-respect. If they have changed front and rescinded their former resolutions, they owe it to themselves and to the profession publicly to state the grounds upon which they have so done.

What is the position of the question as regards the patients and the poor generally? Much has been said of the necessity for increasing the accommodation for really needy and poor patients. And this is how it is to be done: by taking away fifty-two beds now actually occupied by the really poor, for those nominally poor who can pay a guinea a week, and choose to do so. This is to last until such time as a sufficient profit has been realised by the "remunerative" patients as to enable the governors to open two new wards. This may be by the year 1900, if the estimated and somewhat chimerical profits are to any extent realised, which would much surprise us. We doubt, indeed, whether in the first five years the expenses, together with a fair rate of interest on the initial expenditure, will be paid. If it be so nominally, it will be only by taxing the general resources

of the hospital for things not entered in the nominal expenditure. Space forbids our entering into the financial details, but they are an amusing as well as instructive study. It appears that it is possible to board "remunerative paying patients" at £6 a year less per head than nurses and wardmaids. This looks like profit, at any rate. We could wish that the governors had had the wisdom to try the humbler and more justifiable plan of taking moderate payment from those able to afford it, without embarking upon an expensive and hazardous experiment, which will severely strain the relations of the hospital to the profession and the public, and place themselves in a position from which it may be difficult to withdraw.

THE question of Hospital Registration raised by a correspondent in another part of our present number is one of considerable importance. It is not the first time that attention has been directed to the prevailing diversity in methods of hospital registration, and the experience of the Pathological Society's committee, quoted by our correspondent, is by no means an isolated instance of the difficulty, or almost the impossibility, of obtaining parallel information on special points of observation in the records of the registrars of different hospitals. It must be borne in mind that the general adoption of a system of registration by the metropolitan hospitals is a comparatively recent event. There are few hospitals which have pursued the present plan of registration for twenty years. Then not only do the methods followed differ almost at every hospital, but it happens that even at the same institution the registration may vary much in scope and quality, almost from year to year. Such changes are a necessary consequence of the brief tenure of office of a hospital registrar, for in the absence of any well-defined plan it often happens that an incoming registrar desires to "improve" on his predecessor's method. This is seen in the increasing elaboration of reports which are published annually by many hospitals. No better illustration of the lack of uniform registration at the different hospitals could be given than these reports afford. The advantages of uniformity have often been insisted on, not only in the plan of drawing up reports, but in the manner in which the registration is itself carried on. The question arises whether it be possible to take steps to ensure such uniformity, and in what manner it could be enforced. Were our hospitals under the guidance of some central authority, were they controlled by the State or the municipality, it would be an easy if not a necessary measure to ensure a perfect system of registration. But at present these institutions go each their own way in the management of their affairs, and are as independent of each other in the manner in which they compile statistics as they are in their modes of admitting patients or of nursing them. So, then, there seems no better way than that suggested by Mr. HOWLETT, which we commend to the attention of all present and past hospital registrars, and by means of a Hospital Registration Committee, a sufficiently comprehensive scheme might be drawn up for general adoption. We believe this would do good in more ways than one. It would tend to bring into closer relations institutions that work for the same ends; it would facilitate the labours of

those who are in search of information upon special points, and this would be a distinct gain to medical science. We might also then look for the annual publication of a series of reports which would be drawn up on the same lines and do credit to our metropolis. Still we must recognise the existence of several difficulties in the way of initiating and carrying out such a scheme. It would require many concessions to be made on the part of each hospital, which naturally deems its own plan the best. But there is no reason why the scheme should not be set on foot, seeing how great are the advantages that may be expected to accrue from it.

Annotations.

"No quid nimis."

THE COLLEGE ELECTION.

THE annual election of members of the Council of the Royal College of Surgeons took place on Thursday, the 1st inst. As we have previously announced, the vacancies were caused by the death of Mr. Hancock, the retirement by rotation of Messrs. Busk and Curling, and the resignation of Mr. Simon. The candidates in the order of seniority are: Mr. William Cadge, of Norwich; Mr. William Adams; Mr. Joseph Lister, F.R.S.; Mr. Thos. Bryant; Mr. Sydney Jones; Mr. J. Whitaker Hulke, F.R.S.; Mr. Thos. Smith; and Mr. M. Berkeley Hill. Voting began at two o'clock, and continued till five. The results were:—

Mr. CADGE ...	...	...	174,	plumpers	14
Mr. BRYANT ...	...	...	170	"	15
Mr. LISTER ...	...	...	169	"	1
Mr. T. SMITH ...	...	...	136	"	13
Mr. Hulke ...	...	...	107	"	6
Mr. Adams ...	...	...	87	"	6
Mr. Hill ...	...	...	51	"	6
Mr. S. Jones ...	...	...	45	"	4

As we explained last week, Mr. Simon's term of office would not, under ordinary circumstances, have expired until the year 1884. Section 14 of the Charter, 7th Vict., provides that whenever a vacancy occurs in any other way than by the retirement by rotation of a member of the Council, the Fellow elected as the substitute member shall hold office until the person in whose room he is chosen would have been liable to go out of office. Mr. T. Smith, having been elected by the smallest number of votes, is, in accordance with the bye-laws, the substitute member for Mr. Simon, and will accordingly have to retire by rotation in 1884.

In the evening the Fellows dined at the Albion Tavern, Sir James Paget, Bart., taking the chair.

INCURABLE DISEASE.

MALADIES which cannot be "cured" are the opprobria of medicine as an art, and, for the most part, they are not less the enigmas of medicine as a science. It should not, however, be hastily assumed that cases which cannot be cured must therefore be regarded as beyond the hope of recovery. There is a wondrous power of *self-cure* in the organism, and many a sufferer condemned by the "Faculty" has been relieved by Nature. It is most desirable that this should be borne in mind, for two principal reasons: first, because hope is itself a great specific, even for diseases which seem to be beyond the reach of any remedy, and nothing so greatly tends to destroy the natural chances of recovery as the depression produced by an adverse prognosis, which is often amusingly falsified by the facts of experience: second, it is

a most irrational position to take up that *any* malady is incurable. How can the scientist possibly feel sure of the proposition on which he erects his postulate? If it be generally difficult to prove a negative, it is absolutely impossible to do so when that negative is one that excludes the possibility of recovery from a disease. If the practical physician assumes that a case is incurable, he shuts himself out from the field of inquiry and experiment, where a remedy may be found. We are led to make these remarks by signal proof of the *impolicy*—to take no higher ground—of the position we condemn. Patients who are said to be suffering from incurable maladies go to adventurous practitioners, who try empirical remedies, or to “quacks,” and recover after they have been “given up.” The results of this procedure are to be traced in the advertisement columns of the lay newspapers, in which “cures” for incurable diseases abound; and it is absurd to suppose that no good follows their use. The *post hoc* is not the *propter hoc*, but that counts for nothing, to the public, to the physician who has “waited on events” while he tried his method, or to the quack who reaps the credit of a success he has neither earned nor deserved. These persons do not cure the cases they claim to have benefited, but the cases do get well. And the *modus operandi* is this: A distinguished and able practitioner makes a diagnosis or gives a prognosis which sounds like a death-knell. The patient and his friends are disheartened, and for the time hopeless. By and by hope revives, and in the moment of its rekindling, or after several successive collapses and recoveries of the spirits, the patient falls under the care of some one who, honestly or dishonestly, with or without knowledge, professes to be able to “cure” the case. It is true, perhaps—though even the most expert clinicians may be occasionally mistaken—that the disease is incurable, but the case may nevertheless “recover;” and it does recover under the stimulus of hope and perhaps good regimen. Contempt is poured on science, and quackery or empiricism triumphs. The issue is most satisfactory to the patient, but not so to the medical man. The moral of the tale does not need to be pointed. It lies on the surface. The category of “incurable” diseases should be reduced, and no case ought to be “given up” or condemned; for while there is life there is hope, and hope itself may, and does, cure even diseases which Science, in its supposed omniscience, asserts to be incurable, the physician being fooled.

THE HUNTERIAN MUSEUM.

IN his interesting annual report on the state of the collection under his care Professor Flower states that the total number of specimens added to the Pathological Department since his last report amounted to sixty-five, among which are many valuable preparations contributed by the medical officers of the Samaritan Free Hospital. There is also a curious illustration of recovery from severe injury in the skeleton of a beluga or white whale (*Delphinapterus leucas*), which had suffered from complete lateral dislocation of the atlas from the occipital condyles, many years before death, resulting in bony union in this abnormal position, with consequent very great contraction of the spinal canal. The animal (one of great rarity in the British seas) was taken near Dunrobin Castle, Sutherlandshire, in June last year, and its skeleton was sent to London for the purpose of preservation for the museum attached to the Castle; but when the condition of the bones of the cervical region was discovered, the Duke of Sutherland very generously relinquished his intention of keeping it, and presented it to the museum, as the most suitable locality for the remarkable and perhaps unique specimen.

The collection of specimens of Comparative Anatomy has received an important addition in a series of brains of various kinds of mammals and birds, seventy-five in number,

presented by the Zoological Society through the assistance of the late Professor Garrod, F.R.S. Some beautiful demonstrations of the anatomy of the horse's foot by means of sections have also been added. The series of preparations illustrating human anatomy, both by means of mounted dissections and transverse frozen sections, has been continued, and several additions have been made to the series of bones marked to show the spaces occupied by the attachment of the muscles, contributed by Mr. S. G. Shattock, Curator of the Museum of University College.

The very large male specimen of the giant salamander (*Sieboldia maxima*) from Japan, upwards of four feet in length, which had been kept for many years in the Gardens of the Zoological Society, having died during the last winter, was secured for the Museum by purchase, as previously no portion of this interesting form of animal was contained in the collection. The skeleton, a considerable part of which is cartilaginous, and would therefore have been lost if dried in the usual way, has been carefully prepared as a spirit specimen, and all the viscera have been dissected and mounted.

In the Osteological Department the celebrated “Barnard Davis” collection appears, but as this has already been described in THE LANCET we proceed to another valuable addition to it, through the liberality of Mr. Luther Holden, President of the College. It is a collection of remains of natives of the islands of the Western Pacific, consisting of a complete skeleton of a man from Erromango, seven skulls from Ovalau, in the Fiji Islands, and eleven crania and heads preserved in a remarkable manner, hitherto quite unknown, from Mallicollo, a small island in the New Hebrides group. Forster, who accompanied Captain Cook in his visit to these islands in 1774, says: “In Mallicollo we observed that the greater part of the skulls of the inhabitants had a very singular conformation; for the forehead, from the beginning of the nose, together with the rest of the head, was much depressed and inclining backwards, which causes an appearance in the looks and countenances of the natives similar to those of monkeys.” These skulls fully confirm the accuracy of this description, and show that the peculiar conformation is evidently due to artificial compression in infancy, exactly according to the manner of the ancient Peruvians, which is the more singular as the practice is not known to exist in any other of the numerous islands of the Pacific.

Amongst other additions to the series of Human Osteology, Professor Flower specially calls attention to a very remarkable skull of a microcephalic idiot, the only example of the kind in the Museum, presented by Dr. John Shortt, Surgeon-Major in the Madras Army, who has also been at considerable trouble and expense in collecting a large series of crania of natives of Southern India, which were previously among the desiderata of the Museum. Four skulls of Zulus, obtained on the field of Isandhlwana, in December last, by Mr. H. F. Fynn, resident magistrate, and forwarded by Colonel C. B. H. Mitchell, Colonial Secretary at Natal, at the request of Dr. R. J. Mann, are of great interest; and it is to be hoped that they are only the precursors of a more extended series from the same part of the world, for collecting which the late military operations must have afforded considerable opportunities.

Amongst the donors are several members of the Council of the College and public institutions, as the Zoological Society, the Governors of St. Bartholomew's Hospital, &c. To the surgical instrument department, which was founded by the late Sir William Fergusson, Dr. Humphrys, F.R.C.S., has contributed the amputating case of the late Sir Astley Paston Cooper, Bart.; and Mr. R. Davy, F.R.C.S., a lever for compressing the common iliac artery per rectum; Mr. Andrew Maclure, a field tourniquet; and Mr. E. Davies, Laennec's stethoscope, &c.

THE DIAGNOSIS OF RABIES AND HYDROPHOBIA.

A CORRESPONDENT, Mr. Hopkin Davies, relates, in another column, the particulars of a case of hydrophobia which deserves attention on account of a singular diagnostic error on the part of a veterinary surgeon. Our readers will remember that a few weeks ago we mentioned the ravages committed by a dog, obviously rabid, at Taibach. The letter of Mr. Davies supplies some subsequent particulars. The dog, it seems, after having him shot, was buried; but the carcase was exhumed two days later, and an examination made by a local veterinary surgeon. The opinion said to have been given by him as to the nature of the disease from which the animal suffered is, we would fain hope, unique in the annals of veterinary practice. Some wool was found in the dog's stomach, and hence the dog was not rabid, but its conduct was amply accounted for by the uneasiness occasioned by the wool! Now, it is not always possible to say, from examination after death, whether a dog has or has not suffered from rabies. We say this advisedly, bearing in mind a case in which one of the most intelligent and experienced veterinary surgeons in England gave as his opinion, that a certain dog did not die from rabies, the characteristic appearances being absent, when the subsequent history of the outbreak made it certain that the disease was rabies. But if there is one morbid appearance thoroughly characteristic of the disease it is the occurrence of foreign bodies—wood, coal, wool, &c., in the stomach of the animal—objects on which it has exerted its propensity to bite. And this most characteristic evidence of rabies was, it is alleged, regarded as proof that the disease was not rabies at all. The symptoms, as we noted at the time, were characteristic, and the post-mortem appearances, so far as described, were characteristic also; and now we learn the sad corroborative proof in the occurrence of hydrophobia, in well-marked form, in one of the bitten persons, commencing on the twenty-first day, and running a rapidly fatal course. How forcibly do the subsequent particulars of this outbreak suggest the urgent need there is for the official diffusion of knowledge of the early symptoms of rabies, and, if we may trust the reports supplied to us, it appears also that such information would not be superfluous even to members of the veterinary profession.

THE SANITARY CONDITION OF DUBLIN.

THE long looked-for report of the Royal Commissioners appointed last September to inquire into the sewerage and drainage of Dublin, in so far as such affected the sanitary condition of that city, has at last appeared. The two Commissioners, Robert Rawlinson, Esq., C.B., C.E., and Dr. MacCabe, Inspector under the Local Government Board for Ireland, in their report, state that the house-drainage in Dublin is extremely defective, and that this is the case in all classes of houses; that the river Liffey is polluted from the inflow of sewage, especially during the periods of drought and warm weather; and that with the extension of the city and the completion of main-sewering the contamination will be greatly increased; while a fuller and more complete flushing of drains and sewers will also add to the impurity. In 1879 Dublin contained 24,840 houses, of which no less than 9760 were let in tenements, and of these 2400 were occupied by more than one family, and were in a condition which rendered them unfit for human habitation. To sum up, the Commissioners believe that the main sewers have been improved but not completed; that new sewers are required, and the entire system more fully ventilated; that house drains are very defective; that privy accommodation is generally bad throughout the

poor quarters of the city. They regard the tenement houses as the principal cause of the excessive high death-rate, being dilapidated, dirty, ill-ventilated, overcrowded; so that disease, a craving for stimulants, and extreme poverty are thereby fostered. Moreover, public scavenging is inadequately performed; there is no municipal system of private scavenging. There is also no adequate provision for baths and washhouses specially adapted and planned for the use and benefit of the working classes. They regard the Liffey as being polluted by the sewage of the city so as to be offensive, although apparently not directly injurious to the health of the inhabitants; so that they cannot hold it accountable for the high rate of mortality which has prevailed and continues to prevail within the districts which it traverses. The Commissioners, while regarding the improvement of the house-drainage of Dublin and of the tenement houses, better scavenging, and filth removal as matters urgently necessary in the interests of public health, are also of opinion that the sewage of the entire city and of its suburbs ought to be so disposed of as no longer to constitute a nuisance.

HOME HOSPITALS.

THE first of the hospitals founded under the auspices of the Home Hospital Association was formally opened on Monday last, the opening ceremony being performed by the Bishop of Winchester. The hospital, which is called Fitzroy House and is situated on the north side of Fitzroy-square, is well adapted for a trial of the objects which the Association have in view—that of providing first-class accommodation for those in good circumstances who require nursing. It may be questioned whether, in some respects, the Association have not aimed too high; the accommodation which is afforded suggesting wealth and luxury rather than modest competence as a condition of entry. Everything which could be done with the material at their command seems to have been done by the committee. The adaptation of a private house, however spacious and well-built, to hospital purposes is always a work of difficulty, and the success attained reflects credit on all concerned. The sanitary arrangements are very good, the drainage being especially well managed, and so constructed as entirely to obviate the danger of sewage poisoning. The possibility of ventilation of each room is very thorough, in some parts suggestive of treatment by hyper-ventilation, but as it is mainly by means of windows it is doubtful whether it will be capable of maintenance when the wards are in actual use. The total absence of bed-curtains, or of any provision for them, though in accordance with the best tenets of modern hygiene, may possibly not meet with the approval of the patients, when combined with ventilation through open windows. But in all other details the comfort as well as the health of the patients, and the cheerfulness of their surroundings, have been carefully studied.

But it must be pointed out that this is, after all, only a nursing home, not a hospital proper, and that in one respect there is a serious want, which will inevitably be felt in a large number of cases—the absence of any resident surgeon. No doubt the committee have carefully considered this point, and have concluded that the possible inconveniences might be greater than the probable benefit. But it is one of the great advantages of a hospital that there is always on the spot some one to be appealed to, and to act at once in cases of emergency; nor can this be met in the case of acute illness, or of fresh and unexpected symptoms, by calling in any neighbouring medical man who may chance to be at home. It is true that this state of affairs is what exists in private houses, but this sort of hospital should be prepared to admit cases of operation, for instance,

which require skilled assistance, and are rarely performed, or are treated at a great disadvantage, in private houses.

So far as it goes the institution deserves encouragement, and should the management be judicious it will, no doubt, be successful, and may be the precursor of other similar hospitals adapted for a somewhat less wealthy class of patients than those for whom the present one is designed.

FAINTING IN CHURCH.

It seems strange at first sight, but not at all wonderful when we come to look closely into the conditions and circumstances of the case, that fainting in church should be a frequent occurrence, and in some congregations even reach the proportions of an epidemic. There can be no question that the ventilation of many churches and places of worship, which are wont to be crowded, is radically defective, and the vitiated atmosphere inevitably affects the weakly as a powerful depressant. This is a matter which requires attention. Medical officers of districts might bring more influence to bear on churchwardens and the wardens of chapels, that measures may be taken to receive the ingress of pure air without draught and the escape of foul vapours. Meanwhile it cannot be doubted that there is room for a little serious argument on this subject, and ministers might do well to remonstrate from the pulpit with congregations in which the "habit" of fainting is prevalent. In some of the chapels attached to lunatic asylums there are special apartments for the accommodation of epileptics who have "fits." It would almost seem that in some churches and chapels there should be rooms set apart for the retirement of those who contemplate fainting.

THE NEW CARDIAC SEDATIVE.

THE interesting experiments of MM. Sée and Bochefontaine on the action of erythrophleine, to which we called attention last week, deserve a more detailed description. In 1876, MM. N. Gallois and E. Hardy discovered in the *Erythrophleum guineense*, a leguminous plant, an alkaloid, erythrophleine, which they found to possess poisonous properties, and a remarkable action on the heart. The latter suggested to MM. Sée and Bochefontaine the probability that this alkaloid might be found useful in cardiac diseases. They therefore instituted a series of preliminary investigations into its physiological action, and especially into those effects which could be recorded by the graphical method. They have communicated the results to the Académie de Médecine. They examined first its effects upon frogs, and subsequently those upon rabbits and dogs. The latter series are the most important. Hypodermic injection was chiefly employed. A centigramme, introduced beneath the skin of a dog, had no effect. Twice the quantity killed a large dog in two hours. They found that while one milligramme per kilogramme of body weight had no appreciable effect, a milligramme and a half was fatal in a few hours. The toxic power of erythrophleine appears thus to be about the same as that of Homolle's digitaline. The first sign of the toxic effect consists of restlessness, followed by a period of weakness, and this by vomiting or efforts at vomiting. The latter are the true initial symptoms of the toxic action, and, if the dose of the poison is not too great, they may cease. The animal then quickly returns to its normal condition. The circulatory apparatus is affected in a manner somewhat similar to the digestive. The intra-arterial pressure is increased, the pulse becomes irregular and then retarded. The retardation is characterised by the force of each pulsation, and by the uniformity of the intra-arterial pressure, which is not modified by the respiratory movements, as it is in the normal state. This period is followed by another, in which the pulse is extremely quick and feeble. The influence of the respiratory movements on the blood-pressure reappears,

the intra-arterial tension gradually lessens, the cardiac pulsations become weaker and weaker, and cease for a moment from time to time, and are at last permanently arrested. The respiratory movements seem to be directly influenced by the poison, as well as secondarily by the effect on the circulation. At first they are, as a rule, slightly slower and deeper than normal. When the heart's action is accelerated towards the end, the respirations are frequent and extremely energetic. In almost all the experiments the movements of respiration ceased at the same time as those of the heart, but in several cases the movements recommenced, and continued with energy for one or two minutes. The poison has a distinct action upon several parts of the nervous system. Thus faradisation of the peripheral portions of the pneumogastric nerves in the neck does not arrest the heart of an animal under the influence of erythrophleine as it does that of a healthy animal, and faradisation of the central extremities of these nerves does not accelerate the heart as it does in a healthy animal. Nevertheless, this procedure causes the same rise in pressure as under normal conditions. Immediately after death the heart is found in diastole, flaccid, but full of blood. Sometimes the ventricles present a tremulous movement similar to that which is seen after they have been faradised. Usually the heart has not lost its electrical contractility. The pneumogastric nerve retains its action on the stomach. The excitability of the phrenic nerves is, however, lessened or even lost, while that of the sciatic nerve, and of the sympathetic, is not diminished. We are promised some further observations on the therapeutic uses of the drug.

WEAK-BACKED CAB HORSES.

THE attention of the officers of the Society for the Prevention of Cruelty to Animals should be drawn to the number of weak-backed horses worked in the cabs which crowd the streets of London. In some cases there is reason to suspect the existence of disease, which may be accompanied by great pain. Several instances of a painful nature have been noticed within the last few days, in which the animal has with difficulty commanded the movements of its hinder limbs, and, though going fairly well, has strained severely at starting. Commonly, of course, difficulty in starting proceeds from other causes; but there seems reason to fear that in a considerable proportion of cases actual disease is overlooked. Considering the hard terms on which cab-drivers hire their horses, and the work they are compelled to do in order to earn a small pittance for their families, the stress of the law to put down this evil should be made to fall on the owners, and it would be well to inaugurate a systematic inspection of the stables at times when the horses are in, and when a visit from the inspectors is not anticipated! If the work is to be done at all, the Society must take it up; the officials appointed to discharge the duty do not seem to take any interest in the matter.

EPIDEMIOLOGY IN THE LABORATORY.

THE researches of Dr. Burdon-Sanderson, Mr. Duguid, and Dr. Greenfield on anthrax in this country, and of M. Pasteur on fowl-cholera, are apparently about to give us an insight into some of the more recondite problems of epidemiology, and to furnish us with clues to further research of the most hopeful nature in the practical as well as theoretical aspects of epidemic diseases. From the researches of the first-named gentleman we learn in what fashion a virulent disease by being passed through the bodies of another class of animals and subjected to certain processes of cultivation may be deprived of its virulence, and become in this milder form, when inoculated, protective against the more virulent forms of the same infection. We

learn also that the poison of anthrax may multiply indefinitely in certain media outside the body of an infected animal, and, so propagated, retain its properties for periods of years in a latent form, and regain its activity and pristine virulence when exposed to suitable conditions. Dr. Burdon-Sanderson's and Dr. Greenfield's papers on Anthrax in the last number of the *Journal of the Royal Agricultural Society* show how important are these researches in view of some of the greater questions of epidemiology. M. Pasteur's investigations regarding fowl-cholera lead to the same broad conclusions as the researches of the English investigators on anthrax, and we can well understand how, on the floor of the Academy of Medicine the other day, he, with the boldness of genius, expressed a hope that it would be possible to produce a variola of minimised power, the equivalent to vaccine lymph, in the physiological laboratory, and so release ourselves from dependence upon the passage of the virus through bovine animals for a protective lymph. It is in this direction, and not as concerns small-pox and the virulent maladies of animals alone, that these researches tend, and with most hopeful prospect.

"A BILL TO AMEND THE VACCINATION ACTS."

THE following is the text of the measure to which we referred last week :—

"Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :
1. This Act may be cited as 'The Vaccination Act, 1880.'
2. This Act shall be construed as one with the Vaccination Act of 1867, the Vaccination Act, 1871, the Vaccination Act, 1874, and those Acts and this Act may be cited together as 'The Vaccination Acts, 1867 to 1880.'
3. After the passing of this Act no parent of a child shall be liable to be convicted for neglecting to take or to cause to be taken such child to be vaccinated, or for disobedience to any order directing such child to be vaccinated, if either (a) he has been previously adjudged to pay the full penalty of twenty shillings for any of such offences with respect to such child ; or, (b) he has been previously twice adjudged to pay any penalty for any of such offences in respect of such child."

ROYAL UNIVERSITY OF IRELAND.

THE Senate of the newly-constituted University held its first meeting last week under the presidency of the Duke of Abercorn, Chancellor. In accordance with the charter, the Senate proceeded to elect a Vice-Chancellor from among their members, and Lord O'Hagan, Lord High Chancellor of Ireland, was appointed. A committee, consisting of twelve members, was then appointed to draw up a curriculum of examinations for the several Faculties, and a scheme of statutes, rules, and ordinances for the University ; also, a financial scheme for providing fellowships, scholarships, prizes, and the general maintenance of the University, and to determine on a site and suitable buildings.

THE THERMO-CAUTERY.

OUR Edinburgh correspondent writes : "Professor Spence observed lately, in speaking of the relative merits of the thermo-cautery and the knife in excision of the tongue, that the cautery was chiefly valuable in dividing the mucous membrane that stretched between the organ and the oral cavity, as thus much troublesome hæmorrhage might be avoided ; but that for all other stages of the operation the knife was probably more satisfactory. As regarded the means of gaining access to the tongue, one might either split the jaw or divide the cheek according to circumstances. Mr. Joseph Bell removed a tumour from the parotid region

which implicated the sheath of the carotids, using the thermo-cautery ; and among other operations we have had lithotomy, ovariectomy, and trephining for abscess in the head of the tibia."

GUY'S HOSPITAL.

AT the adjourned meeting of the Court of Governors, held at Guy's Hospital on Wednesday, the 30th ult., the matters in dispute between the medical staff and the Treasurer were referred for investigation and report to a special committee, consisting of the following gentlemen : Sir Thomas Acland, Sir Trevor Lawrence, Messrs. C. Barclay, R. Harvey, Samuel Hoare, and Shaw Stewart. We understand that the committee has at once commenced its sittings.

OPEN CARRIAGES FOR HIRE.

THIS is the season when invalids and children are especially likely to be benefited by drives in the open air. Close cabs and carriages are of no use for the purpose, and it is difficult to procure suitable vehicles from the livery stables. Why do not some of the more enterprising cabmasters send out a few of the class common at the sea side ? Surely these conveyances would find full employment around the Parks and in drives about the outskirts. It is strange that the experiment is not tried. The number of persons of limited means who desire open flies during the warm weather must be very considerable. This is a small matter that comes under the notice of general practitioners, particularly in the more populous districts, almost daily while the brief season of "summer in London" lasts.

MICROFILARIÆ.

AT the last ordinary meeting of the Quekett Microscopical Club fresh communications were received and read from Dr. Manson, of Amoy, confirming and extending his researches respecting the nematoid hæmatozoa of man. New species of filariæ infesting the heart and bloodvessels of birds were also described ; likewise a new species of fluke, found by Dr. Ringer in the lungs of a Portuguese. In Dr. Manson's opinion this parasite, also encountered by him, is not an unfrequent cause of hæmoptysis in the Chinese. It has been named *Distoma Ringeri*.

A SPECIAL meeting of the Listowel Dispensary Committee was held last week at the request of the Local Government Board for Ireland, for the purpose of obtaining their views on the evidence given at the recent sworn inquiry into the charges preferred against Dr. Fitzmaurice, medical officer of the district, and of eliciting an opinion as to the manner in which he had discharged his duties generally during his term in office. After reading over the evidence, the Committee did not consider the charges proved, and unanimously gave their opinion to that effect. The Local Government Board have since exonerated Dr. Fitzmaurice from all the accusations made against him.

ON June 25th Mr. Richard Davy compressed the abdominal aorta by means of a metal lever introduced into the rectum, in a case of excision of cancer of the uterus, performed by Dr. Potter. The operation was almost entirely bloodless, and the pulsation in both femoral arteries was completely arrested. This procedure has not been followed by any untoward result.

ON Tuesday evening a Russian, who had been found lying insensible in Aldersgate-street, and had been placed in the infirmary attached to the City of London Union, at Mile-end, in a paroxysm of madness, attacked a man named Harris, and killed him by smashing his head with repeated blows with a chair. Was not this a case of delirium tremens ?

THE *Norwich Argus* has the following:—"Eliza Gedge, aged fourteen, was admitted an inmate of the Norfolk County Asylum at Thorpe in January, 1876, as an epileptic patient. She came from Burton Turf, in the Smallburgh Union, and was the daughter of one Martin Gedge, supposed to be a wherryman. On the early morning of the 2nd inst. she was put into a bath, prepared by the deputy head nurse, Clara Rump, by two attendants named Chilvers and Burdett. She was taken out again and conveyed to her ward, when it was found that she was severely scalded: she died from the effects on the evening of the 5th. On the 7th a post-mortem examination disclosed the fact that death was due to collapse of and shock to the system, caused by scalding. There was ulceration of the small intestine, one of the symptoms of burns or scalds, which alone would have caused death in a short time."

A SECOND death from hydrophobia occurred in Edinburgh last week. The patient, a young man from Loanhead, had been bitten in the hand two months ago, while assisting some others to kill a stray dog. Suspicious symptoms first developed themselves on Monday night (June 21st); he was admitted to the infirmary on Thursday, and died early on the following morning. No benefit was received from the administration of chloroform or chloral. Post-mortem examination was not allowed. A highly-coloured and sensational account of the case appeared in one of the local papers.

SEVERAL cases of fever, erroneously termed "famine fever," have recently occurred in the west of Ireland; but on an inquiry being instituted they have proved to be cases of typhus fever. Measures have been adopted for the relief of the sufferers, and every precaution will be taken to prevent the further spread of the disease.

MR. EDWARD HYACINTH O'LEARY, L.K.Q.C.P.I., of Birmingham, against whom a verdict of manslaughter was returned by a coroner's jury, at an inquest on the body of a parish patient, has been dismissed by the stipendiary magistrate, who remarked that he should not be justified in committing Mr. O'Leary for trial.

THE proposal to establish a University College in Liverpool appears to be receiving considerable favour. Already a sum of £60,000 has been collected in furtherance of the project, the amount required being £75,000, or an annual income of £3000.

THE new Bill to regulate the practice of medicine in the State of New York, which requires all physicians to present their diplomas and register before the 1st of October, 1880, has passed the Legislature and received the Governor's signature.

SEVEN acres of land in Park-lane, Croydon, have been purchased by the Local Board of Health for the purpose of being converted into an ornamental public park. The cost of the land, laying out, &c., is estimated at £14,000.

IN consequence of want of funds to meet the necessary expenditure, the Board of Meath Hospital, Dublin, have been compelled to close twenty-five beds, which will be reopened at the earliest opportunity.

DR. BATEMAN, of Norwich, has been elected a corresponding member of the Psychological Society of St. Petersburg.

THE Herts Convalescent Home is to be opened on the 21st of October by H.R.H. the Princess Christian.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool (estimated population 1880, 538,338).—Dr. Stopford Taylor's report for the year 1879 shows a birth-rate of 39.5 and a death-rate of 27.5. The low temperature of the winter months and generally of the year was followed by a great increase in the deaths from lung diseases; but the cold and stormy summer was accompanied by a lessened number of deaths from diarrhoea, these indeed being fewer than ever before recorded in the borough. "In a great community like ours," observes Dr. Taylor, "there will always be a large amount of animal and vegetable matter undergoing decomposition, and the atmosphere will contain various noxious effluvia; it will therefore be readily understood how the past summer was so healthy when we consider how putrefaction was retarded by the cold, the atmosphere washed of its impurities, the street-drains cleansed by the rain, and the perfusion of the courts and narrow streets promoted by the high winds." "Fever" ("typhus" of the Registrar-General's nomenclature) continues to decline in Liverpool, and Dr. Taylor confidently hopes that it will shortly become a disease of comparatively rare occurrence there. The deaths from fever were only 248 in 1879, as compared with an annual average of 493 for the preceding ten years. Scarlet fever and measles were the most prevalent of the infectious diseases occurring during the year. No less than 3857 cases of infectious diseases were reported to the health officer, and of these 710 were removed to hospital, 244 by the sanitary officers.

Under the Contagious Diseases (Animals) Act, 1878, 2099 cow-keepers and dairymen made application for registration, but of these only 1223 had their applications granted. Among the items of sanitary work done in 1879 we notice especially the conversion of 2115 privies into waterclosets, and the addition of 1018 pipe-ventilating shafts, fitted with Archimedian extractors to the sewers. We are glad to note this diminution in the number of the execrable privies which still discredit many parts of Liverpool, and the increased and increasing ventilation of the sewers.

Dr. Taylor has some interesting observations upon the returns of sickness required by the Local Government Board in relation to Liverpool. The difficulties of preparing the returns in that borough would appear to be insuperable. It would seem, for example, that in the parish of Liverpool alone, with a population of 205,338, between 20,000 and 30,000 sick persons pass yearly through the parish hospital on Brownlow-hill. There is also the Mill-road Hospital of the West Derby Union, which contains not only the sick paupers of Everton (population 128,477), Kirkdale (population 55,371), and West Derby wards (population 61,832), but those from Bootle, Walton, and West Derby &c., outside the borough. And there is the Toxteth Workhouse Hospital outside the borough, which accommodates the sick paupers from the Toxteth wards (population 87,320) within the borough. During the year 1878, 188,416 cases were treated gratuitously in the Medical Charitable Institutions of Liverpool, besides pauper cases—a number, Dr. Taylor remarks, "far beyond anything that could be expected in any English city or town, and can only be accounted for by many people attending first at one institution and then another, and thus being enumerated over and over again."

Reading, Urban (estimated population 40,000).—Dr. Shea reports for 1879 a death-rate of 19.2 per 1000 population (1878, 22.2), and a birth-rate of 36.7 per 1000. With the exception of measles, there was no particular prevalence of zymotic diseases, and "summer diarrhoea" was entirely absent. Reading would appear to be increasing rapidly, and it would seem doubtful from Dr. Shea's report whether the activity of the sanitary authority fully keeps pace with the augmenting sanitary needs of the place as to houses and population. It is true that Dr. Shea refers to the recent adoption by the sanitary authority of a series of bye-laws, but he observes that these bye-laws are not so stringent as the "model" bye-laws of the Local Government Board. The sanitary authority does not appear to have either

hospital accommodation or proper disinfecting apparatus, although both, it may be presumed, are necessary to effective sanitary work in an important town like Reading.

Taunton (Rural and Urban).—Dr. Henry J. Alford sends us his reports for the year 1879. The rural sanitary district of Taunton (population in 1871, 20,565) had a birth-rate of 25·8 per 1000 population, and a death-rate of 18·5. The mortality during the year was considerably above the average of the preceding six years, apparently owing to the severe weather which prevailed in the early months of the year, and which caused a high death-rate from respiratory disorders. But the cold summer which followed was not without its advantages, for there were no deaths from infantile diarrhoea. The urban sanitary district of Taunton (population in 1871, 15,446) had a birth-rate of 29·8 per 1000 population, and a death-rate of 23·9. Dr. Alford remarks, however, that the health of the town in 1879 was good, although the death-rate was high. The inclemency of the weather in the earlier part of the year cut off a great number of old people, but there was a steady diminution in the number of deaths from preventable diseases, "those diseases which in former years caused so heavy a mortality, and which are due so largely to a total disregard of the laws of health, both on the part of the authorities and the public at large." Dr. Alford relates a curious incident of an explosion from the accidental ignition of light carburetted hydrogen which had accumulated in the large vaulted receiving tank at their sewage works. Insufficient means for ventilation of the tank had been provided, and the gas had collected beneath the arched roof. The man in charge having opened the tank, and lowered into it an unprotected lamp, the gas ignited explosively, injuring the man and damaging the vaulted cover. In both reports Dr. Alford refers to the completion of the infectious-disease hospital erected by the two authorities, and of the advantages which have already been derived from its use.

Cambridge, Urban (estimated population 34,000).—Dr. Bushell Anningson reports a diminution of mortality in 1879 as compared with 1878, chiefly from the lesser number of deaths which occurred from zymotic diseases in the former years. The death-rate of 1879 was 18·0 per 1000 population, and the birth-rate 27·0 per 1000. There would appear to have been a decrease of mortality from pulmonary phthisis since the more complete drainage of the district. In some places the subsoil water, Dr. Anningson states, has been lowered 6 ft. The prevalence of zymotic diseases presented little for remark during the year, except in the case of diarrhoea. This malady was almost wholly absent (although very prevalent in 1878), and to this absence was chiefly due the diminished mortality. The results presented by the supervision of the town for sanitary purposes are not, Dr. Anningson observes, as satisfactory as could be wished, and he indicates certain insufficiencies in the Public Health Act, 1875, and the Artisans and Labourers' Dwellings Act, which interfere with the effectual action of a sanitary authority in certain matters.

THE MUNICIPALITY OF LONDON BILL.

Mr. Firth, Mr. Thorold Rogers, and others have prepared and brought into the House of Commons a Bill for creating a Municipality and County of London. In the preamble the Bill sets forth that it is expedient there should be instituted for London one central representative municipal authority. It proposes to term this authority the "Municipality of London," and to give it all the powers and authorities now vested in and exercised by the Lord Mayor, aldermen, and commonalty of the City of London, the Metropolitan Board of Works, the metropolitan vestries and district boards, and all other bodies, boards, officers, commissioners, or other person or persons exercising municipal functions under any statute, local or otherwise, within the metropolis. The Bill further proposes to constitute the metropolis a county of itself, by the name of the County of London, and to make provision respecting justices of the peace and county officers and others in and connected with the County of London. In place of the present districts into which London is now divided, the Bill would substitute forty municipal districts. Plans attached to the Bill show the existing districts and the districts contemplated in the proposed measure.

MUNICIPAL MORALITY.

A deputation of the Rotherham Town Council had an interview with the President of the Local Government

Board for the purpose of inducing him to assent to a loan of £6000 from the Public Loan Commissioners for provisional sewerage works. The Town Council were called upon to divert the sewage of the borough from the river Don, and, in support of their application, they stated that the insanitary state of particular districts of the borough "exceeded description." They wanted the loan to do certain provisional works, while they could mature a more comprehensive scheme, and added, if the loan were refused and an epidemic were to break out, they should hold the Local Government Board responsible! Mr. Dodson very properly refused to grant the loan. The scandalous condition of parts of the borough and of its sewerage described by the deputation was, in fact, the result of the deliberate neglect for years by the local authority of their sanitary duties; and the application for a loan for provisional works was simply an application for costly delay at the expense of the ratepayers. Mr. Dodson would be prepared to consider the question of a loan when a properly-matured plan was submitted to him.

REPORTS OF THE MEDICAL SUPERINTENDENTS OF THE STOCKWELL FEVER AND SMALL-POX HOSPITALS.

The reports of the medical superintendents of the Stockwell Fever and Small-pox Hospitals (Dr. P. H. McKellar and Dr. Francis R. Bernard), for the year 1879, contain little but the movement of patients during a comparatively uneventful year so far as these hospitals are concerned. The patients admitted into the fever hospital under Dr. McKellar numbered 1001, of whom 813 suffered from scarlet fever, 106 from enteric fever, 39 from typhus, and 43 from other diseases. No instance occurred of any of the patients contracting illness in the wards other than that he or she was affected with at the time of admission; and no instance came to Dr. McKellar's knowledge of persons who had visited the wards for the purpose of seeing friends dangerously ill having become infected themselves or conveying infection to others. The patients admitted into the Small-pox Hospital under Dr. Bernard's care numbered 146. The available figures as to the mortality from the disease in this hospital, in relation to admissions since its opening in 1871, seem to show a marked declension; and Dr. Bernard expresses the opinion that this may be due to recent improvements in the sanitary condition of the hospital and to systematic measures of thorough cleansing. Dr. Bernard, indeed, attaches a degree of importance to general insanitary conditions in the development of small-pox not usually held with reference to that disease.

THE REGISTRATION OF INFECTIOUS DISEASES IN BLACKBURN.

We learn from a correspondent in Blackburn that the Town Clerk of that municipality has given it as his opinion that it is a duty of the Medical Officer of Health "to visit and inspect all cases of infectious disease as defined by the Act." We fail to find a definition of infectious disease in the Blackburn Improvement Act of 1879, or any description of the duties of a Medical Officer of Health; and if the Medical Officer of Health is performing his duties according to the Regulations of the Local Government Board, we shall be surprised to find that Board interpreting them, so far as they relate to infectious disease, in the same sense as the Town Clerk of Blackburn.

SMALL-POX IN BATH.

At a meeting of the Bath Board of Guardians, on the 16th ult., a report was read from the Finance Committee setting forth that 178 cases of small-pox had been received into the workhouse during the epidemic of small-pox just ended, and recommending gratuities to the various officials, of the Guardians, medical and others, upon whom had been thrown extra work, and who had been exposed to special risk by the outbreak. The report was agreed to.

At a meeting of the Bristol Sanitary Authority on the 17th ult., Mr. Davies referred to the Vaccination Amendment Bill now before Parliament, and expressed his apprehension that the contemplated relaxation of the penal provisions of the Vaccination Act would have a most injurious influence upon the maintenance of efficient vaccination in Bristol. A conversation took place upon the subject, and the clerk to the Authority and Mr. Davies were instructed to prepare a memorial, setting forth how the Vaccination Act had worked

in Bristol, and the good effects it had had, and expressing the fear of the Authority that the result of the Bill, if it became law, would be to lessen the amount of vaccination, and thus promote the increase of small-pox.

On the 14th ult. a sewage-farm of fifteen acres, which has been prepared for the Sanitary Authority of Halsted, in Essex, by Messrs. Bailey Denton, Son, and North was first brought into operation. The sewage has to be lifted on to the land, and this is effected by a windmill having a self-acting sail thirty feet in diameter, and driving a Noria chain-pump, to which are attached forty-six buckets, each carrying a gallon.

The Corporation of Liverpool have come to an arrangement with the Conservators of the Severn Fishery District, and the latter have withdrawn their opposition to the scheme of the Corporation for taking water from the upper affluents of the river.

VITAL STATISTICS.

HEALTH OF LARGE ENGLISH TOWNS.

The unusually low rate of mortality that has recently prevailed in our large English towns still continues. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5204 births and 2716 deaths were registered last week. The births were 19 above, whereas the deaths were no less than 559 below, the average weekly numbers during 1879. The deaths were within one of those returned in the preceding week, and were equal to an annual rate of 18.9 per 1000, against rates declining steadily from 22.7 to 18.9 in the ten preceding weeks. During the past twelve weeks of the current quarter the death-rate in these towns has averaged only 20.6 per 1000, against 23.7, 22.6, and 22.6 in the corresponding periods of the three years 1877-78-79. The lowest death-rates in the twenty towns last week were 12.6 in Brighton, 14.4 in Bristol, 15.2 in Norwich, 15.3 in Plymouth, and 15.7 in Salford. The rates in the other towns ranged upwards to 21.5 in Sunderland, 23.1 in Nottingham, 23.6 in Liverpool, 24.0 in Manchester, and 27.1 in Oldham. The comparatively high death-rates in these last-mentioned towns were, with the exception of Nottingham, due to excessive zymotic fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 406 and 419 in the two preceding weeks, further rose last week to 432; these included 123 from scarlet fever, 103 from whooping-cough, 76 from diarrhoea, and 63 from measles. The annual death-rate from these seven diseases averaged 3.0 per 1000 in the twenty towns; it was but 0.7 and 0.8 in Wolverhampton and Leicester, whereas it ranged upwards to 5.6 and 7.6 in Salford and Sunderland. Scarlet fever showed the largest proportional fatality in Salford, Sunderland, Bradford, and Newcastle-upon-Tyne; measles in Oldham and Sunderland; and whooping-cough in Liverpool, Manchester, and Birmingham. Two deaths were referred to diphtheria in Salford. Small-pox caused 14 more deaths in London and one in Manchester, but not one in any of the eighteen other large towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the two preceding weeks had been 221 and 229, further rose to 237 on Saturday last, a higher number than in any week since the beginning of April, 1879; 47 new cases of small-pox were admitted to these hospitals during last week, against 31 and 50 in the two previous weeks. The number of patients in the Highgate Small-pox Hospital was 11, against 13 and 9 in the two preceding weeks.

The fatality of lung diseases showed a further decline last week. The deaths referred to diseases of the respiratory organs in London, which had been 230 and 198 in the two preceding weeks, further fell last week to 176, and were 19 below the corrected weekly average; 94 deaths were referred to bronchitis, and 52 to pneumonia. The annual death-rate from diseases of this class did not exceed 2.5 in London, whereas the rate from the same diseases was equal to 4.1 in Liverpool, and 3.1 in Salford.

HEALTH OF LARGE SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20.5 per 1000, against 24.8 and 20.6 in the two preceding weeks;

this rate exceeded by 1.6, or 8 per cent., the average rate in the twenty large English towns. The rates last week in the eight Scotch towns ranged from 13.1 and 19.1 in Greenock and Aberdeen to 27.3 in Perth, and 27.6 in Paisley. The 95 deaths referred to the seven principal zymotic diseases in the eight towns showed a decline of 3 from those returned in the previous week, and included 22 from diarrhoea, 21 from whooping-cough, 18 from measles, and 12 from scarlet fever. The annual death-rate from these seven diseases averaged 3.8 per 1000 in the eight towns, against 3.0 in the twenty English towns; this zymotic rate, which was but 1.3 and 3.0 in Greenock and Aberdeen, ranged upwards to 6.4 and 7.8 in Paisley and Perth. The 21 deaths from whooping-cough showed a considerable decline from recent weekly numbers; of these, 8 occurred in Glasgow and 4 in Edinburgh. The 13 fatal cases of fever showed a slight further increase upon those returned in the two preceding weeks; 9 occurred in Glasgow, 2 in Dundee, and 2 in Perth. The fatality of fever again showed a marked excess upon the fever fatality in the twenty large English towns, and was proportionately greatest in Perth. The deaths from measles, which had been 28 and 24 in the two previous weeks, further declined to 18, of which 10 occurred in Glasgow, and 4 in Edinburgh. The 12 fatal cases of scarlet fever included 6 in Glasgow, 3 in Edinburgh, and 3 in Leith. The deaths in these eight towns from acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy), which had been 116 and 88 in the two preceding weeks, further declined last week to 79, and were equal to an annual rate of 3.2 per 1000. The rate from the same diseases in London last week did not exceed 2.1 per 1000. The recent excess of mortality in the Scotch towns has been due to the high death-rate from lung diseases, and from zymotic diseases.

THE HEALTH OF DUBLIN.

The last return shows a further improvement in the health of Dublin. The annual rate of mortality within the city, which had been equal to 42.5 and 39.3 in the two preceding weeks, further fell last week to 32.7 per 1000, a lower rate than has prevailed in any week since the beginning of April. The annual rate of mortality in Dublin during the past twelve weeks of the current quarter, without any correction for defective registration, has averaged no less than 36.8. In London, during the same period, the death-rate has not averaged more than 19.5 per 1000. The 197 deaths in Dublin last week included 48, or 24 per cent., which were referred to the seven principal zymotic diseases, against 65 and 53 in the two preceding weeks; 19 resulted from small-pox, 9 from measles, 8 from fever, and 5 from scarlet fever. The annual death-rate from these seven diseases was equal to 8.0 per 1000 in Dublin, against 2.7 both in London and in Edinburgh. The fatal cases of small-pox, which had been 13 and 14 in the two preceding weeks, further rose last week to 19, and exceeded the number returned in any week since the end of February, 1879.

THE MORTALITY OF ST. PETERSBURG.

The mortality of St. Petersburg for the week ending the 15th May numbered 759 (507 males and 252 females). The deaths from "typhus" were 155, the largest number from any one cause; and next in order came pulmonary phthisis, 119. Thirty-six deaths were assigned to "blood-infection." In the following week, ending the 22nd May, the total mortality fell to 689 (480 males and 259 females). Again the deaths from "typhus" (127) were most numerous; 44, moreover, were attributed to maculated typhus (*typhus pourpre*); 10 to diphtheria; and 123 to pulmonary phthisis.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

LORD BEACONSFIELD ON CEMETERIES.

The sanitary spasm which seized Lord Beaconsfield when he addressed the House of Lords on the third reading of the Burials Bill forms a curious episode in the political history of that remarkable man in recent years. The cynical indifference which he manifested towards public-health matters when lately in office was not less incongruous with his apophthegmatical utterance immediately previous to entering upon office,—to wit, *sanitas sanitatum omnia sanitas*,—than his fulmination against burial-grounds, on health considera-

tions, in the discussion on the Burials Bill. There was a painful want of reality in the expression of opinion that the time was at hand when we should become convinced that the institution of churchyards is one which is highly prejudicial to the public health, and that it would be a much wiser step if we were to say that the time has arrived, seeing the vast increase of population in this country and the increase we may contemplate, when we should close all these churchyards, and take steps for furnishing every community with a capacious and ample cemetery. The confusion here between the burial requirements of communities in towns and communities in villages and hamlets, and the relations of the increase of population to these several communities as regards questions of health and of fact, is, it seems to us, hopeless.

MEDICO-SANITARY NEWS FROM RUSSIA.

It is reported that the measures for the sewerage of Warsaw advance only very slowly. Two years must elapse, it is said, before even the preparatory works will be completed. — The project of certain zemstvos to establish dispensaries for the poorer classes of their population is prevented from being fully carried out by certain privileges which, according to existing law, are attached to free dispensaries belonging to private individuals. — The *Voice* remarks that "one of the most deplorable aspects" of the present imperfect sanitary organisation which exists in Russia is the want of proper means for transporting the sick of all kinds to hospital. — The *Odessa Messenger* "deplores" the failure of municipal administration in that city, observing that, with a population of 200,000, there are neither hospitals nor asylums of sufficient capacity to meet the wants of the community. It refers also to the want of markets, and particularly of a cattle market, for the reception of cattle brought into the city—a deficiency peculiarly felt in view of dealing with contagious epizootic diseases. These important needs are sacrificed to the building of a grandiose theatre—two already existing in the city, and one of these of very great dimensions. — The Central Committee for the Protection and Aid of Wounded Soldiers have latterly been giving particular attention to those who have suffered from wounds and injuries to the eyes. MM. Strebnitsky and Talke, "oculists," have been visiting the soldiers thus injured in various parts of the empire, with a view to their assistance pecuniarily and otherwise. — Diphtheria is reported to be declining in Podolia. This result is attributed to the energetic measures which have been adopted for limiting the disease by the local Red-Cross Society. The Society has given 48,000 roubles towards the fund for dealing with the malady.

THE NEW YORK STATE BOARD OF HEALTH.

An Act has passed the Senate and Assembly of the State of New York establishing a State Board of Health. The Act provides for six Commissioners (two to be medical, who may be graduates of good standing from any State) holding office for three years. Three of these Commissioners are nominated by the Governor and confirmed by the Senate; the other three are selected and appointed by the Governor from the health commissioners of the municipal boards. The health officer of the port of New York, the attorney-general, and the director of the State Survey are appointed *ex officio* members. The Commissioners appointed are as follows:—Hon. Erastus Brooks, John S. Delavan, M.D., and Elisha Harris, M.D. (nominated by the Governor and confirmed by the Senate), Professor C. F. Chandler, E. M. Morse, M.D., and J. G. Hunt, M.D. (appointed by the Governor), W. M. Smith, M.D. (health officer of the port of New York), the Hon. Hamilton Ward (Attorney-General of the State), and James T. Gardner, C.E., director of the State Survey (*ex officio*).

MEDICAL AID IN RUSSIA.

The Russian journal the *Voice* takes a gloomy view of the position of the poorer classes of the empire with reference to medical assistance. It derives its data from the report of the Medical Department of the Imperial Government for the year 1878. There was a greater pressure upon the public means for medical assistance in that year than in 1877, and the insufficiency of the resources to meet the demands made upon them was in consequence most conspicuously shown. The applications for aid far exceeded the number of beds available for the sick, and very many, therefore, could not

have such care as they needed for the proper treatment of their ailments. No less than 7000 patients were refused admission into the hospitals of St. Petersburg, in 1878, for lack of room. The proportion of hospital beds to the population of the empire is given as 1 in 1540. Over a million cases of sickness were prescribed for by the medical staffs as out-patients, but doubts are expressed as to the value of treatment in this fashion under the circumstances in which the poorer Russian classes live. The hospitals in the rural districts rendered great services, not less than 657,126 patients having been treated in them during the year. The average mortality in the Russian hospitals in 1878 was 8.6 per cent. of the admissions, and it ranged from 2.4 per cent. in the hospitals of the territory of Semipalatinsk to 12.7 per cent. in the hospitals of the government of Oufa. The mortality in the hospitals of St. Petersburg was 11.3 per cent.

DUBLIN SEWERAGE.

An extensive series of sewerage works are at present being constructed by the Corporation of Dublin at the north side of the city, and will be completed in about eight or nine months. The districts at present completed or in course of construction comprise various portions of the city, which heretofore were in a most insanitary condition. When the main drainage scheme is completed these sewers will be connected with it; but until that time arrives the greater portion will discharge their contents into the different main sewers, having outlets to the river. There is no doubt that when the north and south contracts are finished that they will have an appreciable effect on the health of those residing in those particular districts.

OPHTHALMOLOGICAL SOCIETY FOR GREAT BRITAIN AND IRELAND.

A MOVEMENT was set on foot several months ago by some gentlemen in London interested in the progress of ophthalmic medicine and surgery for the establishment of an Ophthalmological Society for the United Kingdom. The efforts of its promoters have been so far successful that a large number of the leading ophthalmic surgeons in the three kingdoms, and several physicians who take a special interest in diseases of the eye in their medical aspects, have consented to form the nucleus of the Society. The first meeting of those who had been invited to take a share in its inauguration was held on the evening of the 23rd ult., at the rooms of the Medical Society of London. About thirty of the sixty gentlemen who have already joined were present, including most of the leading London ophthalmic surgeons and several from the provinces, and resolutions were passed constituting the Society and appointing officers. The chair was occupied by Mr. Bowman, who opened the proceedings with an able address. Mr. Bowman began by alluding to the much more important rank assigned to ophthalmology in the present day by our medical corporations, schools of medicine, and general hospitals than formerly, and paid a tribute to the long array of great English surgeons and oculists of the first half of the century who contributed so largely to place the theory and practice of the ophthalmic branch of surgery on a rational and scientific basis. The great advance in our knowledge of the nature and rational treatment of disease which was the immediate result of the improved methods rendered possible by the discovery of the ophthalmoscope and other instruments of exact research was dwelt upon, especially in relation to ophthalmic medicine and surgery. In alluding to the immense modern growth of ophthalmology and the natural tendency in a department so extensive, and in some directions complicated, to fall into still further subdivisions, the origin of the present movement was briefly alluded to as the outcome of a want which had been long felt and which there had been more than one attempt to supply. A very general need was felt of greater facilities for encouraging work, discussion, and publication in ophthalmology. The only difficulty had been in deciding on the means most likely to be successful; whether a special Ophthalmological Society would be likely to prove more useful and meet with more support than the alternative plan of a special section at some one of the older

Societies. It was thought that the latter plan would have the fewer advantages, especially since some steps in that direction had, it was understood, been taken several years ago without any result. It was held that the sole objection to a separate special Society was that it might tend to encourage narrowness of view and work; but that this objection might fairly give way before the greater facilities for work which it would afford, more particularly as the Society already contained amongst its members a number of physicians and surgeons who were not specialists. An earnest hope was expressed that in the active co-operation of such colleagues the Ophthalmological Society would find much of its strength. In conclusion, it was not to be forgotten—it was indeed to be insisted upon—that of all the subdivisions of medicine, ophthalmology more than any other exemplified the means and methods which all should strive to master and employ who aimed at becoming worthy practitioners of the healing art.

The Chairman then proposed to the meeting, as the basis on which the Society should be formed, the following resolutions:—That the Society publish Transactions, and meet about five times a year, ordinarily in London; that the subscription be one guinea a year; that members should in future be elected by ballot; that the management be in the hands of a committee consisting of the President, Vice-Presidents, Treasurer, Secretaries, and nine other members.

It was proposed by Mr. Critchett and seconded by Dr. Hughlings Jackson, and carried unanimously: "That an Ophthalmological Society of the United Kingdom be formed," a hope being entertained that it would also embrace among its members those practising in India and the Colonies.

It was next proposed by Mr. Brudenell Carter, seconded by Mr. Henry Power, and carried *nem. con.*: "That honorary members, whose number shall not exceed four, be elected from gentlemen pre-eminently distinguished in ophthalmology or in the sciences bearing upon it."

It was proposed by Mr. John Couper, seconded by Dr. Allen Sturge, and carried *nem. con.*, that the following gentlemen form the Committee of the Society for the first year:—President: Mr. Bowman, F.R.S. Vice-Presidents: Mr. Critchett, Mr. Hutchinson, Dr. Hughlings Jackson, F.R.S., Mr. Teale (Leeds), Mr. Walker (Edinburgh), Mr. Swanzy (Dublin). Treasurer: Mr. Streetfield. Secretaries: Dr. Stephen Mackenzie, 26, Finsbury-square, E.C.; and Mr. E. Nettleship, 4, Wimpole-street, W. Other Members of Committee: Mr. J. E. Adams, Dr. Barlow, Dr. Brailey, Mr. Brudenell Carter, Dr. Gowers, Mr. Higgins, Mr. Hulke, F.R.S., Mr. Henry Power, and Mr. Waren Tay. As an amendment, Mr. Vose Solomon, whilst entirely approving the selection of names as regards London, moved, and Mr. Lloyd Owen seconded: "That, in order to make the committee as representative as possible, the number be increased by the addition of nine extra-metropolitan members." Messrs. Couper, Brudenell Carter, and Adams were opposed to the enlargement. Mr. Henry Power, agreeing in the main as to the disadvantages of large committees, suggested that three members might be added to the committee representing ophthalmic centres out of London. This suggestion was accepted by Mr. Solomon, and put from the chair, but lost.

It was proposed by Mr. Frederick Mason, and seconded by Mr. Spencer Watson, and carried *nem. con.*: "That the committee be empowered to draw up rules, to be submitted to the Society at its second meeting in the autumn of the present year."

A vote of thanks to the Council of the Medical Society of London, for the use of their rooms, was moved by Mr. Streetfield, and seconded by Mr. Higgins. The proceedings terminated with a cordial vote of thanks to the chairman, proposed by Dr. Gowers and seconded by Mr. Waren Tay.

Applications for membership, and intimations of intended communications, should be sent to the secretaries.

THE SERVICES.

THE AFGHAN WAR—CABUL FORCE.

OUR correspondent at Sherpur, writing last mail, reports the general health of the troops in Sir Donald Stewart's Division as very good. The force in the Logar valley under Sir Frederick Roberts, V.C., were in excellent condition and spirits, and although they had so far not exchanged a

shot with the enemy the "outing" had done them good. The days, although somewhat hot, 84° being registered in a tent at noon, were followed by cold nights, when a blanket was still a necessity.

A large number of Cabulees and Ghilzais wounded at the late action of Charasiab have been despatched to Cabul, and are treated by the medical officers in the dispensary, which is in the full swing of useful and humane work in the city.

Deputy Surgeon-General A. Smith, C.B., who arrived with Sir Donald Stewart, has, by virtue of seniority, become Principal Medical Officer of the army in Afghanistan, Deputy Surgeon-General H. Hassard assuming medical charge of General Roberts' Division. Men and officers are alike eager for a return to India as soon as the weather is sufficiently cool to allow of a return march through the Khyber; one and all are heartily sick of Cabul and the war generally.

By the retirement of Surgeon-Generals C. A. Gordon, C.B., and E. Gilborne, two more Deputy Surgeon-Generals will obtain promotion to the higher grade, Deputy Surgeon-Generals Sir A. D. Home, V.C., K.C.B., and W. A. Mackinnon succeeding to the vacancies. Sir Anthony Home remains at Madras, as Principal Medical Officer, and Dr. Mackinnon, who is at present in Hong Kong, will proceed to Malta, to assume the medical administration of that important station.

Surgeon-Major John Warren has been appointed to the medical charge of the Battery of Royal Horse Artillery stationed in St. John's Wood Barracks.

ADMIRALTY.—Staff Surgeon Alexander Turnbull, M.D., has been promoted to the rank of Fleet-Surgeon, with seniority of 2nd June. Fleet-Surgeon Thos. Browne, to Yarmouth Hospital, to date from the 1st July; Fleet-Surgeon Dr. Duncan Hilston, to Yarmouth Hospital, in charge, to date from the 1st July; Surgeons Henry T. Cox, to Bermuda Hospital; Robert F. Yeo, to Haslar Hospital; and Thos. M. Sibbald, to the Northampton.

Correspondence.

"Audi alteram partem."

A UNIFORM SYSTEM OF REGISTRATION OF DISEASE IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—The importance of the subject of registration of diseases in hospitals has not received the attention it merits from the governing bodies of these institutions. A considerable amount of very valuable information might be gathered from the large number of cases which must of necessity pass through the hospitals in the course of a year; and, from experience, I can state positively that a very considerable portion of this information is wasted, owing to the variety of the systems of registration at present in vogue. It is true that the subject is not entirely neglected, but only those who are brought into immediate contact with the cases are able to derive any benefit from them. The work of registration should be conducted in such a manner that the profession at large might be able to obtain satisfactory statistical and general information on any class of cases. Every hospital has at present an independent method more or less theoretically perfect, but in few cases capable of being carried out in detail. By a little pressure they can be reduced under one of two heads—the first, in which the registrars themselves record the cases; the second, in which the students perform the same duties subject to the supervision of the registrars—a work in many cases of superhuman labour. It is impossible at the present time to obtain satisfactory data from more than one or two hospitals, owing largely to this want of uniformity in method, a want which has already made itself felt, as the following quotation from the report of the special committee appointed to inquire into the subject of pyæmia, septicæmia, and purulent infection, will show:—

"Before passing from this part of the subject we would observe that, considerable as the number of cases collected in these statistics may be, still, spread as they are over a

number of years, they are insufficient to found definite conclusions upon, but may prove useful as suggesting points for future inquiry. They would have been, however, more conclusive than they are had the whole material of the London hospitals been available; but, unfortunately, owing to the absence of any uniform system of keeping the registers throughout the metropolitan hospitals, information given in some reports is not mentioned in others. It would be of immense value, especially in determining the etiology of disease, in points relating to their predisposing causes, if a uniform system of registration were adopted for all the metropolitan hospitals." (Trans. of Pathological Society, vol. xxx., p. 8.)

It is to this great want of *uniformity* that I desire especially to call attention. If such an influential body of men as the medical and surgical registrars of the London hospitals were to meet together and consider the subject, it would be possible for them to draw up such a system of registration as would include all the good points of the varied systems now in vogue, and one capable of universal adoption. It would be impossible, then, for any special committee to make such a statement as that to which allusion has been made, and which will remain for ever as a blot on the well-intended but ill-directed labours of the present system of registration.

I am, Sir, yours, &c.,

E. H. HOWLETT, F.R.C.S.,

Late Surgical Registrar to King's College Hospital.

June 28th, 1880.

"SLEEPING GIRLS."

To the Editor of THE LANCET.

SIR,—Will you allow me space in which to refer to a case—"The Sleeping Girl of Turville"—about whom a communication from Mr. Hayman, of Stokenchurch, appeared in the pages of your journal of the 12th ult.

This girl, now twenty-one years of age, has, it appears, been lying on her side with her hand under her face, and without apparent adequate means of sustenance, since March, 1871. She was alive on the 15th of May last. She has been "visited by numerous medical men from all parts, and, I believe," says Mr. Hayman, "without any exception, with more or less scepticism,"—i.e., I apprehend, as to the one position having been maintained for so long a period, and her alleged "fasting"—not perhaps to be accepted in its *severest* sense.

Such cases have not been uncommon. I remember to have had one in every respect similar whilst at the Royal Free Hospital. The facts in relation to which might be of use if turned to account in the treatment of another such case.

The patient, a girl of about the same age as Mr. Hayman's patient, was from a village in Essex, where she had long been popularly known as the "sleeping beauty," and largely visited by persons from far and near, mostly moved by such various phases of emotion as the sense of the supernatural would awaken. There was no deception, actual or intended. The doctors, the clergy, even the village conjuror, had been tried, but without benefit; at last she was sent to one of the large London hospitals, but still in vain.

When she came to the hospital under my care she took the position in bed assumed by Mr. Hayman's patient—apparently asleep, with a subdued sigh and a gentle movement of the body on each inspiration, but still alive to a cup or spoon containing liquid food when applied to her lips. Of this she took but little, and of solid food, as far as I knew, none—showing on how small a quantity of sustenance the body can be kept alive. I do not remember whether the stomach-pump was used, but I think not; for a remedy soon occurred to my mind, and with the consent of the friends I lost no time in making trial of it.

I had a grain of tartar emetic placed on the back of the tongue. The girl began to show signs of awaking to the dismal consequences of the salt's activity. She soon sat up, and was persuaded to assuage her trouble by draughts of lukewarm water, and later to solace them by a little brandy as well. When these effects had subsided, she relapsed into her former condition, when, after an interval of twenty-four hours, another dose was administered, and was followed by like effects. She was much disgusted with the process, but after another period of

wakefulness she once more relapsed. A third dose was ordered, *in her hearing*, when she roused herself, and once and for all refused to submit. The remedy had done its work; the patient took food, got out of bed, began to move about the ward, and, with the terrors of the "third dose" before her mind, made such recovery that in the course of a very few days she packed up her boxes and started home.

The "sleeping beauty" was thus transformed into a useful handmaiden in her mother's cottage; and a few years ago, happening to be in the neighbourhood, and being reminded of the incident, I called, and found her a robust, active and intelligent young woman, still with a keen recollection of the occurrence I have related, not unmixed with gratitude.

I am, Sir, your obedient servant,

June 16th, 1880.

JOHN GAY.

HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—On the 25th of May a dog, supposed to be rabid, was seen in the neighbourhood. This animal bit the following persons to my own knowledge:—W. M., on the calf of the leg; Mary R., on the right ear and right thumb; D., on the left cheek; H., G., and F., on the forearm; E., on the hand; and, besides, five dogs and two oxen. The brute was followed up, shot, and subsequently buried. On the 27th the carcass was exhumed, and a post-mortem examination was made by a local veterinary surgeon, whose verdict was that the dog was not afflicted with rabies, and who asserted that his mysterious conduct was caused by some wool found in the stomach, which produced intense uneasiness.

All the wounds of the fore-mentioned were immediately washed out and cauterised with strong nitric acid, and poultices were applied, and one was also excised. With the following exception none of these cases have hitherto evinced hydrophobic symptoms.

On the 15th of this month I was asked to visit Mary R.—I found her very restless and feverish. She had previously complained of giddiness and of a varying temperature, being at one time very hot and at another extremely chilly. I next saw her on the morning of the 16th, and immediately made my diagnosis as hydrophobia. The following symptoms characteristic of this disease tended towards confirming the above—viz.: (1) Frequent convulsive seizures caused by the least excitement; (2) acute sensibility of the general surface; (3) spasms of the respiratory muscles and of the muscles of deglutition.

I immediately placed the case under the care of a trained nurse, ordered the room to be darkened, and the bed to be surrounded with thick gauze curtains, so as to prevent any currents of air passing over the patient, and to exclude all rays of light, since both the above excited the convulsions. I also prescribed bromide of potassium and aromatic spirits of ammonia, with a view to lessening the acuteness of the paroxysms. She had an intense horror of fluids, and the simple act of pouring out a liquid for her in her hearing, or even mentioning the name of water, was sufficient to bring back the most violent convulsions.

About the thirty-sixth hour after the first appearance of the disease the symptoms gradually subsided, the acute sensibility disappearing entirely. She remained in this state till her death, which took place from exhaustion at 4 o'clock on the afternoon of the same day. What makes this case all the more curious is that, although she had previously entertained the most inveterate horror of all liquids, she asked for water about half an hour before she died.

Of the dogs, two were immediately shot, and the remaining three evinced very peculiar symptoms—one of them died after a day's indisposition, and the owners were prompted to destroy the other two.

Lastly, one of the oxen became mad, and was shot on the 22nd, and the conduct of the surviving one is so much out of the common that the owner is treating it with popular remedies for this disease.

In conclusion, I would ask, if the dog was not rabid, how can these symptoms be accounted for?

I remain, Sir, yours very faithfully,

J. HOPKIN DAVIES,

Surgeon to the Margam Copper Works.

Tir Caradoc, Taibach, June 26th, 1880.

THE ARREST OF HÆMORRHAGE DURING AMPUTATION AT THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—The question of the best method of arresting hæmorrhage during amputation at the hip-joint has been recently discussed at the Clinical Society and in your columns. I should like to be allowed to draw attention to an application of Esmarch's elastic tourniquet—not, as far as I can discover, mentioned in his "Surgeon's Handbook," though it has probably been often employed before—which I found, in amputating at the hip in a boy fourteen years of age, answer its purpose perfectly, without causing the slightest inconvenience to the operator.

The limb was first elevated in order to render it bloodless, and when this result had been obtained the pelvis was raised from the table, and the india-rubber band was placed loosely in the perineum, after slipping it through two loops of bandage, one in front and one behind, which were drawn across to the opposite side of the body and held firmly above the iliac crest by an assistant. The two ends of the india-rubber band were then drawn rapidly and tightly outwards, were crossed below the iliac crest of the side on which the amputation was to be performed, and were then made to encircle the pelvis once, passing on the opposite side between the iliac crest and the great trochanter. The arrangement of the loops of bandage and of the india-rubber band will be gathered from the accompanying sketch.

* Great trochanter.

This method has the advantage of compressing the vessels in the posterior flap as well as the commencement of the common femoral, and it enabled me to perform the oval amputation quite bloodlessly, and as slowly as was desired. As the band does not pass round the waist, no fear need be entertained of its interfering with respiration. It remains to be seen whether it is equally applicable to the large thigh of a muscular adult as to the small one of a boy of fourteen.

I am, Sir, yours truly,

RICKMAN J. GODLEE.

Henrietta-street, Cavendish-square, June, 1880.

"THE LANCET" COMMISSION ON WORKHOUSE INFIRMARIES.

To the Editor of THE LANCET.

SIR,—In reference to your introductory remarks in your issue of the 22nd ult., in favour of an entire separation of the sick poor from the pauper class, I beg to offer the following remarks in support of your proposition, based on an experience of over twenty years as one of the guardians of the Cork workhouse, which contains at present a population of 2683 persons.

The great object that we all ought to have in view is the prompt and efficient relief of the destitute and the sick poor at the lowest possible cost consistent with the efficient treatment of them.

The massing-up of human beings composed of all the varied classes in workhouses, such as the convicted and unconvicted criminal, the drunkard and vicious of both

sexes, together with the well-conducted destitute poor persons, is a sad mistake; the system tends to perpetuate crime and all its sad accompaniments, while an increasing poor-rate declares in unmistakable language the evil results of our poor-law system.

Separation of those classes appears to me to be the only remedy. Why should the honest, well-conducted poor man or woman, who seeks hospital relief, be placed in a ward with the rogue and vagabond? Why should the former, when recovering, be compelled to sleep in a bed with the latter? Why should the innocent child over three years of age, when sent in for hospital treatment to a workhouse, be placed in the adult wards of the hospital? Is it not proved by experience that evil associations are the ruin of our people. Yet in all the Irish workhouses will be found no separate wards for the well-conducted and the badly-conducted classes, notwithstanding that the workhouse regulations appear to provide for the separation of the children from the adults; and although they have separate wards to live in when they are in health, strange to say, when they become sick they are placed in the hospitals with the adults. Imagine for a moment a young lad associating in a sick-room with a pickpocket or a thief. Here lies the root of one of our sources of criminals, and it is no wonder that our workhouses under these circumstances should supply the ranks of the criminal classes.

Let a beginning be made, such as you suggest, in the way of separate hospitals, removed altogether from workhouses, where the working man or his wife or children can receive medical treatment without the danger of the evil associations of a workhouse; and when they are recovered and fit to leave the hospital, let them not be permitted to remain, as they are in workhouses. "Once in a workhouse always in a workhouse" is becoming a proverb, and although the annual mortality in the Cork workhouse is upwards of 600, the numbers in the house are steadily increasing, and they will continue to do so until a separate hospital is provided, or the healthy persons kept in some other institution.

I am, Sir, yours &c.,

Cork, June 6th, 1880.

WM. D'ESTERRE PARKER.

ON THE EXCISION OF OBSTRUCTION AT THE NECK OF THE BLADDER.

To the Editor of THE LANCET.

SIR,—Mr. Teevan's reply furnishes a complete warrant for my calling in question his statement, that there are "hundreds of men now alive to whom Mercier has restored the faculty of free and natural micturition." He quotes Mercier's own statement as follows:—"Car mes opérations s'élèvent au moins au nombre de trois cents;" but it will scarcely perhaps be believed that this is only half the sentence; the other half, omitted by Mr. Teevan, being: "certains de mes malades ayant été opérés plusieurs fois," proving that Mercier himself is desirous to explain the large and incredible number of his cases by saying that on several he has operated many times. The other writers named by Mr. Teevan speak not on their own authority, but only on that of Mercier, like Mr. Teevan, not having done the operation themselves. Mr. Gouley, whom he cites in his favour, particularly speaking of the operation with disapproval.¹

What now becomes of the number of patients? And, still more important, what becomes of the value of the operation itself, which must be so often repeated? As to these cases of Mercier's, all performed more than thirty years ago, it would be curious to speculate on the ages of the old gentlemen supposed still to be perambulating Paris. The fact is, as I originally stated, a few cases were done by Mercier only or chiefly many years ago; the proceeding has long since fallen through as useless and dangerous, and no surgeon of eminence in Paris ever does it.

I must omit, as irrelevant to the present subject, the consideration of the side-issue started by Mr. Teevan, of the removal of prostatic tumours, whether accidentally or purposely, in the operation of lithotomy or by the special device of cystotomy. What I undertook to impugn was Mr. Teevan's advocacy of Mercier's operation of incising and excising prostatic obstructions by means of instruments passed down the urethra.—I am, Sir, yours, &c.,

Wimpole-street, June 25th, 1880.

G. BUCKSTON BROWNE.

¹ See his work, p. 300.

ON A NEW METHOD OF EXCISING THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—I am sorry again to occupy your space with a letter on this subject, but Mr. Wright's letter of June 19th conveys an erroneous impression, which I am anxious to remove. When I claim that patients operated on by my method of preserving the ligamentum patellæ and the tissues in front of the joint uninjured, get earlier movement of the limb than those operated on in the ordinary way, I mean, that they get earlier power over the limb as a whole, and are able to get about sooner, and not that they have a movable joint, as Mr. Wright seems to understand.

In answer to his query, "Whether any movement of the knee-joint, after excision, is compatible with a stable support for the body?" I would say that I have seen two persons, one in my own practice and one in that of another surgeon, who, after excision, had movable knee-joints, with useful limbs, and were able to walk or run without mechanical aid. These cases, however, are quite exceptional, and the result of accident rather than design.

I am, Sir, your obedient servant,

WILLIAM KNIGHT TREVES, F.R.C.S.

Margate, June 26th, 1880.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—Just at present, while the administration of Chian turpentine is being advanced as a remedy for cancer, it seems only right to bring forward some evidence in its favour, and that, too, when its merits are being prejudiced, for the remedy as yet has not had a fair time of trial. The great difficulty in procuring the drug, and the substitution of a spurious article for it, are most likely to bring discredit on the remedy.

The following case which has come under my observation is worthy of record, and is one of great interest, as it bears directly on the subject in question.

A lady, aged forty-seven, of full habit, came under my care some months ago, suffering from symptoms that plainly told she was the victim of malignant disease of the womb. As no hope was given, it was thought advisable to see some specialist, and one of repute was accordingly called in; but the case was one that admitted of no doubt, and an opinion to this effect was expressed a second time,—“There was nothing to be done but to soothe, to give morphia, to the end.” Just about this time there was some mention made of the recent discovery of Professor Clay, and it was resolved to give his remedy a trial. The patient was then seen by him, now nearly ten weeks ago, and the Chian turpentine administered. After a little disappointment signs of improvement commenced to show themselves, and the result so far is most gratifying. Here, then, was a case of a most fatal kind, as to the nature of which there was no shadow of doubt. Under the influence of the true Chian turpentine this tumour, which was of a very formidable size, is now gradually diminishing—“melting away,” as described by Professor Clay, and the structure, which was formerly hard, that peculiar stony hardness *sui generis*, has now become softer, more resilient; in fact, more like uterine tissue.

I have no desire to make any comment, but wish to state the facts of the case just as they are.

I remain, Sir, yours truly,

Birmingham, June 17th, 1880. RICHARD DRURY, M.D.

To the Editor of THE LANCET.

SIR,—I have for some weeks been treating two cases of carcinoma uteri with Chian turpentine; in one case the pain has been neither so severe nor constant as formerly, but in neither case can I discover any arrest in the progress of the disease. The Chian turpentine I have been using was from the stock of a most respectable chemist, who assures me he has had it in his possession many years. It is only right to add that I submitted a sample to Professor Clay, which he pronounced to be spurious.

I am, Sir, yours, &c.,

J. STEWART.

Victoria House, West Hartlepool, June 28th, 1880.

DUBOISIN.

To the Editor of THE LANCET.

SIR,—Permit me to make some remarks on the great strength of the duboisin drops now employed—four grains to the fluid ounce. I have used the extract of duboisin for various forms of ophthalmic disease coming under my notice since the early part of 1877, when I first discovered its properties. I find two grains of crude extract of duboisin are equal in strength when applied to eyes to two grains of atropine sulphate dissolved each in the same bulk of water. The strongest preparation I use is ten grains of extract in an ounce of water. How much duboisin this represents I am unable to say, as I have not yet had a sample of duboisin for experiment, but think half a grain or less of it to the ounce will be ample for all ophthalmic purposes. There can be little danger of poisoning from duboisin I should think, as I never was able to kill a warm-blooded animal with it even in very large doses.

I trust in future duboisin for the eye will not be made of such great strength.

I am, Sir, yours truly,

Brisbane, April 16th, 1880.

J. BANCROFT, M.D.

NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—There is throughout this department a general thankfulness to you for the sound and fair manner in which its claims are being advocated by you, and a sense of confidence that although unaccountable delay is presented in the issue of the new warrant, yet, with THE LANCET in the van, there is a feeling of certainty of results. Your assertion of the principle that it is vain to look for candidates without stronger inducements and advantages in the whole course of an officer's service, comparatively with those of the army, will, it is hoped, not be disregarded in forthcoming arrangements. Last week you proved the different ways in which the senior officers of the “sister” services were recently treated, which still stands a scandal to Admiralty administration, admitted even by those who profited by the changes effected. The late Government certainly left the Department in a ruinous condition; but from the present some hope of respect to vested rights under service of the Crown may be entertained since the Prime Minister has declared his good-will towards even those of the licensed victuallers.

Your forecast of the Good-service Pensions to be given to the Army Medical Department has been realised—so it is said; and something equivalent must be looked for in the sister service, the Navy, where what good things of this kind there are are in the hands of officers whose breasts are not remarkable for medals or crosses, and whose services have never reached, in the majority, the higher responsibilities of the Department. In fact, in this respect Admiralty rules of selection are as paradoxical as they are inscrutable, and it is desirable you should keep a watchful eye on these rewards.

With the thanks of many, I am, Sir, yours truly,

SCRUTATOR.

PARIS.

(From our own Correspondent.)

AT a recent meeting of the Société de Chirurgie M. Verneuil showed a block of wood which he had removed from the rectum of a patient. The subject of M. Verneuil's communication is a woodcutter who has suffered for some years from dysentery, with incontinence of faecal matters. To remedy this he was in the habit of introducing into the bowel a plug of wood wrapped in a linen cloth, of which the ends were allowed to protrude. But on one occasion, having forgotten these appliances, a portion of a branch of a poplar, cut roughly conical with the axe, was made to serve the same purpose. Whilst at work this was suddenly felt to move upwards, and in spite of the patient's endeavour to arrest its progress, it disappeared entirely into the rectum. When consulted M. Verneuil was unable to detect any

foreign body by digital examination, but palpation revealed the existence of a hard lump, as it seemed, in the sigmoid flexure. He accordingly determined to open the abdominal cavity, to draw out the gut, and incise it as in the operation for gastrostomy, intending to put in carbolised sutures, and to return it if healthy, but to make an artificial anus if necessary. When, however, the abdomen was opened, it was ascertained that, instead of being in the sigmoid flexure, the wood had remained fixed in the upper part of the rectum. It was then found that it could be moved downwards, although with great difficulty, and when pressure was made upon it by M. Verneuil from above, M. Lucas-Championnière was able to reach it with the finger through the anus. After some unsuccessful endeavours to pierce and extract it with a gimlet and with forceps, a pince de Museux was disarticulated, and one of the blades used alternately as a lever and a tractor. To render this manœuvre more easy linear rectotomy was practised with the thermo-cautery, and after considerable trouble the block of wood was ultimately extracted. An examination of the rectum then showed that the difficulty of removal had been due to an extreme swelling of the mucous membrane to a hard oedema, which was no doubt caused by the obstacle placed in the way of the return circulation by the foreign body. Thanks to an antiseptic, or, to be more precise, a Listerian dressing, the subsequent progress of the case was most satisfactory.

The disturbances at the Medical Faculty of Montpellier seem to have come to an end for a time. Upon the re-opening of the school after its temporary closure the students determined upon a policy of obstruction, and in spite of the intervention of the civil and military authorities, they have managed to gain their cause. The Dean and the members of the *Conseil de permanence* having resigned, they have allowed lectures to be resumed; but unless the Government gives another example of "opportunism," some further trouble may be anticipated. In order to satisfy the demands of the students, the Ministry will have to appoint the instigator of these manifestations to the chair of natural history, and this after he has been threatened with condign punishment for his conduct in the matter by the Minister of Public Instruction.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Monday, in reply to Mr. O'Connor Power, Mr. Forster said he was in receipt of constant information as to the fever in county Mayo and the adjoining counties of Ireland. It was not, so far as he could learn, what was generally called "famine fever." It was not the kind of enteric fever that was such a great cause of death in the famine of 1847; it was a typhus fever. He heard different accounts of it; in some few cases it was passing off. So far as he could make out, it was not caused by want of food, but he thought a constant want of change of food might have accelerated the spread of the disease. In most of the cases he had heard of, the persons attacked had certainly not been in great distress, but some of them were. Undoubtedly it was a serious matter. The Government were doing the best in their power to meet it, and he believed they could meet it. They were sending the sick persons into hospitals, and ordering them better and more suitable food than they had heretofore been able to procure.

Sir Trevor Lawrence gave notice that on the second reading of the Vaccination Acts Amendment Bill he would move "That, in the opinion of this House, any measure which encourages and facilitates resistance to a law passed to protect the public from a loathsome and fatal disease, by enabling the contumacious to purchase themselves from under its operation, is dangerous to public health, injurious to public morals, and subversive of the first principles of legislation."

During the discussion of the Navy Estimates in Committee of Supply, on the vote of £47,584 to complete the sum for medical establishments at home and abroad, Mr. Gorst made some observations on the allowance for the medical establishment at the Island of Ascension, but the point of his argument was not clearly indicated, and the repeated references of the hon. member to the subject were greeted with laughter by the House. No reduction was proposed, and the vote was agreed to. On the vote of £56,363 to complete the sum necessary to defray expenses of medicines, medical

stores, &c., Sir A. Lusk objected to the allowance for carrying out the Contagious Diseases Acts, and moved to reduce the vote by £1000, but on being reminded by Mr. Shaw Lefevre that a Select Committee had just been reappointed on the subject, the hon. baronet withdrew the amendment, and the vote was agreed to.

The Medical Charities (Ireland) Bill was withdrawn.

On Tuesday Mr. Thornhill asked the Secretary of State for War why surgeon-majors of household cavalry are compelled to retire at the age of fifty-five without further promotion, whereas in other branches of the Service surgeon-majors at and after the age of fifty-five can attain higher rank, and their compulsory retirement does not take place till the age of sixty. Mr. Childers replied that the hon. member was under a misapprehension. All the surgeon-majors had to retire at fifty-five.

On Thursday Sir Harcourt Johnstone asked the Secretary of State for War why the Select Committee on the Contagious Diseases Acts is not yet appointed, a month having elapsed since the First Lord of the Treasury gave the assurance of its appointment. Mr. Childers said the Select Committee was reappointed some days ago, but there had been a difficulty in filling up two vacant places, which were rendered vacant in consequence of two of the former members not having been returned to this Parliament. Those places had been filled up that day, and he would put the names of the Committee on the paper that evening.

Obituary.

JOHN HARRISON, F.R.C.S.

MR. HARRISON, whose death took place on the 3rd ult. at Chester, at the age of seventy-two, was descended from an old Cheshire family. His father, the late Mr. George Harrison, occupied a leading position in Chester for more than half a century and was long associated as surgeon with the infirmary of the town. He also filled the civic chair for three different years before the passing of the Municipal Act. On the completion of his medical studies, the subject of the present notice qualified as a surgeon and commenced practice at Knutsford, but afterwards removed to Chester and filled the post of surgeon, and subsequently consulting surgeon, to the infirmary. In 1859 he was elected a Fellow of the Royal College of Surgeons. For more than eleven years he had been afflicted with a disease which he well knew would never be wholly shaken off, but his energy in no way slackened. During the last year he had been slowly but visibly failing; his activity, nevertheless, remained undiminished, and his manner lost none of its brightness; he worked on as the cherished friend and welcome adviser of the numerous circle of his patients. The severity of the late winter, however, at length asserted its power even over his strong will. Lightly clad, as was always his wont when driving rapidly even in the coldest weather, on an exceptionally bitter and windy day, he got thoroughly wet in a hailstorm. Notwithstanding a distressing cough he still struggled on, attending to every demand on his services, until increasing weakness obliged him at last to succumb. For some days he dressed himself as usual, but power for work no longer remained. The time for confinement to his room at last arrived, and in about eight weeks, gradually but surely, without physical pain, the sad end came, and the central spirit of a loving circle passed away. But his liberal charity, his open-handed hospitality and generous kindness, will ever be fresh in the memory of those who knew him.

WILLIAM JOY, M.R.C.S., L.S.A.

MR. JOY commenced practice at Dorking, where he resided about two years, when he removed to Northwold, in which village he practised for the long period of fifty-five years. Mr. Joy was a man with a strikingly handsome physique and particularly engaging manners, and by these qualities, combined with a sound knowledge of his profession, he had acquired quite an exceptional influence in the locality in which he spent a long and useful life. So great was his love for his profession that he was never known to take a holiday (except during an attack of typhoid fever thirty-five

years ago), as he was impressed with the idea that there was sufficient "change" in the daily routine of his professional duties. Mr. Joy was, in every sense of the term, a fine old English gentleman, and his death will be regretted not only by his large circle of patients, but by his medical brethren generally. He was in the active exercise of his profession till within a few days of his death, which resulted from an attack of pleuro-pneumonia on the 17th ult., in the eightieth year of his age.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen passed the required examination, and received the diploma in dental surgery, at a meeting of the Board of Examiners on the 24th of June:—

Ashby, Richard Desmond, Scarborough.
Bradshaw, Richard Giles, Streatham.
Holland, Joseph, Sloane-street S.W.
Humby, William Robinson, Newgate-street.
Parkinson, George W., M.R.C.S., Sackville-street.
Pedley, Fredrick Newland, Camden-road.
Smith, Alfred, Devonshire-road.

UNIVERSITY OF DURHAM.—The following gentlemen satisfied the Examiners and had their degrees conferred on June 22nd:—

DOCTOR OF MEDICINE.

Day, William White, L.R.C.P., M.R.C.S., L.S.A.
Ferne, Andrew, M.R.C.S., L.S.A.
Fie'den, Samuel, L.R.C.P., M.R.C.S.
Foster, John, F.R.C.S., L.S.A.
Moore, Milner Montgomery, L.R.C.P., M.R.C.S.
Price, Henry Elthington, M.B., L.R.C.P., M.R.C.S.
Steele, Charles, L.R.C.P., M.R.C.S.
Robinson, Arthur Henry, M.B., M.R.C.S.

MASTER IN SURGERY.

Hatton, George Stokes, M.R.C.S., L.S.A.
Lloyd, George Jordan, M.R.C.S., L.S.A.
Roué, William Barrett.
Seager, Herbert West, M.R.C.S.
Wills, Joseph Pearse Budgett.

BACHELOR OF MEDICINE.

Bedford, Walter George Augustus, M.R.C.S.
Calcott, James Thomas, M.R.C.S.
Cheetham, Walter Henry, M.R.C.S.
Coley, Frederic Collins, L.R.C.P., M.R.C.S.
Giles, Bernard Faraday, M.R.C.S., L.S.A.
Hatton, George Stokes, M.R.C.S., L.S.A.
Lloyd, George Jordan, M.R.C.S., L.S.A.
Mantle, Alfred, M.R.C.S., L.S.A.
Mears, William Pope, M.R.C.S., L.S.A.
Porter, William Smith, L.R.C.P., M.R.C.S.
Roué, William Barrett.
Seager, Herbert West, M.R.C.S.
Thornton, James Parsons, L.S.A.
Wills, Joseph Pearse Budgett.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 24th:—

Currah, George Ingersoll, Tottenham.
Goude, Herbert, Burton-road, Brixton.
Gould, William Robert, Westland Villa, Southsea.
Hoyle, William Evans, Newcastle-on-Tyne.
Shepherd, Timothy Arundel Jordan, St. Olive's Infirmary, Rotherhithe.
Whitworth, William, St. Agnes, Cornwall.

COLLEGE OF PHYSICIANS IN IRELAND.—At the June examinations the following obtained the licences in Medicine and Midwifery:—

MEDICINE.—Matthew Digan, George Digby, Isabella Margaret Foggo, Jane Russell Grant, Arthur Robert Harper, James Alfred Johnston, Henry Westenra Lentaigne, John Stephen McArdle, Sydney Pedler Morris, James O'Dwyer, Francis Allevyn Owgan, Henry J. C. Tweedy, Alice Vickery, John Warnock, Stewart Woodhouse.
MIDWIFERY.—Matthew Digan, George Digby, Isabella Margaret Foggo, Jane Russell Grant, Arthur Robert Harper, Hugh Harris, James Alfred Johnston, Henry Westenra Lentaigne, John Stephen McArdle, James O'Dwyer, Alice Vickery, John Warnock.

During the present-month the following have been admitted Members of the College:—

Edward Joseph Boulton, Sophia Jex Blake, James Murray, William Walter.

THE will of Dr. Joseph Nash has been proved under £8000.

MR. J. H. HUGHES, Public Vaccinator of the Ombersley district of Droitwich Union, has received (for the third time) the Government award for the efficient state of vaccination in his district.

A COMPANY has been formed in Cirencester to provide improved dwellings for the labouring classes in that town.

A NEW recreation ground for the inhabitants of Whitechapel was opened by the Prince of Wales on the 24th ult.

DR. ROBERT BIRD SELBY, of Port William, has been appointed a justice of the peace for the county of Wigtown.

THE salary of Dr. W. Sedgwick Saunders, medical officer of health for the City of London, has been increased from £700 to £900 a year.

MR. ALFRED GEORGE ROPER, late medical officer of the Workhouse of the Croydon Union, has been awarded a superannuation allowance of £100 per annum.

THE Queen's Hospital in Birmingham, for the first time in its history, is announced to be free from debt. This happy state of things is mainly due to the bazaar in aid of the hospital, recently held at the Town-hall, the profit from which was nearly £6000.

DR. JAMES PRESCOTT JOULE has received the Albert Medal from the Society of Arts "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording the engineer a sure guide in the application to science and industrial pursuits."

WOOD-PAVEMENT.—The Corporation of Dublin, at a meeting held this week, resolved that the thoroughfares about to be paved in that city should, opposite hospitals, places of worship, schools, &c., be laid with wood-pavement.

ST. MARY'S HOSPITAL.—The annual festival of this hospital was held at Willis's Rooms on the 30th ult., under the presidency of the Marquis of Huntly. The report read at the meeting set forth that the expenditure during the year had been £12,000, while the certain income was only £7000. Subscriptions to the amount of nearly £900 were announced.

METROPOLITAN FREE HOSPITAL.—The friends of this institution celebrated their annual festival at the Albion Tavern on Wednesday last. Mr. Alderman Cotton presided. It was announced in the course of the evening that the Committee contemplated building a new hospital for the sick and needy at a cost of £20,000. The appeal of the chairman resulted in an addition of £1170 to the funds of the hospital.

ST. THOMAS'S HOSPITAL.—The distribution of prizes took place on June 25th. The following are the names of the recipients:—

Summer Session, 1879.—First-year's student: College prize, £15, and certificate of honour, O. F. N. Treadwell. Second-year's students: College prize, £15, and certificate of honour, L. W. Bickle; college prize, £10, and certificate of honour, W. Wansbrough Jones.

Winter Session, 1879-80.—Entrance science scholarships: Scholarship, £60, and certificate of honour, R. M. Williams; scholarship, £40, and certificate of honour, B. Relton. First-year's students: The Wm. Tite Scholarship, £30, and certificate of honour, C. D. Green; college prize, £20, and certificate of honour, W. B. Tomson; college prize, £10, and certificate of honour, F. F. Caiger. Third-year's students: Second tenure of college scholarship, 40 guineas, college prize, £20, and certificates of honour, W. Wansbrough Jones. Anatomical students: G. F. Cooper, L. W. Bickle, W. T. Crick, certificates of honour. Prosectors: Prizes and certificates of honour, J. E. Dunn and F. H. Furnival; the Solly Medal and prize, £20, C. A. Ballance; the Cheselden Medal, W. A. Duncan; the Mead Medal, C. F. Coxwell. Resident accoucheurs: W. A. Battle, K. Takaki, C. E. Sheppard, C. A. Ballance, certificates of honour. House-surgeons: D. S. Davis, R. J. Williamson, R. P. Smith, C. E. Sheppard, certificates of honour. Assistant house-surgeons: R. J. Williamson, C. A. Ballance, A. Newsholme, J. R. Lunn, certificates of honour. House-physicians: W. W. Groome, R. P. Smith, J. Shaw, A. Newsholme, certificates of honour. Assistant house-physicians: R. P. Smith, D. S. Davis, J. Shaw, A. Newsholme, R. J. Williamson, G. S. Hatton, certificates of honour. The Treasurer's gold emdal, W. A. Duncan.

ARDWICK AND ANCOATS DISPENSARY.—The Committee of Management of this institution have issued an appeal to the public for assistance in utilising more fully the building erected for hospital purposes by means of the bequests of the late Miss Brackenbury. This building affords ample accommodation for out-patients, and hospital room for fifty in-patients. The scanty funds debarred the committee from opening for the most urgent cases more than six beds, since increased to nine. It is now proposed to raise the sum of £5000 to pay off the existing debt and put the hospital on a sound footing.

ATHLETICS.—The members of the United Hospital Athletic Club held a very successful meeting at the Enclosure, Stamford-bridge, on the 30th ult. Throwing the hammer, putting the shot, and foot-races of varying distances were gone through in a style, on the whole, highly creditable to the physical powers of the students who engaged in them. For the second year in succession, the challenge shield fell to St. Thomas's Hospital, by reason of the number of victories scored by their representative, Mr. H. M. Massey.—The first annual meeting of the St. Bartholomew's Hospital Athletic Club was held on the 17th ult. at the same place.

POPLAR HOSPITAL FOR ACCIDENTS.—The twenty-fifth annual festival in aid of the funds of this useful institution was held on the 27th ult. at the Freemasons' Tavern. The report stated that 4900 surgical and 5000 medical cases had been treated in the hospital during the past year. The deaths in the same period numbered 38, but of these 12 died on the day of admission, and 19 within a week. The work done in connexion with this charity, situated as it is among a population peculiarly exposed to accident, should commend it to the sympathies of all large employers of labour at the East-end. Subscriptions and donations to the amount of about £1600 were announced in the course of the evening.

CORK-STREET FEVER HOSPITAL, DUBLIN.—The committee, in their sixty-seventh annual report for the year ending 31st March last, regret that the small-pox wards during the past year have received, with occasional variations, a continuous weekly influx of patients, the cases at one time reaching 70, the daily average being 38. The total number of patients admitted during the year was 1083, as against 2151 in the previous twelve months. In continued fevers there was a considerable decrease. The cases of scarlatina were of a bad kind, and the death-rate reached 27.5 per cent. The total number of deaths was 186, or 17.58 per cent. of the admissions, of which 119 were caused by small-pox.

BEQUESTS ETC. TO MEDICAL CHARITIES.—The Fishmongers' Company have given 100 guineas to Queen Charlotte's Lying-in Hospital. The Home for Incurable Children has received £68 in aid of the building fund, being the proceeds of a private subscription ball at Willis's Rooms on the 14th ult. By the will of Mr. John Russell, of Cleasby, the Harrogate Bath Hospital and the York County Hospital have each become entitled to £500. Mr. Philip Twells bequeathed £2000 each to the Cancer Hospital, Fulham-road, and the City of London Hospital for Diseases of the Chest, and £1000 each to St. Bartholomew's Hospital and the Surgical Aid Society. The National Hospital for the Paralyzed and the Epileptic has received £400 from a "Friend to the Pension Fund" for the foundation of a "Bloomsbury" Pension of £15 per annum. Miss Parker, of Assloss, bequeathed £100 to the Kilmarnock Fever Hospital and Infirmary. The National Hospital for Consumption, &c., at Ventnor has received £90 under the will of Mr. George Scorer.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BAYNES, J., jun., F.C.S., F.I.C., F.R.M.S., has been appointed Public Analyst for the Borough of Beverley. £2 2s. per annum and fees.
BEVERHONDT, W. T. H., VON, M.R.C.S.E., L.R.C.P.Ed., has been appointed to the Sixth District of the York Union.
BRANNAGAN, H. C., L.R.C.P.Ed., has been appointed Assistant House-Surgeon to the Liverpool Infirmary for Children.
BYASS, W. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Dorchester District of the Wallingford Union.

CAITHNESS, J., M.D., C.M., has been appointed Medical Officer for the Llanrhaidr District of the Ruthin Union, vice E. Pierce, M.D., resigned. Also Medical Officer of Health for the same District.
COTTON, T., M.D., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer of the Eastern Division of Upper Holloway.
COWEN, P., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of the Western Division of Upper Holloway.
DICKINSON, T. V., L.R.C.P.L., M.R.C.S.E., has been appointed House-Physician to St. George's Hospital.
FEHRSON, F. J., M.B., C.M., has been appointed Medical Officer to the Dalston District of the Carlisle Union.
FOX, F., M.R.C.S.E., L.R.C.P.E., L.S.A.L., has been appointed Dental Surgeon to the Royal Hospital for Incurables, Putney, vice S. J. Tracy, M.R.C.S.E., L.R.C.P.E., resigned.
GRIFFITHS, W. H., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Hinckley Urban Sanitary District.
HAWKINS, F. D. C., M.R.C.S.E., has been appointed House-Surgeon to the Belgrave Hospital for Children, vice Bryden, resigned.
HENSMAN, A., L.R.C.P.Ed., L.F.P.S.G., M.R.C.S.E., has been appointed Aural Surgeon to the Middlesex Hospital.
HEWITSON, W. A., M.R.C.S.E., has been appointed Assistant-Surgeon to the Gateshead Dispensary, vice Dr. Potts, resigned.
HUGHES, Mr. T. W., has been appointed House-Surgeon to the Glasgow Royal Infirmary.
JENKINS, J. R., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Ruthin District of the Ruthin Union.
JOHNSTON, W., F.C.S., has been appointed Public Analyst for the Borough of King's Lynn. £5 5s. per annum, and 10s. 6d. for each analysis.
JONES, W. D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer of Health for the Llanfair District of the Ruthin Union.
MAIN, J. S., M.B., C.M., has been appointed Assistant Medical Officer to the Workhouse of the Chorlton Union.
PRICE, T., M.R.C.S.E., Medical Officer of the Cathedral District, has been appointed Medical Officer to the St. Michael District of the Manchester Union, vice J. Westmorland, M.R.C.S.E., resigned.
STRAHAN, S. A. K., M.D., has been appointed Assistant Medical Officer of the East Riding Asylum, vice H. G. James, L.R.C.P.Ed., deceased.
TINLEY, T., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer to the Fylingdales District of the Whitley Union.
VEITCH, A., M.B., C.M., has been appointed Assistant House-Surgeon to the Cumberland Infirmary.

Births, Marriages, and Deaths.

BIRTHS.

BRUCE.—On the 23rd ult., at Queen Anne-street, Cavendish-square, the wife of J. Mitchell Bruce, M.D., F.R.C.P., of a daughter.
FERGUSON.—On the 28th ult., at 43, Claremont square, N., the wife of W. E. Laing Fergusson, M.D., of a son (posthumous).
HORNER.—On the 28th ult., at The Gables, Tonbridge, the wife of Arthur Clayton Horner, M.R.C.S.E., of a daughter.
NICHOLSON.—On the 22nd ult., at Frankfurt-am-Main, the wife of G. de Poulton Nicholson, M.D., of a daughter.
WEIR.—On the 23rd ult., at St. Mungho's, Great Malvern, the wife of Archibald Weir, M.D., of a son.

MARRIAGES.

FORRESTER—JUSTICE.—On the 22nd ult., at St. Mary's, Cheltenham, by the Rev. James Badnall, B.A., Vicar of Endon, Staffordshire, James S. Forrester, Surveyor, Army Medical Department, only son of the late William Forrester, Surgeon-Major, Madras Army, to Marie Clarisse, eldest daughter of the late Rev. John Justice, Rector of Ightfield, Whitechurch, Shropshire.
HAMILL—MAUDE.—On the 29th ult., at the Wesleyan Chapel, Mansfield, by the Rev. C. W. L. Christien, assisted by the Rev. T. W. Johnstone, John Wilson Hamill, M.D., of Higher Broughton, Manchester, to Fanny Isabel, eldest daughter of James Maude, of The Woodlands, Mansfield.
HARDWICK—FARMER.—On the 22nd ult., at the Parish Church, Leeds, Maidstone, by the Rev. J. H. Dixon (brother-in-law of the bride), assisted by the Rev. A. P. Morris, Vicar, Frederick S. Hardwick, M.B., C.M., of Aberdeen, youngest son of Henry Hardwick, of Sullington, Sussex, to Emma, fifth daughter of the late William Farmer, of Battle Hall, Leeds, Kent.
NOLAN—SAVILL.—On the 29th ult., at the Church of the Holy Trinity, Paddington, by the Rev. John Stanley, M.A., William Nolan, B.A. M.D. Trin. Coll. Dub., Surgeon-Major, H.M. Bombay Army, son of the late John Nolan, Esq., M.D., of Athboy, co. Meath, Ireland, to Marion Frances, daughter of the late Thos. C. Savill, Esq., of Willow Cottage, Brixton-road, London. No cards.

DEATHS.

HOLROYDE.—On the 19th ult., at Clough House, Sydenham, Elkanah Holroyde, F.R.C.S.E., and J.P., late of the Clough, Bolton-by-Bowland, Yorks., and formerly of Manchester, in his 78th year.
PEARSE.—On the 24th ult., at Markham House, King's-road, Chelsea, Ellen Alice, wife of G. E. Legge Pearse, F.R.C.S., aged 27.
TAUNTON.—On the 24th ult., at her residence, Doughty-street, Guildford-street, Isabella, the widow of John Colley Taunton, M.R.C.S.E., of Hatton-garden, aged 76.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Lectures

ON SOME

RECENT INVESTIGATIONS

INTO THE

PATHOLOGY OF INFECTIVE AND
CONTAGIOUS DISEASES.*Delivered in connexion with the Brown Institution, at
the University of London, Dec. 1879,*

By W. S. GREENFIELD, M.D. LOND., F.R.C.P.,

PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTION,
ASSISTANT-PHYSICIAN AND LECTURER ON PATHOLOGICAL
ANATOMY TO ST. THOMAS'S HOSPITAL.

LECTURE III.—PART II.

It will be convenient here to advert to the facts in favour of the view that the anthrax bacillus is the cause of the disease (in the ordinary sense of the word), and not a mere concomitant. These facts have not all an equal value, and are not absolute proof, but so far as they go they are strongly in favour of this view. They may be summarised as follows:—

1. The constant presence during the disease of bacilli in the blood and organs in all classes of animals. Sometimes the number of bacilli is enormous, at others small; but even in these latter cases if the fluids are used for inoculation of certain of the lower animals, the disease is sure to be attended by their development in great number. I am aware that this constant presence of bacilli has been denied by some, especially by Hiller; but I am not aware of any facts in support of Hiller's view, and it is contrary to the almost universal experience of others. Moreover, Hiller's observations refer only to the blood.

2. When blood or any animal fluid containing these bacilli or their spores, and not altered by decomposition, is inoculated, it produces the disease together with the presence of bacilli; whereas, if the fluid inoculated does not contain any bacilli or spores, it is inert. The very few assertions to the contrary do not bear the test of critical examination. My own experiments have convinced me of the accuracy of the statement here made.

3. It has been commonly asserted that, when cultivated generation after generation in indifferent media, these bacilli still retain their power of causing the disease when inoculated in susceptible animals. This I was prepared to affirm until experiment had convinced me that it was not universally true. It may be true of some cultivating media, but is not so in those I have tried. Yet the results of cultivation are such as are scarcely to be explained on the hypothesis of diluted contagium, seeing that the seventh generation may certainly produce the disease.

Another set of arguments are derived from the comparison of the effect of agents which destroy the vitality of the fungus with the causes known to prevent the disease. Any conditions, whether compression or heat, putrefaction or antiseptics, which destroy the vitality of the fungus, destroy equally the power in the fluid of producing the disease. Decomposition has an especial effect, for as it proceeds the rapidity and certainty of the effects are proportionally diminished. If, for example, two animals are inoculated with the same quantity of the same material during hot weather, the one immediately after death, the other after exposure of the material to the air for a few hours, the production of fatal symptoms is in the latter very markedly delayed. Moreover, the persistence of the contagious property for a lengthened period is coincident with, and apparently dependent upon, the formation and persistence of the bacillus spore in a condition suitable for germination.

The arguments against this view have been fully stated by Dr. Timothy Lewis,¹ and as his work not only carries weight from the position of its author, but is likely to have a wide circulation, it is desirable that I should refer in some detail

to his views, and inquire how far they afford any ground against this view. In considering the evidence which has been adduced, showing that the virulence of septicous substance is not dependent on vegetable life, Dr. Lewis says:—"The question which naturally suggests itself is, whether sufficient evidence exists to show that inoculations can be effected with like material in the absence of such living organisms. The reply to this question, so far as anthracoid and cognate diseases are concerned, is distinctly in the affirmative. When Brauell published his paper in Virchow's *Archiv* in 1858, detailing his experiments to prove that splenic fever was an inoculable disease, he further stated the opinion that the organisms found in the blood could not be the carriers of the virus, seeing that blood not containing bacilli had been found to generate the disease. Bouley has arrived at a similar conclusion, and Böllinger, who has repeated Brauell and Bouley's experiments, has also shown that the disease may exist without the presence of bacilli in the blood, that such blood will induce the disease in other animals, and that even under such circumstances organisms may develop in the blood of the inoculated animal, and be detected during life as well as after death."

Now, let me place side by side with this Böllinger's own statement² as to these very experiments. He says: "Brauell produced anthrax in two fowls by inoculation with blood, which did not contain any rod-like bodies, while the blood of the inoculated animal showed them. From this he drew the deduction that these structures were neither the contagious material of the disease nor the necessary carriers of the same. Bouley failed to produce anthrax by inoculating with the blood of infected animals which contained no bacteria." He goes on to say: "It is easy to conceive that bacteria in the blood and organs of diseased animals may be easily overlooked on account of their smallness," and so on. "This I have proved experimentally and with the microscope, showing that in infectious blood of this kind, without bacteria, the germs of the latter are already present in the form of spherical bacteria. Indeed, I succeeded by the inoculation of diseased blood containing bacteria in producing true anthrax, in which the blood of the diseased animals contained no bacteria, although there were bacterial germs which after death developed outside of the body into characteristic cylindrical bacteria." And in further remarks on subsequent experiments by Brauell and others he clearly shows that in speaking of the absence of bacteria he is merely referring to the rod-shaped ones, allowing that the spherical spores or germs are present. I need only quote one more sentence to show how thoroughly Böllinger accepts the view that bacteria are the cause of the disease. "The tenacity of the anthrax poison—bacteria—is exceedingly great. In the dried state bacteria are able to preserve their virulence during months, and even many years."

Bouley also is now one of the most emphatic in the assertion that bacteridia are the cause of anthrax. In a recent paper he says, "Il faut accepter aujourd'hui comme une vérité absolument démontrée que le charbon procède de la bactériémie et de la bactériémie exclusivement, puisque les expériences de laboratoire les plus rigoureuses démontrent que sans elle ou sans spores, les inoculations de matières de provenance d'animaux charbonneuses demeurent toujours stériles, tandis que celles manifestent, au contraire, leur activité, quand les bactériémies leur sont associées. D'où cette conclusion nécessaire, qu'il n'y a pas de charbon possible sans bactériémies et que conséquemment, quand le charbon se manifeste quelque part, c'est que la bactériémie s'y trouve."³

Dr. Lewis also cites against the specificity of anthrax bacillus the fact that bacilli in some respects similar may occur in the blood of healthy rats a short time after death in India, where of course the temperature is especially favourable to their development. He mentions that in the blood of rats, killed by means of chloroform or asphyxiated, he found a few hours after death short rods, which were in some cases joined end to end, and which by cultivation lengthened into longer rods, and spore formation occurred in them. He describes the various phases which he observed, and concludes that these bacilli are identical with those observed in anthrax. I need not weary you with a detailed description of the observations which he adduces with the object of proving this. The facts I do not for a moment dispute; they are easy to observe for oneself; and I have often studied and watched similar changes occurring in decomposing

¹ On the Microscopic Organisms found in the Blood of Man and Animals, and their Relation to Disease. Calcutta. 1879.

² Loc. cit., p. 385.

³ Recueil de Méd. Vétérinaire, Nov. 15, 1879. Paris: Asselin.

Blood. But I think that no one who has studied cultivations of anthrax could mistake the bacilli which he figures for those cultivated from anthrax. Moreover, the whole of the arguments are pervaded by the obvious fallacy that because they are bacilli—that is, members of a genus—they are of the same species because they are found in the same fluid. That they are bacilli few could doubt; that they are anthrax bacilli, is quite another question. Anthrax bacilli do not, like these, grow in decomposing blood; moreover, these bacilli of putrefying blood, or the blood containing them, are almost entirely devoid of toxic properties, so far as my observations go; nor has Dr. Lewis given any evidence to the contrary. I may say the same with regard to the bacilli found in urine.

Whatever value these observations may have, they cannot for a moment outweigh the results of experiments verified by a number of independent observers who have found that material from animals dying of anthrax which contains either rods or spores reproduce the disease with the utmost certainty, whilst that which does not contain either is innocuous. On the other hand, these bacilli not derived from anthrax, however closely allied to, or even apparently identical with, the anthrax bacillus, do not when inoculated produce the disease, and in most cases are entirely innocuous.

And let me add that in order to control the results of observations on the organisms found in the blood and tissues in these diseases I have, from time to time, kept the bodies of animals which have either died a natural death or have been killed in various ways at different temperatures, and watched the organisms which developed in them.

ORIGIN AND SPREAD OF ANTHRAX.

Very naturally a large number of hypotheses have been suggested to account for the origin of the disease, or to explain its spread. Viewing it in the light of the better-known infectious diseases which affect man, we may well doubt whether it is not always carried by unsuspected ways of contagion. We cannot trace the source of every case or follow the spread of an epidemic of measles or scarlet fever; but from what we do know we feel little hesitation in affirming that the contagium has been carried from an antecedent case when we meet with an outbreak of the disease, however isolated or inexplicable that outbreak may be. In like manner, with splenic fever we are bound to exhaust all the known modes of contagion before we can be justified in believing that it is due to local conditions or processes.

Of the many ways in which contagium may be conveyed, few are so ready as that by way of food—for example, corn, hay, &c., which are so widely distributed, and can be followed only with so much difficulty. Some few facts which have come to light support the view that the disease may be thus conveyed. Experiment has shown that the ingestion of infected material may be speedily fatal, and that this is especially so when the food contains any hard or sharp particles which can cause abrasions of the mucous membrane. Now, seeing that the anthrax bacillus can be very readily cultivated in hay infusion or in malt, we see one way in which possibly contagion might be widely distributed. But the direct evidence in favour of this mode of transmission is as yet very inconclusive.

Let me now pass to the other modes of communication of the contagium. One very important question is the duration of the infection in the carcasses of animals which have died of the disease. It is extremely difficult to understand how it comes to pass that at certain periods animals become affected in certain localities, not only without any obvious source of contagion, but often in such isolated spots and under such conditions as seem almost to negative any possibility of direct contagion.⁴ But since it is well known that all parts of the carcasses of animals which have died from the disease are highly contagious, it is natural that the idea should have arisen that by some means the bodies of animals which have been buried in fields may infect the water, or even the pasturage, and then reproduce it. Hence the strictest regulations are in force in most countries as to the disposal of carcasses. In Prussia the carcasses must be buried two metres deep⁵; they may not be buried in swampy places, or near running water or springs, nor in the neighbourhood of dwellings; moreover, the spot

must be paved or covered with stone, in order to prevent vegetation, and to keep cattle from grazing upon it. In other countries the place must be fenced in for three years, and various devices adopted for preventing any possible spread of the contagium.

I have already mentioned certain facts which point to the belief that some forms of anthrax are especially liable to occur in marshy situations, and at certain seasons of the year, when the marsh lands begin to become dried by the increasing power of the sun. All experience in fact seems to point to the great influence possessed by certain localities in favouring the occurrence and persistence of the disease. It is found that in some meadows cases occur year after year, and it has been stated that those places where bodies of anthrax victims are interred cases have arisen again and again. With regard to the influence of locality, in an analogous if not identical disease, the Cape horse fever, we have very strong evidence of its marked tendency to arise amongst animals grazing in long grass on swampy ground, especially in spring and early summer. In face of these and other facts, two hypotheses might present themselves—one, that the disease originates in some miasm produced in these localities, so to speak, *de novo*, or developing in such a way under particular conditions as to give rise to the disease; or that the contagium is regenerated under these conditions of heat and moisture, and thus again becomes noxious. I need hardly remind you that if, as is now generally believed, the contagium consists in the bacillus anthracis, the spores of which can remain long dormant, and under favouring conditions start into life and activity, we should have a state of affairs fully concordant with those observed facts of the occurrence of the disease. For we know that these bacilli would find the conditions essential to vitality in moisture, warmth, and the presence of some vegetable pabulum analogous to our cultivating fluids of the laboratory.

But it may be asked, is the pre-existence of contagium revived under these conditions essential? May it not be that this bacillus can be derived from some other isomorphous bacillus, which acquires specific properties under cultivation in a particular soil or in peculiar conditions. So far as I am aware all the experiments hitherto made with the view of thus producing a contagium by cultivation of other bacilli have failed. The bacillus of hay infusion described by Cohn was naturally looked to as likely to be the organism in question, but several observers have tried, without success, to cultivate it with this object. I do not think, however, that we ought to draw any adverse conclusion from even a very large number of failures in such experiments, for success may be possible, and if it were so a step would have been taken in the solution of the mystery of contagia far exceeding any yet gained.⁶

But to return to the subject of infection from carcasses. Given the fact of existing spores, their persistence in the carcase or in the surrounding soil, and revivification under these favouring conditions would appear highly probable as a fresh source of disease.

Some experiments recently made by Professor Feser⁷ of the Munich Veterinary School have a very important bearing on this question of the duration of infection from the bodies of animals dying of splenic fever. The experiments were made especially with the view of deciding whether burial of the carcase was a sufficient precaution against the spread of the disease, or whether, as has been supposed, infection might spring up from the body after some time has elapsed. It had been suggested by Koch and others that the spores of the bacillus might be dormant and impregnate the earth around the carcase; that, when this was in a marshy or wet ground, they would be especially liable to be spread, and become the source of reinfection. And here arose the question, Whether these spores exist in the bacilli at the time of death, or were only developed afterwards? Koch suggested that, if the carcasses were buried about thirty feet deep in the ground, the temperature would be too low for the development of spores, implying that the bacilli alone existed in the body at the time of death; but, as I have shown,

⁴ Probably some of the cases of this kind which have been reported are cases of quarter-evil, a disease which has been confounded with anthrax, but which I hope to show is different.

⁵ With quicklime one metre.

⁶ Since delivering this lecture I have, I believe, established the converse proposition—viz., that the anthrax bacillus may be grown in cultivating fluids in successive generations, until it acquires an innocuous condition, though maintaining its power of germination and growth, and all its morphological characters. It may, therefore, be fairly suggested as possible that the anthrax bacillus is only a bacillus which has acquired special properties. But this suggestion is at present purely speculative.

⁷ Deutsche Zeitschrift für Thiermedizin.

spores may exist in the body, though not usually in the blood, at the time of death.

In a first series of experiments made in 1875,⁸ Feser found that the bodies of animals which had been buried for any length of time became innocuous. In his subsequent experiments he first of all disinterred the carcasses of animals which had died of anthrax some time before, and inoculated other animals from them.

In a first set of observations he disinterred two carcasses buried nearly a year before, and three others buried from four to nine days respectively, and after a very careful microscopic examination of the different parts, he inoculated other animals from them. In some cases the activity of the poison directly after death had been shown by inoculation of other animals from them, but, notwithstanding this, the experiments all proved absolutely ineffectual. It is noteworthy that Feser found in some of these carcasses some bacilli which precisely resembled in their shape the bacillus anthracis.

The second series of experiments were of even more interest, as they were destined to ascertain how long after death the carcass became innocuous, and what were the parts in which the poison lingered longest.

A number of animals having died of anthrax in the Munich Veterinary School as a result of inoculation experiments which were being carried on, fifteen animals were buried in two rows one over the other, so that two could be taken up at a time, the depth being about one yard and a half. Arrangements were made for ascertaining the temperature of the soil, and the condition as to humidity. The nature of the disease and the infective power of the carcass were in every case proved by direct experiment, and in several cases the animals were inoculated in a series one from another. The record of these cases brings out some striking facts as to the variety of modes in which the poison may be introduced. Thus, in these fifteen animals, in two the disease was communicated by inoculation of spleen, which had been frozen, in one some fluid from the spleen was placed in the conjunctival sac,⁹ causing death in less than three days, and in one the spleen given as food produced a fatal result in fifty-six hours. Five were inoculated with the blood, either fresh or frozen, and these were much less rapidly fatal, in one case five days elapsing before death. In two cases the flesh was given as food, and rapidly caused death, and in one the flesh was used for inoculation. But the most curious result was one obtained by inoculating a sheep with some urine of another sheep which died of the disease. In the urine a large number of bodies, resembling spores of bacillus, were found. The inoculated sheep lived nine days, and then died with tetanic symptoms. The spleen was found to be greatly enlarged, measuring six inches long and one inch thick, soft and dark, and containing many spores and short characteristic anthrax rods, which, when cultivated, grew into long rods, resembling bacillus anthracis. Feser thought them identical.

One other animal was infected by inhalation¹⁰ of spores derived from the carcass of another animal, and in its carcass were found very large quantities of short anthrax bacilli, some containing spores, and also free spores.

The carcasses of these animals were disinterred at periods varying from fourteen days to four months. A very elaborate microscopic examination was made of nearly all the tissues and organs, and inoculations were repeatedly made from them into other animals, but with one exception without the slightest result. The exception was in the case of the sheep buried only fourteen days. In the skin there were found spores which produced "characteristic anthrax organisms" by cultivation, but the inoculation of this material was ineffectual. Some muscle, however, rubbed down with water, was used for inoculating a horse with a fatal result in four days, with well-marked anthrax. In the exceptional instance, however, the temperature had been very low during the time of burial, and this result therefore accords with the general observation that very low temperatures are favourable to the preservation of the contagium.

There can be little doubt that these experiments go far to prove that even when under favourable conditions of warmth and moisture the carcasses of animals dying of the disease do not serve as centres for the propagation of anthrax, but become inert as soon as decomposition sets in.

Another set of observations seem also to show that, as had already been shown by others, vegetables of various kinds grown over the carcasses are perfectly harmless. Nor did inoculation with the soil around the body produce any result. It may therefore be safely assumed that some other mode of origin must be sought.

Notwithstanding the negative results of these experiments, it may yet be an open question whether in certain cases the contagium does not persist in the surrounding soil. The experiments of M. Pasteur just published, though far less extensive than those of Feser, can hardly be entirely set aside.

In these experiments M. Pasteur, with MM. Chamberland¹¹ and Roux, succeeded in reproducing anthrax by means of earth from the soil and around the carcass of an animal which had died of anthrax some months before, and also, as he states, cultivating anthrax bacillus in earth and infecting other earth from that over the carcass.

He first cultivated in 500 grammes of earth free from germs of bacteria, 20 drops of anthrax blood, and after thoroughly mixing the earth, he took 2 grammes of it and added it to 300 grammes of fresh earth; then from this he took 5 grammes and mixed it with 100 grammes of fresh earth, also free from bacteria. From the latter he took five grammes and was able to extract from it "germs of bacteria," of which he proved the virulence by inoculation of guinea-pigs. The time from the commencement of the experiments to the inoculation were from June to September. These earth cultivations, I may point out, only reached what one may call the second generation of earth cultivation.

The second series of experiments were made by burying the carcass of a sheep which had died of splenic fever, and ten months after (in May, 1879) he took earth from the superficial and deep layers of earth from the place of burial, and by inoculation of guinea-pigs with the superficial layer he produced charbon, whilst those from the deep layers caused septicæmia, which was, he says, of peculiar character.

These experiments prove conclusively, according to M. Pasteur, that the soil may be the means of preservation and cultivation of the germs and spores of bacteria, and that from them after some months the disease may be reproduced. The endemic prevalence of anthrax is thus, in his opinion, fully accounted for, the earth being infected by numerous cases. I must confess that I myself believe that, in spite of the elaborate precautions sometimes enforced to prevent the persistence and spread of the disease, there is sufficient evidence that the careless disposal of portions of the carcass—e.g., of parts of the skin and hair—is very common, and that this affords a sufficient explanation of the persistence and virulence of the disease.

One or two other points in relation to this disease remain to be mentioned, one the possibility of inoculating anthrax without causing a fatal result, and the protection conferred by this attack; the other the relation of the disease as it occurs in the lower animals to human disease.

In some experiments made last year by Dr. Sanderson and Mr. Duguid, but not yet published,¹² they found that when anthrax material, which had been transmitted through rodents, especially the guinea-pig, was inoculated in cows, the symptoms produced were analogous to those of anthrax, and very intense, but that in no case was the disease fatal. This was equally the case, whether the material was derived directly from the guinea-pig, or by means of cultivation in aqueous humour or hay infusion.

This observation seemed to me a very important one, for this reason, that if anthrax is, as is supposed by some, an acute specific fever, such inoculation of a modified contagium might be found to confer protection from subsequent attack. And, collaterally, if it did so confer protection, the marked analogy thus established with acute specific fevers would point to the possibility of the contagium of other acute specifics being of bacterial nature.

I have, therefore, repeated the experiment, as yet only with the inoculation through guinea-pigs, for I have not yet had any opportunity of further investigation with original material. The experiment was as follows. A heifer, previously in good health, having been kept under observation for nearly three weeks to ascertain its normal temperature, was inoculated with a small quantity of anthrax virus, which from some cause was ineffectual. The animal was therefore reinoculated with a larger quantity of material, the second cultivation in hay infusion, containing abundant spores, the

⁸ Gerlach's Archiv, Bd. iii., Hefte 5 und 6.

⁹ This I believe to be an unusual result, mere application to the conjunctiva rarely producing the disease.

¹⁰ Gerlach's Archiv, Bd. iii., S. 421-423.

¹¹ Bull. de l'Acad. de Médecine, Dec. 1879.

¹² They have since been published in the Journal of the Royal Agricultural Society, vol. i., 1880.

activity of which was at the same time tested by inoculation on a mouse. The course of the symptoms is best indicated by the chart which I have placed before you. For the first twenty-four hours no symptoms were observed; there was only very slight swelling at the seat of inoculation. On the morning of the second day—i.e., about forty hours after the inoculation—the rectal temperature was found to be 104° , having previously been 100° to 101° (the normal temperature). The animal was drowsy and stupid, and fed badly, but no rigor was observed, nor any very special symptoms. In the evening of the same day the temperature was lower (102.4°), but on the following day it rose to 106.4° F., and continued to vary between 105° and 107° for three days, during which time the animal was seriously ill, and at times appeared hardly likely to survive. On the eighth day, however, the temperature fell to 104° , and on the ninth to 101° , after which the animal speedily recovered, and continued perfectly well.

I was unable to discover any bacilli in the blood, but I do not attach any importance to this fact in proving that they did not exist. Inoculation with this blood, not containing bacilli, did not produce any symptoms in a rabbit.¹³

It remains to be seen whether this modified attack will confer any future protection on the animal.

ANTHRAX IN RELATION TO HUMAN DISEASE.

We know that in districts where anthrax is prevalent amongst cattle cases of malignant carbuncle appear in the human subject from time to time, especially in those engaged in dressing carcasses, or who have to do with the skins of the animals. I must not enter into the forms which this disease assumes in man, which have been very fully described by Böllinger,¹⁴ though I believe that several different diseases are included by him under the name of anthrax.

But I wish to point out the very great probability that some of the anomalous forms of pyæmia in the human subject, such as what is called *angina Ludovici*, for which no cause is discoverable during life or after death, may be due to contagion from this disease. One fact alone may serve as an illustration of the great facilities which exist for such contagion. In a case of anthrax, from which the material for some of my experiments was derived, the carcase had already been dressed for the London market. Some of the blood which had drained from it on to the floor was taken, and a guinea-pig inoculated with a very minute quantity. The animal died in twenty-seven hours, and its blood swarmed with bacilli. It was well known that the animal had died of splenic fever. I need hardly emphasise the urgent need of more thorough sanitary inspection. Moreover, there is some evidence that there exist forms of blood-poisoning in connexion with certain trades in this country which are really derived from anthrax, such as probably the "wool-sorter's disease," of which Dr. Bell of Bradford has just reported a case in which he found anthrax bacilli in the blood.¹⁵ (THE LANCET, Dec. 27th, 1879, p. 579). Similar diseases are known to occur in like occupations on the Continent. But these forms are as yet very little known; the two diseases in which there is a local lesion—viz., malignant pustule and so-called "internal anthrax"—being the best known in relation to human diseases.

I must now pass to the other anthracoid diseases which affect the lower animals.

¹³ Since the delivery of this lecture these experiments have been continued, and some of them have been detailed in the Journal of the Royal Agricultural Society (Part I. 1880). These, together with still further experiments not yet published, show that protection is conferred, which is great in degree and lasts a considerable time; and that this is true whether the poison is directly drawn from the guinea-pig or is cultivated, provided only that symptoms are produced by the first inoculation.

¹⁴ Ziemssen's Encyclopædia, vol. iii.

¹⁵ I may mention that I have been able to prove the identity of this disease with the splenic fever of cattle by recent experiments.

ON THE PATHOGENY OF LEAD PALSY.

By A. DE WATTEVILLE, M.A., B.Sc., M.R.C.S. ENG.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND
PARALYSIS, &c.

ONE of the most characteristic symptoms of saturnism, or lead-poisoning, is the paralysis of certain muscles of the forearm giving rise to the condition known as wrist-drop, or dropped hand. This condition is readily recognised by the fact that the patient cannot extend the hand upon the arm nor the first phalanges upon the metacarpal bones. The hand held out in the prone position hangs down helplessly; the only movements possible are a weak flexion and extension of the distal phalanges of the fingers and thumb. At first sight we have the spectacle offered by a paralysis of the musculo-spiral nerve from injury at the point of its emergence from between the fibres of the triceps; and the question naturally arises, To which of the possible causes is the paralysis due? If the patient presents the pathognomonic blue line along the gums—the peculiar aspect of saturnine anæmia; if he complains of colic and constipation, or if he is known to have been much exposed to the deleterious influence of the poison, then we naturally conclude that he suffers from lead palsy. But we must not forget, on the one hand, the possible concomitance of lead symptoms with a simple paralysis of the musculo-spiral from exposure to cold or slight pressure; nor, on the other hand, the possibility of a lead palsy unaccompanied by any of the other symptoms first mentioned. The patient may have been unconsciously poisoned by contaminated water, snuff, and the like, or by adulterated hair-dyes, toilet-powder, and other cosmetics, or even by medicinal use of acetate of lead, as I once observed in a case; and the first warning of the intoxication may be the paretic condition of the forearm. Now, in order to clear up our doubts, we are generally told to have recourse to two tests—that of the electrical reactions of the affected nerve and muscles, and that of the non-implication of the supinator longus. A discussion of the first will be best reserved for another opportunity; my object here is to consider the second, with a view of elucidating a point hitherto somewhat neglected in our text-books; I mean the pathogeny and localisation of lead paralysis. To Duchenne belongs the credit of having stated as a general axiom that in lead paralysis of the usual type the supinators always escape, though all the other muscles supplied by the musculo-spiral nerve are liable to be affected. The supinator longus, as he showed, is mainly a flexor of the forearm; and the method of ascertaining its condition is to tell the patient to flex the arm, whilst the observer resists the motion by holding the limb in a position midway between pronation and supination. Under these conditions the belly of the muscle, if unimpaired, starts prominently forward, and is readily seen and felt as a hard triangular mass filling up the bend of the elbow. We shall see, however, that this non-implication of the supinators among the muscles supplied by the musculo-spiral can no longer be held as a pathognomonic feature of lead paralysis; for it may also be observed in certain cases of circumscribed anterior cervical poliomyelitis—that is, of inflammation or sclerosis of certain portions of the anterior horn of grey matter in the cervical enlargement—and more especially of certain groups of the large multipolar or ganglionic cells therein contained.

It is certainly strange that such a phenomenon, the uniform protection of a muscle amidst the general paralysis and atrophy of all its companions, supplied by the very same nerve, should have been so long recognised without eliciting any attempts at an explanation. Yet this is what has happened; and it is only lately that E. Remak, in a valuable paper has propounded what appears to me to be a most satisfactory hypothesis. Most movements, such as flexion or extension of the several segments of a limb upon one another, although apparently very simple, require the co-operation of several muscles. The centres for these primitive associations are in the anterior grey matter of the cord, which contains the large cells just mentioned. These cells, arranged in groups, more or less independent physiologically and pathologically, are connected with the brain through

COOMBE LYING-IN HOSPITAL, DUBLIN.—The annual meeting of this institution was held recently, and from the report we learn that during the past year 680 patients were under treatment in the hospital, and 1953 attended in their confinements at their own homes. There were also 1754 attendances at the special dispensary for diseases peculiar to women, and 5448 at the general dispensary. Of the 680 intern patients 559 were in the labour wards, and 121 in the wards for diseases of women, the larger number of the latter having to undergo operations of a serious character. Since the enlargement of the hospital an increased expenditure has arisen, and a debt of some £700 has been incurred, which the Board hope shortly to discharge.

the "pyramidal" tracts of the antero-lateral columns of the cord (Flechsig). They give off in their turn the fibres to the anterior or motor roots which unite into the network of the cervical, lumbar, and sacral plexuses. The nerve-trunks issuing from these plexuses contain fibres derived from several of the roots, that is, from several nuclear spinal centres. It is on account of this peculiarity that when the lesion is localised in certain spots of the spinal grey matter, or in particular roots of the plexus, among the various muscles supplied by a single nerve, some are affected, whilst others escape. In the case of lead paralysis, for instance, the supinator longus escapes, because being a flexor of the forearm, its central nucleus must be more intimately connected with that of the other flexors of the forearm (brachialis anticus and biceps) than with that of the extensors of the hand. Now, since the very terms of the problem involve an elective affinity of lead for a special group of organs, I need only point out that the localisation of this group in the spinal cord gives a very satisfactory reason for the phenomenon under consideration. If we look at the independence of the spinal nucleus of the extensors as an anatomical and physiological fact, and to the common distribution of the peripheral nerve to one of the flexors as well as to the extensors as a mere contingent circumstance, the apparent anomaly is at once reduced to the reign of law.

These considerations have a plausibility which cannot be denied. They gain support, moreover, by a sort of *experimentum crucis* which nature herself has supplied for us. In a few rare cases of lead palsy the supinator has been found to be paralysed, but in those cases the other flexors (biceps and brachialis) have been found also affected. I must draw particular attention here to the great importance of a thorough electrical examination of the muscles, as it alone (especially in the earlier stages) will distinctly prove the existence of degenerative changes in muscles, the functions of which apparently are not materially impaired. The faradaic excitability may or may not be diminished; this depends upon the participation of the nerves in the process; but any qualitative departure from the normal galvanomuscular formula proves the existence of some interference in the so-called "trophic" influence of the cord, and generally heralds more serious troubles.

According to the theory, then, the flexors of the forearm and the extensors of the arm are each under the control of centres placed at different levels of the cord, through different roots of the plexus. There is a little experiment which will illustrate and confirm this view. If we stimulate the united fifth and sixth cervical roots at the point where the nervous bundle appears between the scapuli, we find that besides the deltoid and some scapular muscles, the biceps brachialis and supinator enter into contraction, the extensors of the hand and fingers remaining quiescent. Any one can convince himself of this fact by applying a moderate faradaic current, by means of a small pointed electrode, to a point near the posterior edge of the sterno-mastoid, and about a couple of inches above the clavicle. I had the opportunity, some years ago, of seeing a case in which owing to a lesion of the fifth and sixth roots, these very muscles were paralysed, and several such have been lately described. I think we may, in presence of this cumulative evidence, safely assume that the primary lesion in lead paralysis involves, if not the spinal centres themselves, at least the roots or cords above the points where these intermingle in the plexus to form the several nerves of the limb. The latter alternative need not detain us long; for though we may not be able absolutely to disprove it, yet every analogy is opposed to its probability. At any rate the most careful investigations have shown that, even in cases where the nerves were largely implicated in the process of degeneration, the roots themselves were healthy.

Before going any further, I may say a word about the theory of a muscular origin of lead-paralysis, which has from time to time found supporters. Some of their arguments, such as the supposed accumulation of lead in the muscles, and changes in the local circulation, have been demolished by actual demonstration; others clash with the recognised immunity of the supinator longus; others, finally, have been derived from experimental data, totally at variance with the conditions prevailing in clinical observation. This theory need not, then, detain us long.

An objection to the spinal localisation of lead palsy, however, remains to be answered. How is it that there are next to no cases on record where any pathological change has been noted in the cord, even in advanced saturnism? May

I not suggest that the circumscribed, and perhaps but slight, lesion—which is all our theory would imply—has hitherto escaped attention? A thorough systematic examination of the cord is difficult and comparatively rarely carried out. But even should ulterior researches prove negative, is it necessary to assume a gross organic lesion of a nerve-centre to account for peripheral changes? In the case of lead paralysis we have primarily symptoms of diminished trophic influence of the cord, followed by loss of power. Why should not lead act here as it does in the production of hemianæsthesia—act not as a destroyer of tissue, but a modifier of nutrition, or molecular organisation, leading to suspension of function? Other poisons, such as mercury and arsenic, may give rise to nervous symptoms without producing any evident lesions to explain them. Again, in Landry's ascending paralysis, almost every activity of the cord is abolished, and yet it still ranks as a so-called "functional" disease, and it is not unlikely that in "general neuritis" a similar "functional" disturbance of the spinal grey matter is the origin of the peripheral changes. Whatever be the worth of these suggestions, we have with reference to the pathogeny of lead paralysis to accept the greater of two probabilities—to choose (a) between the toxic effect of the metal manifesting itself by interfering through a hitherto unexplained process with the functions of a certain independent spinal centre, and (b) saturnism, setting up a peculiar localised neuritis, strictly limited to a certain number of motor fibres of the same nerve, picking out precisely those originating from that centre. The latter alternative, it will be granted, has some features which make its acceptance far from easy. But I need not dwell on them, and will conclude by saying a few words on the striking resemblance between paralysis due to lead and that due to an organic disease of the anterior horn of grey matter, or poliomyelitis, such as is observed in infantile paralysis and the corresponding disease, acute or chronic, of the adult. Thus I have witnessed a case of wrist-drop, which, to use Professor Erb's own words, "nothing but the impossibility of tracing a history of lead poisoning made me exclude this diagnosis and assume the existence of a circumscribed patch of anterior poliomyelitis." Again, we have just seen that when lead affects the supinator, the other flexors are also affected, usually along with the deltoid and some scapular muscles, the reason for this distribution being the close relation of the nuclear centres of these muscles (supplied from the fifth and sixth roots). This distribution is far from uncommon in cases of poliomyelitis. Quite lately I again had the opportunity of observing it in a case of infantile paralysis, and in one of chronic poliomyelitis in an adult. In the latter, especially, the power of flexing the arm was absolutely lost; the faradaic and galvanic excitability of the muscles involved was almost extinct. The other muscles of the arm and forearm, though beginning to be implicated in the downward progress of the disease, had preserved a very fair amount of power and electrical excitability. In the somewhat rare cases where lead paralysis manifests itself among the leg muscles, its distribution is precisely the same as that which obtains in poliomyelitis. When the peroneal and extensor muscles are affected, the tibialis anticus is usually found healthy. When the latter is involved then the extensors of the leg (rectus and triceps femoris) also give signs of degeneration. The tibialis anticus, in fact, reminds one of the supinator longus by its immunity among the muscles supplied by the peroneal nerve; it probably derives its nervous supply from the fourth lumbar root, and its nucleus is in close anatomical relation with those of the extensors of the leg. Again, the great clinical resemblance between general lead paralysis and acute spinal paralysis is highly suggestive of a pathogenic unity between the two processes; and Vulpian has lately shown that progressive muscular atrophy—a disease, by the way generally considered spinal notwithstanding the somewhat conflicting data of morbid anatomy—may be occasionally traced to the influence of saturnism.

As a rule, progressive muscular atrophy is more erratic in its localisations than chronic poliomyelitis; but here also it has been my good fortune to meet with a considerable parallelism between the idiopathic and the saturnine process. In two typical cases—one of severe lead palsy, the other of progressive muscular atrophy involving the right forearm—there was a striking analogy between the muscles involved. In both the extensors of the wrist and fingers (with immunity of the supinators), the small muscles of the hand, and the long flexors of the fingers were affected. In

the case of progressive atrophy the long flexors were obviously wasted, in that of lead paralysis less so, but the remarkably feeble grasp of the patient made me suspect something beyond the loss of the antagonistic effect of the extensors, and to my surprise I found the flexors flabby and yielding the characteristic reactions of degenerative change. This observation, as far as I am aware, is the first of its kind. The dictum, probably, that in lead palsy the flexors are never affected, has diverted the attention of observers from their electrical condition, the testing of which, it must be added, offers some difficulties. As it is, my observation curiously tallies with a statement of Remak, who observes, that owing to the proximity and physiological connexions of the spinal centres of the interossei and long flexors of the fingers, these muscles are often found involved together, and that when, as happens in certain cases of saturnism, the former are paralysed, the latter, by analogy, might be expected to show signs of atrophy.

The cumulative evidence for a spinal origin of lead paralysis is, I take it, almost irresistible, and then the precise localisation of the disease offers no difficulty. We know from observations of cervical pachymeningitis that the eighth cervical and first dorsal roots supply mainly the flexors of the fingers and small muscles of the hand; the fifth and sixth cervical roots have the distribution mentioned above—viz., the shoulder muscles and flexors of the arm. There remains only the seventh cervical; it is therefore in the anterior group of large cells giving origin to this root that we must look for the primary pathological changes, whatever they be, molar or molecular, of the typical saturnine wrist-drop. Whether our therapeutical resources will benefit by our increased theoretical knowledge of the disease remains to be seen. Hitherto, besides the orthodox administration of iodide of potassium, electrification of the affected muscles has been our sheet-anchor. A more localised, central application of the continuous current in *loco morbi*, combined with peripheral stimulation, might fairly be tried. But on this point I speak with all reserve, knowing how much the credit of electro-therapeutics has been impaired by the premature statements of narrow-minded enthusiasts.

CAUTIONS AND SAFEGUARDS ABOUT THE CLIMATE OF THE ENGADINE.

By JOHN KENT SPENDER, M.D. LOND.

THE precept "go abroad" is much in fashion with doctors, and obedience to it is not less willingly yielded by patients. The medical injunction is reinforced by considerations of novelty, scenery, art, and aesthetics generally; pecuniary economy is quite out of the question now, for time and distance require a long and strong purse, and Continental prices often rival in grandeur those of the most favoured spots in Great Britain and Ireland. To youth and health the charm of foreign travel knows no abatement, nor are we so cynical as to wish it to be otherwise. But when the first bloom of health and youth is gone, and some of the weariness of ripper age begins to be felt, new conditions are submitted to medical judgment, and nothing requires more careful forethought than advice about "change of air." A man who goes to Switzerland ought to take health in his hand, instead of searching for health when he is there. We confuse the respective benefits of mind and of body, and hastily infer that because a jaded mind is refreshed by Alpine wonders, a tired body is to be renovated by constant climbing, long excursions, and exposure to sudden thermometric and hygrometric changes. But if a body be diseased as well as tired, how much less capable is it of undergoing the discipline of the ordinary tourist, who is unhappy when not moving about, and who craves incessantly for new worlds and new skies!

I plead, therefore, that "change of air" is a desideratum not always best gratified by going abroad, and that for several reasons. 1. The fatigue of the journey many of the most popular Continental spas. 2. Excessive atmospheric heat, often alternating with violent thunderstorms

and unexpected chills. 3. The incessant noise and want of homely seclusion at most of the large foreign hotels, to say nothing of the absence of many domestic comforts prized by invalids. 4. Defective sanitation is still the great European blot, sometimes fouling the places which are most lavishly dowered with natural beauty. How serious it is that a person who travels in quest of health may not only fail in his mission, but may bring home a fresh and perhaps fatal disease.¹ The rule ought to be absolute that before a medical man advises a patient to go to a foreign health resort (whether inland or by the sea), he should go there himself first and be satisfied that it possesses the telluric and atmospheric qualities for which he recommends it. Second-hand knowledge on these matters has had very mischievous results; but whenever we are obliged (as must be sometimes the case) to consult the reports of others, the accounts given in local guide-books and the like must not always be trusted without some confirmation from disinterested sources. With these preliminary words I pass to the special subject of this short paper, which is to offer a few cautions about the climate of the Engadine, and to describe the conditions and limitations within which its salutary properties may be enjoyed.

The Engadine (Oeni-Gadina, Upper Valley of the Inn) has been so often described that I need say very little here on its geography. It is situated in the S.E. of Switzerland; it is about fifty-seven miles in length, seldom more than a mile in breadth, and runs from S.W. to N.E. Even at the upper end, the source of the Inn, it is a true valley, inasmuch as it is flanked by lofty mountains; but here it is no less than 5500 feet above the sea-level, and gradually slopes downwards with the course of the Inn to Martinsbruck, which is the boundary between Switzerland and Tyrol, and where the elevation is somewhat more than 3000 feet. From these data the climate can be easily inferred. It is as inclement as that of the north of Sweden or of Finland: the cultivation of corn is almost unknown, and tillage generally is very backward. The mean temperature of Pontresina for the whole year is only 34.7° (Fahr.); that of the three summer months (June, July, and August) is about 50°. The meteorological station is 6001 feet (1829 metres) above the sea. In summer the weather is never sultry, sometimes decidedly cold; the highest temperature ever recorded is 70.77°, but even 70° is rarely approached, and at dawn of day the mercury is sometimes nearly at freezing-point in July and August.² I do not speak of the meteorological curiosities of this region at other times of the year, because they do not practically concern British travellers.

The diminished pressure of the air is an important medical feature in the climate of the Upper Engadine. It is indicated by the physical phenomena of the mean height of the barometer being only 24.10 inches, and by water boiling at 202 degrees: hence the atmospheric pressure is fully one-fifth less than at the seaside. The air is proportionately rarefied, and being so constantly free from vapour, solar light and heat are much intensified. There is so little obstruction to the sun's rays that they beat down with uncommon fierceness on man and beast, and render a protection to the head always necessary in the middle of the day. I have never heard to what point the black-bulb thermometer would rise on exposure to the sun; but this I can testify, that there is a feeling of *stifling heat* in the air on clear days, owing to the heated condition of all terrestrial objects. And the difference of temperature between shade and sunshine is much greater than in the lowlands.

Now I wish to draw special attention to the two sources of danger which lie in ambush for delicate travellers whose main business is to recover health. (a) The first peril is the extreme range of temperature between day and night. Beneath unclouded skies radiation goes on without check or stint. Quite early in the afternoon Silvaplana is thrown into shade by the sun declining behind the mountainous slopes of the Julier; shade deepens into dusk, and dusk into night, and July is metamorphosed into October. A man who takes a stroll between 9 and 10 in the evening without a thick wrap over his shoulders is an adventurer who will probably pay his penalty, however rude his

¹ There is a fashion now in favour of roaming in Brittany, and in the last (June) number of the Magazine of Art there is an illustrated sketch of the archaeological attractions of Morlaix. Not a word of caution is written of the pestiferous qualities of that quaint old town, where there is enough fever and diarrhoea to satisfy the most enterprising pathologist, and as many stench as at St. Malo.

² I take these details from Dr. J. M. Ludwig's excellent handbook to Pontresina and its neighbourhood, fourth edition, 1879.

strength may be. How is the traveller to ventilate his bedroom at night? There is perhaps no fire-place, and if he open the casement but a crack the almost freezing air will enter the chamber, and with an inrush proportionate to the disparity of the external and internal temperature. The alternatives, therefore, are suffocation or chill. (b) The other danger is the great variation in the relative humidity of the air. In the morning and in the evening the humidity amounts now and then to 80 or 90 per cent.; early in the afternoon it may fall to 30, or even 25, per cent., and the atmosphere is said to be so dry during the winter months that meat may be preserved solely by its influence for several weeks at a time.

Now a simple comparison will show the advantage of the climate of the north of Sweden and Norway during the height of summer. If the sun has much less power by reason of its lower altitude, it shines continuously for a few weeks, and there is no night at all. So there are none of the fierce contrasts of more southern regions, where the brilliant sunshine of fifteen or sixteen hours is balanced by the rapid radiation during the hours of darkness. As a matter of poetry, and as favouring sleep, it may be desirable to have more night and less day; as a matter of physiological physics it is far better to have the solar influence distributed more evenly over the twenty-four hours, and for the body to endure less thermometric extremes.

During the nine days which I spent in the Engadine last summer (Aug. 12th to the 21st) the weather was variable. Five days were absolutely cloudless; two were showery; two were very rainy, with much lightning and thunder. The few days (Aug. 19th to the 22nd) which were so bad in England were very fine in most parts of Switzerland. A thunderstorm in the Engadine may come on suddenly; in a few minutes the temperature runs down fast, and the air feels damp and chilly, like Scotland or the south-west of Ireland. Dr. J. M. Ludwig's statistics are by no means favourable to the doctrine that the climate is (on the whole) a rainless one, as the number of days on which there is "more or less rain" from June to August (inclusive) is quite equal to what we have during an average summer at home. September is generally the least humid summer month. But the unexpected changes from fair to foul and foul to fair are very trying to an invalid. He may indeed guard against them by narrowly watching the barometer; but where is the convalescent who will systematically take so much trouble? Both at Pontresina and at St. Moritz there are plenty of "oracles" who can be wise after an event, and whose philosophy consists in telling certain people that they ought not to have come there at all. I do not wish to dwell on my own miseries, and how I was confined to bed for four days at St. Moritz by acute pyrexial lumbago and sciatica; but I feel entitled to warn rheumatic and gouty folk *not* to "try the Engadine."

From a health point of view, the difficulty of Switzerland is in its "ups and downs," the close heat of the valleys and the meteorological treachery of the "passes," where, at a height of only 6000 feet, deep snow in August is not very uncommon (as in 1876). But the point I wish to emphasise is that, however high above the sea a valley may be, *it is still a valley if shut in by mountains*, and therefore cannot have those health-giving properties which belong, for instance, to a Yorkshire moor or to the sea-level itself. An English or Scotch moor may seem to the artistic eye rather dreary, but Jean Ingelow's picturesque line—

"An empty sky, a world of heather"—

conveys the idea of *openness* and freedom from barriers which is truly refreshing. To be on tolerably high ground, with nothing to check a full sweep of the horizon, suggests all the winds of heaven blowing freely about, plenty of ozone, and a positive deliverance from organic poisons and contaminations. But here is the oddity of foreign ways, that the most frequented spas or systems of baths are down in hollow basins or caverns, hedged round by alps or steep fir-clad precipices. A traveller bound for the Engadine will probably stop at Ragatz, and wind his way by the side of the "impetuous Tamina" to the historic baths of Pfäfers, buried in the bottom of a dark gorge, where even the midsummer sun can shine for only a few hours in the middle of the day. The Tarasp Spa, in the Lower Engadine, approached by miles of the loveliest scenery, and a rendezvous of sick people from all parts of Europe, is situated on the level of the Inn itself; the direct solar heat is intense, and the grand enclosing mountains hinder the proper circulation of air. I might

enumerate several instances of a similar kind in Germany. What comparison, then, is there between these grilling places and our own breezy uplands and our glorious splashing seas?

I dispute not Dr. Ludwig's assertion, that the climate of the Engadine has some prime qualities, and that it may be greatly beneficial in some "nervous disorders consequent on severe illness or excessive exertion"; during recovery from some acute diseases; and as an antidote to certain grave constitutional conditions. But let it be remembered that we are dealing with a two-edged weapon, which may wound as well as heal. Exposure to storms, insufficient dress, and too long walks, are the snares which beset the invalid, and are more likely to entrap him here because the whole country is a paragon of beauty, and the air is nectar itself. To the wearied brain-worker who finds rest in the variety of outward objects and in the mere movement of travel, I say, Go to the Engadine and enjoy it to the full. But do not delay, as the valley is quickly losing its pristine innocence; and for noise and gaiety some quarters of it will soon rival Brighton and Scarborough. Nature, too, has not been entirely kind; for in 1878 the woods of the Upper Engadine were visited by a troublesome guest. A moth laid its eggs on the smallest twigs of the conifers; the caterpillars, when they came out, ate off the needles, so that the trees looked red instead of green. And the result of this devastation last summer was, that there had been a loss of thousands of larches and cembra pines.

Bath, June 9th, 1880.

FAT-EMBOLISM IN FRACTURES.

WITH NOTES OF A CASE.

By F. A. SOUTHAM, M.A. OXON., F.R.C.S.,

MEDICAL AND SURGICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY.

THE subject of fatty embolism in cases of fracture, though it has attracted considerable attention on the Continent, has not hitherto been much noticed in this country, and I therefore think that the particulars of a case in which this condition was found to be present after death may not be without interest to the readers of THE LANCET.

A man, aged forty years, was admitted into the Manchester Royal Infirmary about 11 A.M. on Feb. 27th, suffering from a severe compound comminuted fracture of the bones of both legs about their lower third, caused by a railway waggon passing over them. Amputation of both legs below the knee was performed antiseptically immediately after admission by Mr. Heath. The patient bore the operation very well, and was kept under the influence of opium afterwards. The evening temperature registered 101.2°. He passed a good night and expressed himself as feeling very comfortable the following morning. Temperature 103°; pulse 132; his general condition appearing altogether very satisfactory considering the severe injuries he had received. About 3 P.M., however, the same afternoon a sudden change was observed; he became very restless and excited, his countenance of a somewhat dusky hue, with increased frequency of the pulse and respiration; no rigors nor marked dyspnoea were observed; later on he became delirious and his condition was quite hopeless. At 9 P.M. the temperature was 105°, the pulse too quick and weak to be counted. There was slight discoloration of the integuments of the stumps discernible above the dressings, and a faint odour was perceptible, showing that putrefactive changes had been set up in spite of the antiseptic measures employed in the operation. At 10 P.M. death took place. (Strange to say, both the patient's arms had been amputated above the elbows about nine years previously for injuries of a similar character.) A post-mortem examination was made by Dr. Bradshaw, pathologist to the hospital, but no morbid changes of any importance were perceptible to the naked eye. As from the nature of the injuries it was thought not improbable that fatty embolism of the lungs might be

present, a portion of those organs was kept for microscopic examination.

Sections of the lung were afterwards made by Dr. Bradshaw, and on staining them with a solution of osmic acid, the presence of fatty matter in the capillaries and minute

Section of lung treated with osmic acid, showing the vessels in the alveolar walls plugged with particles of fatty matter, which is stained black. ($\times 150$.)

arteries was at once detected by him. It presented itself as minute globules and irregular masses of various sizes and shapes completely blocking up the vessels. Unfortunately none of the other organs were kept for microscopic examination.

In this case it is difficult to say whether the fatal result must be attributed to the plugging of the minute vessels of the lungs by particles of fat, or whether it was due to a condition of acute septicæmia which so often suddenly sets in about the middle or end of the second day after the receipt of a severe injury, and which usually causes death in the course of a few hours. The symptoms of this acute form of blood-poisoning are described by Billroth as "collapse with cyanosis" suddenly setting in. "The patients appear as if suddenly poisoned after having perhaps felt quite well during the first twenty-four hours after the operation." In this case death was at first attributed to this latter condition, and the rapid rise of temperature to 105° , along with the state of both stumps, would certainly be strong arguments in favour of it. On the other hand, the fatal result may have been due to the plugging of the vessels of the lungs, for the clinical symptoms of fatty embolism, as hitherto described—viz., collapse, more or less sudden, accompanied by the general signs of shock, though usually coming on shortly after the receipt of the injury, may be delayed for twenty-four hours or even two or three days, the patient in the meantime appearing comparatively well. The taking up of the fat by the open vessels from the medulla of the bone begins immediately after the receipt of the injury, and where an interval of time elapses before the symptoms of pulmonary embolism suddenly appear, may it not be explained on the supposition that the fatty matter, temporarily arrested or stranded in the vessels in the neighbourhood of the wound, is, after a time, when the patient has recovered from the shock of the injury, and when reaction has set in, suddenly carried on with the blood-stream under the influence of the renewed circulation, until it is arrested in the vessels of the lungs?

Fatty embolism of the lungs, though most commonly observed in compound, has also been found in cases of simple fracture. A very interesting case was reported by Dr. Hamilton, of Edinburgh (*Brit. Med. Journal*, October, 1877), where this condition was found in a patient after rupture of a fatty liver, and it is not at all improbable that it is present to a greater or less degree when life is suddenly terminated by severe injuries, and especially in those cases attended by lesions of the osseous system.

In a paper published by Prof. Sanders and Dr. Hamilton, which appeared in the *Edinburgh Medical Journal* last year, particulars are given of a case of diabetic coma, in which, after death, fatty embolism of the lungs and also of the kidneys was observed. In the former organs, "not only were the small vessels plugged with the oily emboli, but in the larger and middle-sized arteries the oil-globules spread themselves out on the wall of the vessels and adhered to it." A peculiar condition of the blood was observed, and this has also been found to exist in other cases of a similar

nature. It presented the characteristic odour of acetone, and, on standing, a milk-white stratum collected on its upper surface, which on microscopic examination was found to consist of "a fine chyle-like emulsion of oil, the globules being minutely divided."

Though numerous cases have been described on the Continent, these are, as far as I am aware, the only two hitherto recorded in this country in which on post-mortem examination fat-embolism of the lungs has been found to exist.

The most recent researches on the subject of fat-embolism are, I believe, those of Wiener (*Arch. für Experim. Path.*, Vol. xi.), who made a number of experiments on different animals (dogs, rabbits, frogs), injecting pure olive oil into the serous cavities, veins, and subcutaneous tissue.

In a first series of experiments, he found that when oil was injected into the pleura or peritoneal cavity, extensive fat-embolism was found in the capillaries of the lungs in the course of a few hours. When the oil was injected into the subcutaneous tissue the pulmonary embolism, which was much more limited, did not appear until the third or fourth day; this he proved was due to the intervention of the lymphatic glands, which retained and probably at the same time partly emulsified it. The conclusion he draws from these results is that the fatty matter can be taken up not only by the veins (as was formerly supposed), but also by the lymphatics, even when they are intact, and that the intervention of lymphatic glands does not, as has been suggested, altogether prevent fat-embolism in the lungs.

In a second series of experiments Wiener found that changes in the lungs, consisting of ecchymoses and pulmonary oedema, due to the presence of fat-emboli, were only present when very extensive fat-embolism existed; hence he infers that as a rule fat-embolism is perfectly harmless and does not give rise to the symptoms of dyspnoea, convulsions, shock, &c., which have been observed in man in cases of fat-embolism occurring after fractures. This view is supported by the fact that many of the animals experimented upon remained perfectly well, and yet when killed fifteen to twenty days after the injection, showed extensive fat-embolism of the lungs.

In a further series of experiments with respect to the ultimate destruction of the fatty emboli, he found that this condition was present in many organs, but especially in the brain and kidneys; few, if any, emboli were found in the liver, as in this organ the fatty matter seems to pass very readily through the walls of the capillaries, becoming deposited in the form of large fat-drops in the hepatic cells. In the kidneys the fat is found in the glomeruli, in the vasa afferentia, and in the tubuli themselves; from these facts, coupled with the appearance of large masses of fat in the urine soon after the injection, Wiener infers that the greater portion of the fat injected is carried with the blood into the kidneys, where it is eliminated in the glomeruli, and passes away with the urine. At the same time no doubt another portion, by becoming emulsified, is taken up by the lymphatics. Finally, he found that in moderately strong dogs all the fat injected appeared to become eliminated in from three to four weeks.

As illustrative of the facts observed by Wiener with respect to the part played by the liver in cases of fat-embolism, I may refer to a case of diabetic coma which was a short time ago in the Manchester Infirmary, under the care of Dr. Dreschfeld, and in which, both before and after death, the blood was found to contain large quantities of fatty matter. On post-mortem examination, Dr. Dreschfeld found no evidence of fat-embolism in the lungs nor in the liver, but in the latter organ he observed extensive and well-marked fatty infiltration of the hepatic cells.

As a complication of simple fractures, fat-embolism must not be confounded with those cases of venous thrombosis starting from the neighbourhood of the injury, and where death sometimes suddenly results from detachment of a portion of the clot and its lodgment in the pulmonary artery or one of its large branches. In THE LANCET of March 1st, 1879, I published particulars of two cases of this fortunately very rare complication of simple fractures of the lower extremity, where, on post-mortem examination, embolism of the pulmonary artery was found, causing sudden death.

The whole question of fatty embolism is still involved in much obscurity, and, from the importance it possesses both in its clinical and its pathological bearings, it is one well worthy of further investigation.

LITHOLAPAXY IN BOMBAY.

By H. BLANC, M.D.,

PROFESSOR OF CLINICAL SURGERY, GRANT MEDICAL COLLEGE,
BOMBAY.

I THINK that the new rapid method of lithotripsy will meet with a large field of usefulness in India. In this country the stones found in adults are frequently too large to be operated upon by the old method, and, moreover, the natives are adverse to submit to repeated operations to rid themselves of a disease which they expect us to remove at once; hence lithotripsy has never been very favourably looked upon by surgeons practising in India. The six cases of litholapaxy here given did remarkably well. I used an ordinary lithotrite, not being able to obtain the more powerful one recommended by Dr. Bigelow, and the fragments were removed by means of Sir H. Thompson's improved evacuator. In my last three cases I made a small incision to the meatus, and this enlargement of the narrowest part of the urethra greatly facilitated, I found, the introduction of the evacuating catheter.

CASE 1.—Poona Ghar, age forty, a Hindoo, was admitted into the clinical wards of the I. I. Hospital on Nov. 2nd, 1879, suffering from stone in the bladder. The disease is of three years' duration. The patient, of temperate habits, is much worn out by pain and sleepless nights. Suffers from lumbar pains. Urine of a pale-yellow colour; sp. gr. 1009, no albumen; no pus. On Nov. 11th lithotripsy was performed. The sitting lasted thirty-five minutes, and a large quantity of débris removed by the evacuator. Moderate reaction followed. On the 15th a second sitting of thirty minutes, and on the 23rd a third sitting of ninety minutes. Before removing the patient from the operation table the bladder was thoroughly examined, and no débris could be found. No reaction and very little pain followed.

On Dec. 6th the report of his case states: "Urine quite clear; micturition quite easy and natural. Discharged perfectly cured."

Weight of fragments 306 grains. Nature of calculus uric acid.

CASE 2.—Ezekiel Mordecai, a Baghdad Jew, aged thirty, was admitted into the clinical wards of the I. I. Hospital on Nov. 16th, 1879, suffering from stone in the bladder, and from internal and external piles. The disease is of ten years' duration. Suffers from lumbar pains. Micturition attended with great pain; urine deep amber colour, sp. gr. 1016; albumen present (due to blood); urine on cooling forms a considerable deposit, which, under the microscope, is found to consist of phosphates, pus, and epithelial cells. On Nov. 25th lithotripsy was performed, the sitting lasting ninety-five minutes, the amount of débris removed weighing 480 grains. Scarcely any reaction followed, but the urine for several days was tinged with blood. On Nov. 29th a second sitting of twenty-five minutes, the débris on this occasion weighed 246 grains. Mild reaction followed, and for several days he complained of pain in the perineum during micturition, and the urine, which was bloody for the first twenty-four hours following, afterwards contained some pus. Under treatment this subacute cystitis readily disappeared, and he was discharged cured on Dec. 31st.

Weight of fragments 726 grains. Nature of calculus uric acid.

CASE 3.—Burgugu Eduljo, aged twenty, a Parsee, was admitted into the surgical clinical wards of the I. I. Hospital on Dec. 4th, 1879, suffering from stone in the bladder. The disease is of two years' duration. General health fair. Urine amber colour, sp. gr. 1020. It contains a large amount of pus and mucus, and the microscope detects oxalate of lime. No lumbar pains, but suffers from frequent desire to pass water. On Dec. 7th lithotripsy was performed, and the stone entirely removed in thirty-two minutes. It was exceedingly hard to break. Moderate reaction followed, and for several days the urine was much tinged with blood. He complained of great pain during micturition, but the symptoms gradually lessened, and he was discharged cured on Dec. 31st.

Weight of stone 180 grains. Nature of calculus oxalate of lime.

CASE 4.—Mypathi Juxmow, aged thirty, a Hindoo, was admitted into the clinical surgical wards of the I. I. Hospital on the 19th March, 1880, suffering from stone in the bladder. The disease is of two years' duration. General health good; urine clear, sp. gr. 1013, no albumen present. The operation of lithotripsy was performed on the 23rd March, the sitting lasting twenty-eight minutes. Almost all the stone was removed, and no fragments would have been left had not the sitting been suspended owing to the patient's becoming violently sick, the cause being bad chloroform. On the 28th March the remaining fragments were crushed and the débris removed in a short sitting of five minutes. No general reaction followed either sitting. After the first sitting the urine was slightly tinged with blood for twenty-four hours. He was discharged cured on the 4th April.

Weight of the fragments 270 grains. Nature of calculus oxalate of lime.

CASE 5.—Jam Alladin bin Mahomed, aged twenty, a Mussulman, was admitted into the clinical wards of the I. I. Hospital on March 20th, 1880. The disease is of two years' duration. The previous history of the case is the following: Two years and a half ago he fell on his pelvis from a certain height, and a long chip of wood about half an inch in thickness penetrated into the rectum and pierced the bladder. The piece of wood was withdrawn by his friends, and for the few following days the urine constantly trickled through the rectum; but the communication between the rectum and bladder soon afterwards closed, and the urine was again expelled by the urethra, mixed with pus and blood. This condition lasted some six months, when the urine gradually cleared. His general health is indifferent; he is pale and anæmic, and he frequently suffers from attacks of malarious fever. The urine is muddy, and contains sand. At times he suffers from much pain, and shortly afterwards he passes pus and blood again for a few days. A small stone was felt with the sound free in the bladder.

On March 28th the crushing operation was performed, the patient being rendered insensible by a mixture of chloroform, ether, and alcohol, nevertheless he took the anæsthetic badly, and one ounce and a half of brandy had to be injected per rectum before the operation was begun. Scarcely had the stone been divided by the lithotrite when the blades were found to be locked. Finding it impossible to open them again, the screw was firmly tightened, and the instrument with great difficulty, but very gently, withdrawn, when a piece of wood an inch in length was found firmly lodged between the blades. The lithotrite was again introduced, and after some calcareous matter had been crushed, another piece of wood was extracted, this time without difficulty. That evening some reaction followed, and the patient complained of much burning pain in the urethra. The next day both temperature and pulse fell to normal, while the urethral pain greatly lessened. For the first twenty-four hours the urine was slightly tinged with blood.

The patient, although progressing favourably, still complained of some pain at the end of micturition. The bladder was therefore carefully examined with a lithotrite, and another small piece of wood seized and removed. Since then the patient is quite well.

Weight of fragments 120 grains; weight of wood 30 grains. Nature of calculus phosphates and uric acid.

CASE 6.—Nag Rune Ally, age thirty-five, a Hindoo, was admitted into the clinical wards of the I. I. Hospital on April 17th, 1880, suffering from stone in the bladder. Duration of disease six years. General health good. Complaints of frequency of micturition, and of pain in the pubic region when walking and at the end of micturition. Urine high-coloured; sp. gr. 1024, contains no albumen. On the 20th April the operation of lithotripsy was performed, the sitting lasting fifty-five minutes, including the time spent in removing the débris. Slight reaction followed, and the urine was slightly bloody. On the third day after the operation pulse and temperature were normal, and the urine, with the exception of a little mucus, clear and healthy; but as he still complained of some slight pain at the end of micturition, the bladder was injected with four ounces of tepid water, and carefully examined with a small lithotrite, when a last fragment was detected and crushed. He was discharged well on May 3rd.

Weight of stone 430 grains. Nature of calculus uric acid.

THE COMPOUND SPHYGMOGRAPH.

By A. T. KEYT, M.D.

THE cut below represents my improved compound sphygmograph. The mechanism consists essentially of two sphygmographs of transmission and a chronograph combined in one apparatus, and all writing on the same smoked slide, the latter being regularly propelled by clockwork.

The sphygmographs are uniform, and constructed as follows:—

The base for receiving the movements is an oblong receptacle closed below by an elastic membrane, and opening above into a transmission tube. The latter is of convenient length, usually twenty-four inches, made up of alternate sections of glass and flexible tubing, and communicating by its opposite end with the vertical branch of a T passage. The horizontal branches of the T communicate each with a small chamber. Over one chamber is secured a graduated glass tube, over the other a delicate elastic disc; the chambers and passages are filled with *pure water*; and to provide for expulsion of air from the disc-chamber, a small passage connects its upper part with the index-chamber; a stopcock opens and closes this passage. At the junction of the T is placed a 3-way stopcock, which, according to its position, directs the movements to the index-tube or the disc. From the centre of the disc a pin arises, whose point is lodged in a small hollow cone depending from the writing lever, and to which it is attached by a sliding clip. The lever is light, six inches long, and its axis is pivoted to an adjustable plate. The pin-socket is usually placed half an inch from the centre of the axis. The lever's point just lightly touches the recording surface. A reservoir with a depending ampulla and stopcock conveniently regulates the supply of liquid to the apparatus. The entire apparatus, except the bases, which are freely movable in any direction, is firmly secured to suitable supports.

The basal and disc membranes are each adjusted and maintained at a standard tension by means of a proper screw device, and the standard tension for each is determined by a definite and easily applied formula. By these means uniformity in the action of the membranes is secured.

The graduated glass tube serves as a diverticulum for the liquid displaced from the base as the latter passes down upon the organ whose movements are to be observed. At the same time the liquid column displays the movements to the eye, indicating their form, and measuring with precision their amplitude and the pressure at which they are best developed. Thus the index-tube is an interesting and indispensable part of the instrument. (It is placed erect when the instrument is in use, and turned down for convenience when it is not in use.)

The chronograph is essentially a watch provided with a mechanism for marking the divisions of time. It is a complete instrument, very convenient, and its record of seconds and fifths is entirely reliable.

Two sphygmographs are conjoined in one instrument, because the arrangement is quite convenient, and so extends the application that a simple sphygmograph in comparison with this combination appears of very small value.

This compound instrument answers all the purposes of any sphygmograph, and in addition is adapted to a great variety of physiological and clinical uses. It traces in a perfect manner the pulsations of the heart and of the different arteries, of the fontanelles, of tumours, the movements, respiration, muscular contractions, &c. By means of the index-tube it exhibits these movements to the eye; by means of the chronograph it shows their exact time relations; and by means of the double arrangement it traces two movements, as of the heart and an artery, simultaneously, showing their relations to each other, and securing all the advantages of such a record. It is used with great facility, and executes the work with which it is charged with an extreme fidelity.

Cincinnati, Ohio.

CASE OF LABOUR, WITH ALBUMINURIA.¹

By STANLEY HAYNES, M.D.

ON July 24th, 1878, at 10.30 P.M., without having had any previous knowledge of the patient, I was called to attend Mrs. P—, a gardener's wife, a primipara, aged twenty-six. A nurse had arrived just before I was sent for (about half an hour previous to my attendance), and been so alarmed by the condition of the patient that she had immediately given a glass of hot brandy and water and said a doctor must be obtained directly. On my arrival the patient looked as if she had had serious hæmorrhage, but there had not been any. The face had a deadly pallor, the nostrils were contracted, the eyelids half closed and twitching, the breath was cold and breathing slow and superficial, and there was a cold perspiration on the forehead; the pulse was barely perceptible, and slow. The patient was calm and sensible, said she felt very well, and was quite unaware of there being anything unusual. She calculated she had gone between seven and eight months. There had not been any convulsions. Labour had begun about 4 P.M. with ordinary prodromata, and pains had not become regular or frequent until about 7 or 8 o'clock, when the liquor amnii, in apparently small quantity, escaped, and the patient had continued about her household vocations until then. There was no vomiting. The patient had not complained of illness or debility. (Neighbours subsequently stated she had been very pale during her pregnancy.) On examination there was not, and had not been, any hæmorrhage; the external genitals, the thighs, legs, feet, and arms felt cold, like those of a corpse, and the ankles were

¹ Read before the Worcester Medical Society, April 28th, 1880.

cedematous. The abdomen could not be termed warm. The warmest part of the body was the thorax, and that was of low temperature. I had not taken a thermometer. The os uteri was of the size of a shilling, dilatable; the presentation was left occipital anterior, and the pains came on about every ten minutes, were slight, and appeared almost unknown to the patient. Brandy and water was repeated in frequent small doses, with one-drop doses of laudanum, and heat, applied to the feet, calves, thighs, and abdomen, producing warmth where applied, but very little improvement to the circulation or respiration. The pains gradually became more frequent, and the os slowly enlarged. At about 2 A.M., as the general state of the patient continued as described, I sent for my friend, Dr. Thelwall Pike, in consultation. On his arrival at about 3 o'clock he approved of the treatment so far, agreed it would be better to watch and wait carefully unless there should seem reasons for expediting the labour, and regarded the case with anxiety. Soon after he left the pains became stronger, the labour advanced rapidly, the patient remaining cheerful and suffering very little even during strong expulsive efforts, and a recently dead female child was born. After a short interval pains recurred, and the placenta came away with very little, and that pale, hæmorrhage. The patient expressed herself as very comfortable, and soon became warmer, and I left her doing well at about 8 A.M. She made a good and rapid recovery, and seemed surprised I had been anxious about her.

When the lochia had ceased the urine became almost solid on boiling; it did not contain any casts or crystals. There was marked leucocythæmia. Under chalybeates and potassic chlorate she speedily improved, and assumed a natural but sallow appearance, and the albuminuria steadily diminished and ceased. On Sept. 3rd (six weeks after parturition) she was so far recovered she did not wish for further attendance. I advised recourse to the treatment in the event of relapse or of pregnancy.

On March 31st, 1879, eight months after confinement, I was asked to see her again, and found leucocythæmia and albuminuria, and prescribed iron and potash as before. She took this for a month only and recovered. In August she had a living child at full time, after a natural labour, and without the attendance of a medical man. Since then she has continued well.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL.

TWO CASES OF ANTISEPTIC SURGERY.

(Under the care of Mr. HAYNES WALTON.)

FOR the following notes we are indebted to Mr. Augustus J. Pepper, F.R.C.S.

CASE 1. *Strangulated Umbilical Hernia; Opening of the Sac; Recovery.*—T. D—, aged sixty-two, who had been a heavy drinker for the greater part of his life, having "taken to gin" when he was thirteen years of age, was admitted on Jan. 17th, 1880. Fifteen years before, a very small navel rupture was discovered, which gradually increased in size. On more than one occasion incarceration occurred, and the gut could only be returned by taxis under chloroform. The last time this happened was a week before final strangulation. At the time of the operation, the hernia, which was as large as a billiard-ball, had been strangulated for four hours and a half; it was very tense, partly resonant and partly dull on percussion. Vomiting had been frequent. Taxis having failed, it was decided to place the patient under chloroform; this was done, but reduction by manipulation could not be effected. Under the strictest antiseptic precautions, Mr. Walton then proceeded to divide the constriction, which was found to be situated in the neck of the sac. The hernial sheath contained about two ounces of

blood-stained serum, and a coil of small intestine, of a deep-red colour from congestion. Three sutures were used to close the wound, but no artificial drainage was employed.

On only one occasion did any elevation of temperature occur—namely, on the third day after the operation, when it rose to 102° F., but quickly subsided on removal of the sutures. The discharge from the wound was quite aseptic throughout the six days the gauze dressings were applied. At the end of this time only a superficial sore remained, and this got well with simple detergent lotions. The aperture leading from the hernial sac into the abdomen seemed to be obliterated by the time the patient was convalescent.

It may be stated that there was also a large double inguinal hernia.

CASE 2. *Blade of penknife in knee-joint; removal; recovery.*—C. H—, aged twelve years, on Dec. 29th, 1879, ran a penknife which he had carried open in his pocket into his thigh just above the knee, but the nature of the injury was only suspected the following day, when it was found that the blade of the knife had been broken off close to the hinge. The wound healed by first intention, but considerable pain and swelling in the knee-joint ensued, and on the eighth day after the accident Mr. Walton saw the case, and detected a foreign body projecting beneath the skin immediately above the left patella.

On Jan. 8th an incision was made under the spray, and the blade was removed. Some little difficulty was experienced as the blade of the knife was wedged beneath the patella, necessitating a free incision into the quadriceps extensor muscle.

The wound healed rapidly without suppuration. For a few days slight exudation into the joint could be detected, but the temperature remained normal throughout, with the exception of a rise of two degrees on one day coincidental with an attack of urticaria (not confined to the limb). The operative incision was closed by a single suture; no drainage-tube was used.

The antiseptic dressings were discontinued on the 20th, and on the 23rd the joint was encased in a plaster-of-Paris bandage. No pain or inconvenience was experienced when the lad was allowed to walk about on the 27th.

The blade of the knife was an inch and a half long.

MANCHESTER ROYAL INFIRMARY.

CASE OF LOCOMOTOR ATAXY WITH ARTHROPATHIES.

(Under the care of Dr. DRESCHFELD).

B. W—, aged fifty, mechanic, married, with no history of either syphilis or alcoholism, had always enjoyed good health till fifteen years ago, when the first symptoms of locomotor ataxy came on. These symptoms consisted in the inability to walk in the dark, and in the presence of lightning-like pains in the legs, in consequence of which he was soon obliged to give up his work. Seven years ago the pains in the right thigh, without losing their lightning-like character, became suddenly much more persistent, and obliged the patient to take to his bed, and to remain in bed for a month, when they left him as suddenly as they came. On trying to get up he found now that his right leg was much shorter than the left, and that there was a projection on the right hip, which occasionally would suddenly disappear with a peculiar noise. Any movement of the thigh or leg would, however, make this projection very soon reappear. Three years ago the left knee began to give way without any exacerbation of pain, or any sudden swelling of the joint, and very gradually assumed its present position, that of extreme backward dislocation. In consequence of these joint affections, walking, which was already difficult before, became only possible with the help of two sticks. The general health of the patient had remained very good throughout, his eyesight had been bad for some years, but he had never suffered from vomiting or any bladder troubles.

On admission patient looked well and healthy; the thighs were considerably wasted, but the rest of the body was not emaciated. The chest and abdominal organs were perfectly healthy. There was no affection of any of the cerebral nerves, except marked white atrophy of both of the discs. The pupils were contracted and reacted to accommodation, but not to light. The upper extremities were perfectly normal. The lower extremities showed the chief symptoms, and here, as regards (1) sensation, there were diminution of

tactile sensibility, analgesia of certain spots, and retardation of sensibility. The sense for temperature and weight was normal; the muscular sense was considerably affected. The patellar tendon reflex was quite absent. Both lower extremities were often the seat of the lightning pains. As regards (2) trophic changes, (a) the muscles of both thighs were flabby and atrophied, but especially the muscles of the left thigh. (b). There was marked dislocation backwards of the left thigh, so that when the patient stood the upper surface of the tibia could distinctly be felt under the skin. There was no atrophy of either of the articulating surfaces, nor any new deposit of bone round the joint, as far as could be made out on manual examination. The head of the right femur was dislocated on to the dorsum of the ilium, and could be felt as a distinct round projection; it was freely movable and could easily be reduced, but very soon slipped out again from the acetabulum on to the dorsum. Owing to this dislocation the left knee was situated four inches lower than the right knee, which difference disappeared as soon as the reduction of the head of the femur was effected. The head of the dislocated femur did not seem to be atrophied, nor were there any bone deposits to be felt about the joint cavity. A mass of bone, however, of more than one inch in length was felt, situated in the sheath of the sartorius muscle, totally unconnected with the joint, but moving freely with the muscles during this contraction. As regards (3) motility, there was considerable diminution of motor power in both legs, but more in the right than in the left; the patient was, however, able to stand and to walk with the help of two sticks; his walk was characteristically ataxic; he was unable to walk with his eyes shut, and with his eyes open his gait was very unsteady, owing to the ataxy and the dislocations.

Remarks.—Though the joint affections in nervous disorder, but especially in locomotor ataxy, are now sufficiently well recognised, yet not many cases of this nature have been recorded in English medical literature, and it is only very recently that Dr. Buzzard has again drawn attention to this subject and brought forward an interesting series of cases (*Medical Times and Gazette* Feb. 14th, 1880). The chief points of interest which are attached to this case are briefly these: 1. The presence of a mass of bone situated in the course of a muscle. Such a condition is noticed in two of Dr. Buzzard's cases, but is not usually found in the arthropathies of ataxic persons (see Talamon, *Revue Mensuelle*, 1878). 2. The gradual development of the dislocation of the knee, whilst in almost all cases reported the joint affections follow an acute effusion into the joint. 3. The absence of any atrophic condition of the articulating surfaces of the bones concerned in the dislocation, at least as far as a careful surface examination could show. 4. The absence of the "crises gastriques" which usually accompany the arthropathies.

WEST NORFOLK AND LYNN HOSPITAL.

COLLOID CANCER OF MAMMA.

(Under the care of Mr. WILSON.)

FOR the notes of this case we are indebted to Dr. Blomfield, house-surgeon.

Mary Ann B—, aged forty-two, married, was admitted on March 16th, 1880, with a tumour in the breast. Her previous history was good; her mother was said to have cancer. The patient gave the following history of the mammary swelling:—About sixteen months before she first began to have pain in the right side of the neck; this was followed by pain in the right breast. She first noticed the swelling in the right breast as a small lump the size of a nut. It increased gradually, and with little pain. She thought she had lost flesh. She was, however, a healthy-looking woman. Examination of the right breast showed a hard, circular, somewhat nodulated, and fairly movable tumour, the size of a chicken's egg. There was no retraction of the nipple. The tumour occupied the posterior part of the right breast to the axillary side of the nipple. There was a suspicion of slight enlargement of a gland in the axilla.

The growth being regarded as malignant, Mr. Wilson removed the entire breasts by the usual operation. The naked eye appearance of the tumour after removal was characteristic. It consisted of a somewhat circular mass of jelly-like semi-transparent material of a greyish hue, surrounded by no very evident capsule, with delicate shreds of connective tissue between jelly-like masses.

Dr. Creighton, of Cambridge, kindly examined the tumour, and reported: "The sections show the most typical colloid condition, roundish spherical masses concentrically laminated; the whole field is made up of such round laminated bodies, and there is hardly a trace of any cellular formation."

The wound did well, healing rapidly, and the slight glandular enlargement in the axilla disappeared.

The patient was discharged cured on May 8th, 1880.

STAMFORD AND RUTLAND INFIRMARY.

LITHOTRITY, WITH RAPID EVACUATION (BIGELOW'S METHOD); TWO SITTINGS; CURE.

(Under the care of DR. NEWMAN.)

IN the early days of any novel procedure it is always well to bring under the notice of the profession cases which may yet throw some light on the value of the special treatment in question.

W. W.—, aged sixty-five, labourer in a maltkiln, was admitted April 20th, 1880. Since August, 1879, he had had every indication of stone in the bladder; blood had passed with the urine, thick matter was at times present, and he had very frequent calls to pass water with even considerable pain. If he sat very still in his chair for some time the pain was not so severe, and the need for micturition became less urgent.

On admission he was a stout, flabby-looking man, and declared that he had very good general health, as a rule, but had of late lost nearly a stone in weight from broken rest and continual pain. The urine showed sp. gr. 1025, normal acidity, cloud of mucus, no blood, no albumen, no sugar; crystalline deposit of uric acid in moderate quantity.

On April 21st Dr. Newman sounded him, and readily struck a calculus, lying rather to the right side. The next day, wishing to measure the calculus, it was caught, and measured with Thompson's scoop lithotrite. It was half-an-inch across; but when an attempt was made to shake the stone from the grip it was found that the blades had taken too firm hold of a soft stone, and the stone had therefore to be crushed before the instrument could be withdrawn. Nine grains of debris were removed in the jaws.

On April 24th ether was given, and profound anaesthesia kept up for twenty minutes. The bladder was partially filled with water, and three introductions of a screw fenestrated lithotrite for the first time, and three of the ordinary scoop lithotrite for twice more, were practised. After each crushing Bigelow's elastic exhauster, attached to a No. 16 slightly-beaked catheter, was employed.

Twenty grains of fragments were removed. The instruments were actually in the bladder for nine minutes and three-quarters. There was frequent micturition and some urethral smarting after the operation. Twenty-four hours after the sitting he was hot and cold for three hours, and temperature (normal before) was found to be 101°. This feverish attack soon, however, passed by, and his local suffering became much less. Thirteen grains of fragments were passed within the next few days.

A week after first dealing with the case, on May 1st, the same crushing and removal of fragments were put in practice. The man was under ether for forty-five minutes, and little over thirty minutes was given to the actual operation. Eighty-three grains of stone removed at the time. Twenty-one grains were subsequently passed with urine—in other words, one hundred and fifty-six grains of lithic acid were collected within twelve days. (A single fragment, weighing twenty-one grains, was removed at the time of second operation through the evacuating catheter.)

The man had no subsequent feverishness and no trouble. The urine was noted to be perfectly clear on the fourth day after the second sitting. No remaining fragment could be detected by very careful sounding, and on May 11th, seventeen days after the commencement of the surgical treatment, the patient went home quite well.

Remarks by Dr. NEWMAN.—Few words of comment are needed. The stone was thought probably to be not very large, and lithotry, on the older lines of working, would most likely have ended in perfect cure, but with much more of time, suffering, and greater risk. The operation proved to be more tedious than difficult, and there was no hitch in the working of the elastic evacuating bulb. I would only add that when, as in this case, there is prostatic enlarge-

ment, it seems very desirable to keep the catheter well home within the cavity of the bladder.

Medical Societies.

EPIDEMIOLOGICAL SOCIETY.

A SPECIAL meeting of the Society was held—President, Sir Joseph Fayrer—on June 15th, to discuss certain papers which had been read during the past session on the “Continued Fevers of India and Tropical Climates.” Three of these papers, one by Deputy-Surgeon Dr. J. Ewart, one by Surgeon-General Dr. C. A. Gordon, C.B., and one by Dr. W. G. Don, were printed and circulated amongst the members, together with others known to be interested in the subject, and they dealt specially with the questions whether the common continued fever of those countries was enteric fever, and if so, whether it was due, as in this country, to a specific poison associated with conditions of excremental filth.

After a few preliminary remarks by the President, the debate was opened by Surgeon-General MURRAY, who expressed an opinion that continued fever in tropical countries differed materially in its signs and type according as those attacked were natives or Europeans.—Sir WILLIAM SMART, K.C.B., referred to the marked mildness of the various forms of continued fever in the islands of Bermuda, and he gave the result of his experience in China, where, he alleged, enteric fever was recognised as a distinct disease in 1859; but as no history of its incidence upon the natives prior to that date could be ascertained, it was inferred that it had been generated amongst the British forces who at that time were exposed to local conditions of excremental poisoning.—Inspector-General LAWSON held, as the result of experience at Mediterranean stations and in Cape Colony, that simple climatorial causes did not lead to enteric fever, unless, indeed, as a predisposing cause in special localities where faecal causes also obtained.—Surgeon-Major WHITE referred especially to Assam, where fever of the enteric type had prevailed until conditions, which up to that date had led to the excremental fouling of water, were abolished, and then the disease subsided.—Dr. BUCHANAN could only profess to look at the subject of Indian fevers by the light of experience gained in the study of continued fevers in England. Referring to the papers specially under discussion, he pointed out that attempts seemed to be made to identify a disease now by means of some anatomical character, now by means of clinical symptoms, or thirdly, by an appeal to considerations of cause. The last means of identifying disease appeared to him questionable. In England we were content to know enteric fever by the total of its symptoms and pathological appearances, and to proceed from that standpoint to the investigation of cause. We had long known the clinical disease, and had not yet become fully acquainted with the circumstances of its production. Given a continued fever with more or less diarrhoea and spleen enlargement, with special characters of temperature curves, with successive crops of rose spots on the skin and with certain anatomical characters in the fatal cases, we have known it as enteric fever. In England, having come to know our disease, and not till then, we have gone on to learn lessons about its association with one and another external condition, and then by degrees we were learning of its causation. But the numerous and valuable results that inquiries about causation had heretofore yielded did not prevent our having, but rather led us to have, ever fresh doubts whether we know all the conditions for the appearance of the disease, and assuredly had taught us that we did not yet know the conditions for its production. Inquiry as to the way in which fever had made its appearance in a household—to say nothing of inquiry, in a stricter sense, as to “cause”—had been found to involve a process of living over again, as it were, the life of each patient before his attack, with differentiation of his life from that of other people. That process was difficult enough of accomplishment under the conditions of English society, but must needs be incomparably more difficult where a fever occurred in indi-

viduals of an alien race having traditions and caste-notions separating them by wide intervals from the people who were endeavouring to investigate the origin and spread of disease among them. The impression that Dr. Buchanan had received from a study of the three papers was that it was perfectly permissible to regard much of the described fever of India as being identical with European “enteric fever.” It was modified, no doubt, by circumstances of Indian life, yet did not appear to differ more from our own enteric fever than one case or one outbreak might differ from another case or another outbreak of this multiform disease when it was witnessed in Europe. It was not from any single one of these three papers that he had formed this opinion, but it was essentially from observation of what the three papers, taken together, appeared to him to agree upon.

Mr. NETTEN RADCLIFFE dealt in detail with many points specially referred to by Surgeon-General Gordon, who, though admitting that, so far as symptoms and pathology were concerned, a disease resembling enteric fever did prevail in India, yet denied that it was etiologically the same, and even threw doubts as to the views held regarding the etiology of the disease in England. Mr. Radcliffe pointed out that Dr. Gordon had implied that the continued fevers of India were but one single form of fever, whereas in his paper he at once proceeded to divide them into as many as twelve groups. Dr. Gordon had further quoted in support of his views as to the unity of “fever” an opinion of a distinguished author, which was penned as far back as 1843, since which date that author had, as was well known, not only changed his views, but had accepted the classification of the continued fevers enumerated by Stewart and Jenner. Dr. Gordon’s use of the term causation was most misleading, points being referred to as causes which in reality were nothing more than conditions, associated with the prevalence of disease. The study of climatology in connexion with disease was of the utmost importance, but the assertion that an infectious fever was of climatic origin, when even the local circumstances under which it existed were not recorded, was damaging to the cause of epidemiology; for, although it was obvious that climate governs every condition of life, health, disease, and death, yet that did not necessarily constitute it a cause of any special disease. Dr. Gordon’s materials were also misleading, and having been obtained as the result of the issue of circulars to a large body of medical officers spread over a vast area, they were almost necessarily untrustworthy. Anyone having experience of the difficulties associated even in this country in investigating causes of epidemics must know how little value is to be attached to data got together in such a manner. But even accepting the facts recorded in the returns issued, they, in some important respects, led to conclusions diametrically opposed to those embodied in Dr. Gordon’s paper. As to the 175 cases on which Dr. Gordon chiefly based his conclusions, that gentleman had submitted that *seven* only were real cases of enteric fever, the others being, as he argued, so-called “climatorial” fever. Of what value it was asked could seven cases, scattered over several years, and distributed in a wide territory, be in determining a question of this kind. But Mr. Radcliffe proposed to accept the diagnosis as given by the recorders, and was not prepared to admit a greater margin of error in diagnosis than would have occurred if a similar number of medical practitioners had been applied to by circular in England. What followed? Why, 25 per cent. of the total cases furnished no evidence whatever either in one way or another with reference to the question of etiology, and, deducting these cases, it was found that the greater proportion of the remainder (53·5 per cent.), according to the recorders, had occurred under conditions of “faecal effluvium from latrines,” or the patients had been exposed to chances of infection or to local conditions which are known to be chiefly associated with enteric fever. He was quite unable to reconcile these data with Dr. Gordon’s statement, that in not a single one of these cases was there any evidence of the existence of such “causes” of enteric fever as govern the prevalence of that disease in Europe.

Dr. W. DICKSON considered that in tropical climates the continued fevers were attended by many more complications than in Europe, and to this was due many of the differences of opinion which were held with regard to them.—The PRESIDENT, quoting from official statistics, drew attention to the fact that enteric fever was recognised as the principal fatal fever in many parts of India; but at the same time he expressed a conviction that there is a form of “fever” in tropical climates which, as regards its cause, is not identical with

the enteric form of this country.—Dr. GORDON, who quoted largely from official and other reports, with reference to the comments which had been made, explained the circumstances under which the inquiry on which his report was founded had been directed, and stated that he had necessarily been kept within the lines laid down by the Army Sanitary Commission. He maintained the opinion that in hot climates a fever resembling enteric fever in its symptoms prevailed, but that it was due to climatic influences and not to filth or other specific causes; he further stated that ulceration of Peyer's patches took place in connexion with a form of fever which was alone due to climatorial causes.—Dr. W. G. DON maintained similar views, asserting that local insanitary conditions occupied, in the production of continued fever, a less important influence than that of climate, and that enteric fever would still prevail in tropical climates if all those conditions were removed.—Dr. EWART, however, argued from his experience that enteric fever as it prevailed in India was not due to climate; he denied that so-called malaria had any influence in producing it, and as the result of lengthened experience he stated that he had never met with that disease except where it was dependent on the same causes as those with which its prevalence in England was associated.—Dr. A. P. STEWART was specially called upon to address the meeting. He had, however, at a previous meeting declared himself entirely opposed to the doctrine enunciated by Dr. Gordon, and had expressed the opinion that views such as those held by Dr. Gordon and Dr. Don reminded him of the state of medical opinion in this country some twenty-five years ago, before the pathology of enteric fever, as well as the difference existing between that disease and the other continued fevers, were understood, and he felt that after perusing the papers he had nothing to add to the statement he had then made.

CAMBRIDGE MEDICAL SOCIETY.

Menorrhagia in old age through emotional disturbance.—Diabetes from same cause.—Therapeutic uses of Hyoscyamine.—Secondary Pelvic Tumour.—Gummata in Brain, Liver, and Testicles.—Bovine Tuberculosis in Man.

At a meeting of the Society on the 4th June, Professor Paget, M.D., F.R.S., President, in the chair,—

The PRESIDENT related two cases in which a discharge of blood from the womb, which the patients spoke of as the menstrual discharge, had been brought on in advanced years through emotional disturbance. The influence of emotion is not often manifested in causing menorrhagia when years have elapsed since menstruation had naturally ceased. In the first case, a married woman aged sixty-five, a sanguineous uterine discharge had been continuing for three weeks before she presented herself; it had been brought on, she said, by the return of her son from abroad. In the absence of any other assignable cause, there could be no doubt that this emotion attending her son's return was really the exciting cause. He was her only surviving child, he was in prosperous circumstances, and his return had been eagerly expected. Fifteen years had elapsed since her last menstruation. The discharge soon ceased under treatment with iron.—The second patient, aged sixty, lost her husband, and soon after her daughter, who died suddenly in childhood. Her mental distress was very great; her mind became disordered; simultaneously menorrhagia came on, and she had also a delusion that there was a baby in the bed. The catamenia had ceased naturally many years before.—As regards the first case, some explanation of the unusual occurrence may be found in the previous history of the patient. Though she had been quite well for years before her son's return, she had formerly been epileptic, and had had an epileptic son. This nervous constitution was probably a predisposing cause. The history of her epilepsy gives us further hints of concurrent causes. The fits began when she was forty-five years old, when her menstruation was beginning to be less regular than it had been. For two years previously she had been subject to attacks of faintness with vertigo. These syncopal or minor

epileptic attacks had come on after the death of her epileptic son in London after a few days' illness with enteric fever. The fits were very severe, and kept recurring for some years. In one of them, in which she fell backwards, striking her head violently against the floor, there was, simultaneously with the fit, a slight "show" of the catamenia, which had previously not appeared for three years. Before the fit she had a painful uneasiness in the right iliac region, and a kind of aura proceeding from this point, and occasioning a feeling of alarm. The same phenomena followed another epileptic fit two years later. The circumstances under which she became epileptic (the death of her son) indicated maternal feelings unusually strong. The time at which she became epileptic (when the catamenia were beginning to be less regular) indicated some connexion between the functions of the organs of generation and the state of nervous system which manifested itself in epilepsy. The like is indicated more definitely by the slight menstrual discharge accompanying one of her fits, and the abnormal sensations in the region of the right ovary on this and another occasion, so that we are not wholly at a loss to account for the unusual occurrence of menstrual flow being excited by emotion in this woman at the age of sixty-five.

The PRESIDENT related also in connexion with the above cases two cases of a disease that much more commonly follows emotional disturbance—viz., diabetes. In the one case the patient was a woman, aged forty-four, the wife of a farmer; the diabetes came on while she was, and had been for some weeks, anxiously nursing her only son in a dangerous illness. The quantity of urine was large, the sp. gr. 1039, and contained a large quantity of sugar. In the other case the patient was a woman whose husband died in good circumstances, leaving her his executrix. Grief for the loss of her husband, combined with the worry of managing his affairs, brought on diabetes, of which she died six months after her husband.

Dr. BACON gave an account of the preparation known as "Hyoscyamine," and of its therapeutic uses. There are two preparations sold under that name, both made in Germany. One is Merk's "Extract of Hyoscyamine," and the other is a crystallised preparation in the form of a whitish powder and of variable strength. His experience has been limited to Merk's extract. It is most conveniently administered dissolved in alcohol, one grain to the drachm. The solution mixes badly with water, a resin forming on the sides of the bottle. The preparation deteriorates by keeping; if it become greenish in colour, it is a sign that its strength is lessened and that its action may not be relied on. It is called by the manufacturer the "extractive amorphous alkaloid" of hyoscyamus, and is very costly. With this preparation he has found the effects much more potent, and more certain and reliable than those of ordinary henbane. Its action is that of a powerful sedative and hypnotic, and it is the only sedative and hypnotic in his experience whose action may be certainly relied on. Doses as large as two or three grains (of Merk's extract) have been administered; he had himself never given more than a grain and a quarter, and his usual prescription was three-quarters or one-half a grain. If three-quarters of a grain be given to a maniacal patient in a state of excitement, he will be reduced in half an hour to absolute helplessness, and will be probably asleep or comatose. The lips become red, the face dusky, and the saliva flows from the mouth; the pulse is quickened and there is dilatation of the pupil, lasting for twenty-four hours; the other symptoms pass off in about twelve hours. Vomiting had occurred in two or three of his cases. The drug is especially valuable in treating the maniacal condition (chronic or acute). It had been used in delirium tremens, and its power of inducing quietude and sleep to a certainty indicated its value in that condition. In some cases the beneficial results flowing indirectly from its use had been so great that he had been able, after a time, to disperse with the drug. Two cases had occurred in his practice which would serve to show where caution was necessary. In the one (a private patient) only half the dose prescribed was given, and the patient, instead of being sent to sleep, was put into a state of excitement and delirium. In the other an accident, fortunately not fatal, followed the administration of the drug. The patient had become profoundly insensible, and had vomited, and part of the vomit (consisting mostly of partly digested bread) appeared to have got into the air-passages, giving rise to corresponding symptoms.—Dr. LATHAM could not join in Dr. Bacon's opinion that henbane in its usual pharmacopoeial form is quite un-

reliable. The potency of the leaves no doubt depended on the time of gathering them, and on the care with which they were dried.—The PRESIDENT referred to the experience of a neighbouring practitioner, who had the henbane grown near him, and the extract made by a trustworthy person, and who always found the drug so obtained to be potent and reliable in its action. He had the other day prescribed henbane in a bad case of epilepsy, which no other drug had benefited, and the result was that the patient had been altogether free from fits for three weeks, and when they recurred they were less frequent than before.

Dr. EASBY showed a large tumour weighing upwards of four pounds, which seemed to have grown from the left ilium, in a woman fifty-two, who had the left breast amputated for cancer two years before.

Dr. BRADBURY gave an account of a case in which gummata were found after death in the brain, liver, and testicles. The patient was a man aged thirty. The first symptoms, eight months before admission, were pain in left arm and shoulder, and loss of power in left arm and hand. Under treatment the symptoms disappeared in a fortnight. Three months after he had pain in the supra- and infra-orbital regions of the right side, and gradually lost sensation over the whole of the right side of the face, the pain meanwhile increasing in severity. A month before he came in, he suddenly began to squint with the right eye, and experienced "flashings" before the eyes, which came on sometimes two or three times a day. About the same time both testicles began to swell, without pain, and continued to increase in size. He observed also loss of taste on the right side of the tongue. On admission, he had most of the above symptoms. The squinting referred to was marked internal strabismus; there was also a degree of ptosis. The tongue deviated a little to the left, and the levator muscles of the angle of the mouth on the right side were in an almost tonic condition of spasm. A few days after admission the conjunctival vessels of the right eye were congested (January 28th), and on February 9th there was a small spot of commencing ulceration on the cornea. The ulceration on the cornea continued to spread for some days, and then began to heal. On March 9th the ulcer was healed, a patch of opacity remaining. Congestion of the conjunctival vessels reappeared after a time; and a few days before his death (on May 24th) the opaque area of the cornea sloughed. Meanwhile the pain in the face, and the spasm of facial muscles, varied in degree from day to day, and there was some left facial paralysis. He began to pass the evacuations in bed, and there ensued marked loss of strength, general tremors of the body, constant twitching of the lower lip, speech almost unintelligible. Before death the left hand was completely paralysed. He was treated with calomel and iodide of potassium. Post-mortem: The tunica vaginalis on both sides was distended with fluid; body of testes considerably enlarged; on section two large nodules of yellowish-brown substance (gummatous) in each testis, and an appearance of parallel whitish streaks (interstitial orchitis). The liver showed extensive depressions and puckering of both surfaces, the acini greatly enlarged in certain places, and gummatous nodules (up to the size of a bean) chiefly in the thin left lobe. Within the cranium, attached to the dura mater and making a depression in the surface of the brain about the centre of the right ascending parietal convolution, was a firm round and flat gummatous body, about the size of a horse-bean. On the surface of the pons Varolii on the right side, involving the roots of the fifth and sixth nerves, and just overlapping the origin of the seventh, was another flattened gummatous mass. Another gumma was found on the upper surface of the cerebellum, in the middle line anteriorly, situated in the membranes, and not involving the substance. On section of the brain, a large mass of semi-transparent gelatinous substance, with an opaque yellow centre, about the size of a walnut, was found in the occipital lobe of the left hemisphere near the surface. The right corpus striatum and optic thalamus were softened, and broke down readily under a stream of water.

Dr. CREIGHTON gave an account of observations, microscopic and other, on eight cases of a peculiar variety of tuberculosis which he believed to be Bovine Tuberculosis communicated to man. (See THE LANCET, June 19th, 1880.)

At a Convocation held at the University of Durham on the 22nd June, Dr. Pyle of Sunderland was elected a member of Senate of the University.

Reviews and Notices of Books.

Army Medical Department Report for the Year 1878.
Vol. XX. Parliamentary Blue-book, pp. 332.

[SECOND NOTICE.]

WE have so recently noticed the health of the Army in India in 1878, in our review of the Report of the Sanitary Commissioner,¹ that it seems unnecessary to enter again upon the details. We would merely refer to an interesting table furnished by the Principal Medical Officer in Bombay, showing the comparative mortality and invaliding of officers, non-commissioned officers, and privates in each of the ten years from 1869 to 1878 inclusive. The average of the whole period is as follows:—

Per 1000 of mean strength.	Officers.	Non-com.	Officers.	Privates.
Deaths	11.35	21.12	14.05	
Invalids	90.35	41.66	40.18	

The most striking features in this comparison are, the high rate of mortality of the non-commissioned officers as compared with the privates, and the proportion invalided of the officers compared with both. It may be a question how much the lower rate of mortality of the officers depends upon this circumstance. Not only was the invaliding of soldiers from India in 1878 above the average, as shown in the Report previously noticed, but the number discharged at Netley was one-third higher than in the preceding ten years. There was a very large increase in the number discharged under the head of "debility," probably the result of malarious diseases.

The extracts from the sanitary reports of stations at home and abroad afford good evidence of the watchful care exercised by the medical officers. They also show the steady, though, we regret to add, too slow progress of improvement in the sanitary conditions of the quarters occupied by the troops. They are, however, of such a nature as to preclude our making any summary of them, and we must content ourselves with referring our readers to the Report itself. We may, nevertheless, notice two circumstances. The first is the appearance at Mauritius in the end of the year of a new disease in the district of Moka, and which subsequently spread to other localities. It has since been diagnosed as "beri-beri." It has been confined entirely to the Indian population, and chiefly to those whose caste prohibits the use of meat. It is stated to have been found amenable to treatment, particularly in cases which came early under observation. The other point we would note is that at Hong-Kong, during the period of rifle practice, as malarious fevers were very prevalent at Kowloon, the men, instead of being quartered there, were taken over and brought back daily in steam launches, and with the most satisfactory results.

The appendix to the volume begins with the report on the progress of hygiene, by Professor De Chaumont, under the usual headings of Legislation; Work of Societies, &c.; Literature; and Special Points of Hygiene. Under the last is given a tabular statement of the results of 68 analyses of drinking water sent to Netley from various stations of troops at home and abroad. Of the 68 waters reported upon, 27 were fit for use, 22 usable or required filtration, and 19 unfit. These results would have been more valuable had the combustion method been employed and the nitrates determined. As it is, we are inclined to doubt the correctness of the judgments pronounced upon some of the waters. The experiments on filtration previously recorded have been continued. A new filtering agent, called "carferral" (carbon, ferrum, alumina), has been tried, with great success so far. It is even placed before spongy iron, which, however, is shown to be very valuable. Further experiments

¹ THE LANCET, May 29th, p. 854.

are, however, necessary, as the lasting power of the filter cannot be said to have been ascertained.

Another interesting but, we think, equally incomplete research upon Disinfectants is contributed by Surgeon-Major J. Lane Notter. The valuation of disinfectants is confessedly a most difficult matter, and the results hitherto obtained are singularly contradictory. The method adopted in the present experiments was simple enough. Beef infusion, swarming with bacteria, was treated with five, ten, and fifteen cubic centimetres of 10 per cent. solutions of fifteen different disinfectants, and the liquid examined with the microscope, immediately or after twenty-four hours. Under these conditions chloride of lime was found most efficacious, and the green terebene powder next. Tests of this kind have, however, only a limited value, as there is no proof that the real, or at any rate the only, work of a disinfectant is to kill bacteria. There are moreover certain apparent discrepancies in the results which puzzle us. Thus Burnett's fluid (chloride of zinc) takes a very respectable place, as it has done in so many previous experiments; whereas the new disinfectant, sporoktin, is represented as worthless. Now, sporoktin is merely an alcoholic solution of chloride of zinc saturated with sulphurous acid; and we fail to see how the presence of sulphurous acid can destroy the efficacy of chloride of zinc. It is curious that sulphurous acid should not have been included in the experiments. Whether it will kill bacteria or not, it will be difficult to convince medical men who know the history of the cattle-plague epidemic that it is useless as a disinfectant.

Dr. De Chaumont gives a very brief notice of an epidemic of enteric fever in the Royal Marine Artillery at Eastney Barracks, Southsea, upon which he and Professor Macdonald, R.N., were called to report. Here is his description of the condition of the barracks:—"We found that the drains were unventilated, that the overflow, waste, and sink pipes passed direct to the drains, and that the closets were untrapped except by means of the antiquated D trap. The sewage passed into the sea, but the tide washed up the sewer at high tide to some distance, blocking back the sewage and favouring the production of sewer gases. The blocks of building most affected were the officers' quarters, or those which would be most directly or immediately affected by this action of the sea water." And this state of things, be it observed, in a barrack first occupied in 1864! Who was responsible for this malconstruction, and how did it happen that Sir A. Armstrong never discovered it, for as a marine barrack it must have been under his department?

In accordance with the custom of preceding years, the late lamented Surgeon-Major Porter drew up his tabular summary of the capital operations performed at Netley during the year 1878, the last in which he held the appointment of Assistant Professor of Surgery. Notes and lithographic illustrations are given of some of the more interesting cases, and the results of treatment in thirty-seven cases of permanent stricture of the urethra, all of them invaded from foreign stations.

We again note with regret the absence of any communication from the professors of Medicine and Pathology. It surely is not too much to expect that they should turn to good account for the profession generally, as well as for the Army Medical Department, the splendid field of observation they occupy at Netley.

South Africa has furnished the subjects for four papers in the appendix. The first is a very interesting medical history of the Galeaka-Gaika War in 1877-8—that with the Kaffirs which preceded the Zulu War—by Surgeon-General Woolfreyes, the principal medical officer at the Cape; the second is a tabular statement, by Surgeon-Major Hickson, of the wounds and injuries received in action during that war; the third, a short, but spirited account of the defence

of Rorke's Drift, by Surgeon-Major Reynolds; and the fourth, a very brief report on the climate and diseases of Natal and Zululand, by Surgeon-Major N. Alcock. The details connected with the health of the troops in the Zulu War will, of course, be given in the next volume. There are two other papers which we shall just mention—"Remarks on Enteric Fever in India," by Surgeon-General Ker Innes, C.B.; and "Cholera, its Natural Laws and Progress," by Surgeon-Major Marston. We noticed these papers so very fully when they first reached this country that it is unnecessary to revert to them.² As we have in the course of these remarks pointed out some of the deficiencies which have struck us in the report, we shall only in conclusion express our regret at the continued absence of the abstracts of diseases, &c., in the different military commands, which in the earlier volumes furnished so much valuable information, and enabled us to check the statements made and opinions given in the reports. It is due to the Medical Department to say that the blame of the shortcoming does not rest with it, but is a result of the miserable ignorance or petty economy of the authorities at Her Majesty's Stationery Office, and at the Treasury.

The following interesting table shows at a glance the sanitary condition of the British Army during the year 1878:—

Atlas of Histology. By E. KLEIN and E. NOBLE SMITH. Part XI. Smith, Elder, & Co. 1880.

THIS part contains the Urinary Organs, the Male Genital Organs, and the Female Genital Organs. The structural arrangement of the urinary tubules is given with great care, no less than sixteen separate segments being distinguished between the Malpighian capsule and the mouth by which the tubule opens upon the papilla. There are in succession the capsule, its neck; the proximal convoluted tubule; the spiral tubule of Schachowa; the descending limb of Henle's loop; the loop proper; the thick part of the ascending limb; the spiral part of the ascending limb; the narrow ascending limb in the medullary ray; the irregular tubuli; the distal convoluted tube, or Schweigger's intercalated tubule; the curved collecting tubule; the straight collecting tubule of the medullary ray; the collecting tube of the boundary layer; the large collecting tube of the papillary part; and lastly, the duct. Each of these segments is separately described. Dr. Klein remarks, that with the exception of the descending limb of Henle's loop and the loop itself, a delicate membrane exists which lines the inner surface of the epithelium; that is, it lies between the epithelial cells and the lumen. Eleven figures illustrate the structure of the kidney.

In speaking of the testes the authors follow the development of the seminal cells with much detail. They describe

² See THE LANCET, October 4th, 1879, and February 7th, 1880.

the fully developed and ripe spermatozoon as consisting of a homogeneous, well-defined discoid oval head, to which succeeds the middle piece of Schweigger-Seidel, varying in length in different animals. This portion is homogeneous and rod-shaped, and attached to it is the filament or tail, thinner and much longer than the middle piece, and ending in a pointed extremity. In man the filament is continued over the middle piece as a fine, wavy, or spiral thread. There is also a sheath which covers the hind part of the head, and is continued over the middle piece. The head of the ripe spermatozoon is the modified nucleus of the spermatoblast; the filament or tail is derived from the granular body of the original cell. The middle piece of Schweigger-Seidel is an outgrowth of the nucleus of the spermatoblast—that is, of the head of the spermatozoon; and the clear tube of the developing spermatozoon embracing the hind part of the nucleus is the sheath which in the triton is observable on the middle piece of the fully-formed spermatozoon. In considering the development of the Graafian follicles (we hope the authors will excuse us for inserting the additional *a*, which is surely the correct orthography), the account given by Balfour is followed; and here, as elsewhere, the drawings are most excellent and instructive, and are, to a great extent, original.

New Inventions.

MEDICAL AND SURGICAL BED-DRESS.

MR. GOOD, of 50, Praed-street, Paddington, has submitted to us a sample of a bed-dress suggested by Mr. H. Cripps-Lawrence. The dress, which can be made of any material, is buttoned up all down the front and back, and also from the neck along each sleeve to the wrist. It is obvious that such a dress can be applied with the greatest ease to patients unable to bear the fatigue or pain of changing the ordinary dress, and it is so arranged that any part of the body can be exposed for examination or treatment without disturbing the whole dress. It will certainly be very useful in many cases of severe illness.

DR. RADCLIFFE CROCKER'S URINE-CASE.

MESSRS. MAYER & MELTZER, of Great Portland-street, have made for Dr. Radcliffe Crocker an extremely compact and useful pocket-case for examination of urine at the bedside. The case is just over six inches in length, and is easily carried in the breast pocket. At the bottom of it are

two small bottles, containing respectively methylated spirit and three of Cooper's copper pills for testing for sugar. Above these are a nest of three test-tubes, between which are the two test-papers, which keep the tubes from shaking. Inside the inner tube is a small glass tube on a foot, containing a wick and three capillary tubes of nitric acid. Spirit is poured into the little glass, one end of the wick dropped in, and a small but sufficient spirit-lamp is constructed. With this case the practitioner can easily and rapidly exa-

mine urine for sugar and albumen. The case requires to be a little stronger than that forwarded to us, or it will not stand continual use. In addition to its extreme simplicity and compactness, this case has the advantage of being cheap.

COPPER TEST-PELLETS FOR SUGAR.

To the Editor of THE LANCET.

SIR,—May I ask you to insert a few words with reference to the copper test-pellets for sugar, which, at my suggestion, have been prepared by Mr. Cooper, of 26, Oxford-street. The object of these pellets was to supply a copper test for the examination of urine of a more convenient and staple nature than the copper solution. When kept under suitable conditions they fulfil all that can be desired. I have received information from some who have procured them that they have become moist, and thereby spoil on keeping. Hitherto they have been sent out in corked bottles rendered air-tight with sealing wax. As long as the bottle has remained unopened they have been all right, but when the sealing wax has been broken the cork has allowed the penetration of moisture, which, being absorbed by the caustic potash contained in the pellet, has led to its becoming moist. All that is wanted to prevent this occurrence is that they should be kept for use in a good stoppered bottle; and Mr. Cooper, in consequence of the representation I have made to him, has liberally undertaken to supply them in future in stoppered, instead of corked bottles. Those who now have them in corked bottles should transfer them as soon as opened to a bottle provided with a well-fitting glass stopper. By this simple measure all objection is at once removed.

I am, Sir, your obedient servant,
Grosvenor-street, July 5th, 1880.

F. W. PAVY.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—As I have a patient with scirrhus cancer of the uterus who has taken almost without intermission every four hours the pills of Chian turpentine à la Professor Clay, will you allow me to state the result of the remedy in my hands.

The patient commenced to take the pills on March 29th last, when there were all the usual local signs of advanced cancer, minus a fetid discharge per vaginam. A strong hard mass extending over the whole uterine structure, but more especially infiltrating the posterior wall, and projecting thence almost through the os. Paroxysms of pain coming on so severe that large doses of morphia were necessary to relieve them. The appetite not only gone, but the stomach refused to take almost any food. The cancerous cachexia very evident, and the patient's spirits very much depressed, and floodings much and often. Now, on examination per vaginam there is still a considerable tumour to be felt, but it is comparatively very soft and yielding to the touch, and not by any means so extensive; there is little or no hæmorrhage; pain by no means so severe as formerly, and almost entirely confined to the thigh and leg of the left side. The appetite is excellent, and the cancerous colour of the skin and complexion almost gone. The patient expresses herself as feeling very much better in every way, and is in the habit of attending to household duties and taking out-door exercise as when in her wonted state of health.

The disease in this case was first discovered on Nov. 26th last, when the tumour was situated on the posterior wall of the uterus, and only then of about the size of a walnut. There has hitherto been no disturbance of the functions of rectum or bladder, except a tendency to constipation. The disease made rapid progress until the turpentine pills were taken, and since the first day of her taking them, March 29th, so far from progressing the mischief appears to have stopped.

I may add that the glands of the neck are enlarged, and have been during the last four or five months. When painful, extract of belladonna locally applied has always relieved the pain.—I am, Sir, yours, &c.,

J. E. KENYON, L.R.C.P. Lond., M.R.C.S. Eng.

Formerly House-Surgeon to the Hospital for Women,
Soho-square, London.

Bradford, Yorks, June 26th, 1880.

THE LANCET.

LONDON: SATURDAY, JULY 10, 1880.

THE Judges adhere pertinaciously to a view of the practical question of responsibility for crime which leaves much to be desired. Mr. Justice HAWKINS, in his summing up in the case of JAMES SWEETLAND, follows the lines laid down in a well-known judgment, and asserts (we quote from *The Times* of Tuesday, the 6th inst.) that, "to establish a defence on the ground of insanity, it must be clearly proved that at the time he committed the act the accused was labouring under such a deficiency of reason from disease of the mind as not to know the nature or quality of the act he was committing, or, if he did know what he was doing, that he was not aware that the act was wrong." Further on in the same report we read: "It was impossible to define what insanity was, but as far as the criminal law went, it must be that state of mind which made a person unconscious of what he was doing, and that it was a wrong act he was committing, even though he knew what that act was." Again: "It must be that insanity which prevented a man from knowing the nature of an act, or that it was wrong." Mr. Justice HAWKINS is too sound a lawyer and too wise a judge to have given expression to an opinion at variance with the principles of law as they are still understood by the Bench. There is obviously a strange lack of breadth in the legal view of insanity as a disease; but is it so narrow as to exclude all cases of delusion in which the subject acts under a supposed self-consciousness of evil influence? The man who thinks the devil or some fiend instigates or drives him to the commission of an offence may know what it is he does, and be painfully aware that it is both wrong in itself and contrary to law, but nevertheless do it, and do it insanely in such a way that common sense must excuse, and the law can scarcely condemn, him. It is needless to cite instances of this class; the books are full of them, and even *one* would suffice to upset the postulate assumed by Mr. Justice HAWKINS.

The case of SWEETLAND is, as a whole, one of considerable difficulty. Mr. MONTAGU WILLIAMS did not put the popular argument too strongly when he said that if "insanity" were to be accepted as an excuse for crime committed "in a state of carelessness and recklessness" induced by the habit of drinking, "no person's life would be safe for a moment." It is a most regrettable circumstance that this question of responsibility is left to be raised and disputed as a ground of defence. It would be incomparably better if the plea of insanity were disallowed, and the question of *responsibility* made the subject of special inquiry after the jury had given its verdict, and before the judge pronounced sentence. Irresponsibility should never be allowed to form a question before the jury or the Court *during* a trial. It is solely a question for the Crown, and might well be determined after a prisoner was delivered over to the judge, as the representative of the Sovereign, for punishment. We should then get rid of two evils at one

sweep: 1. The importation of a foreign element into the process of weighing evidence on the question of *fact*, with which alone any lay jury can be competent to deal; and, 2, the cross play of assertion and argument, which discredits truth and science, in the conflicting interests of the opposing parties. Nothing is more undesirable on grounds of public prudence than to leave questions involving great issues to an incompetent tribunal. The balancing of technical evidence cannot possibly be a task to be entrusted to any lay judge or jury. As well set a man ignorant of the law to determine between the merits of two elaborate legal arguments, as expect a layman to decide which of two medical "opinions," the one for and the other against an accused person, is that which ought to be adopted. What would any reasonable man think of the proposal that the Lord Chancellor should be a person ignorant of the law? Yet such a proposal would be precisely in accord with the practice which sets a judge and jury, both ignorant of medical-psychology, to decide between the conflicting testimony given by medical men, called by the Crown and for the accused respectively, in a case like that we are considering. Of course neither judge nor jury can know anything about the matter in dispute, and the only indication to help them is the *status* of the opposed witnesses, which must sometimes prove an untrustworthy guide.

In the case of SWEETLAND there would seem to have been some evidence of hereditary disease, and certain peculiarities in his conduct which *may* have been symptoms of insanity, but there is really nothing in the evidence to shape the judgment of an alienist. The materials for a decision on the question of responsibility are wanting. The fact that shot was deliberately purchased, apparently with a view to the commission of the crime, counts for nothing. The most pronounced lunatics often show the greatest cunning and premeditation in the perpetration of offences. Nor is it important to either side of the case that the accused showed consciousness of what he had done immediately after the crime, and observed reticence subsequently. Those who have had much experience among lunatics will not need to be reminded of the difficulty which often besets the task of making out the formal proof of their insanity. The worst and more dangerous cases are often, if not generally, the most obscure. The diagnosis of insanity is especially a matter of personal skill. Dr. MAUDSLEY took up the only tenable position when in a recent civil case he stated his opinion as an expert, and, relying on his reputation, declined to bandy words with the unskilled cross-examiner who sought to elicit his "reasons," and discover the processes by which he arrived at his conclusions. It would be well if medical witnesses generally were as wise in their bearing. For example, in the case of SWEETLAND we would rather accept Dr. BUCKNILL's opinion on the basis of his skill as a diagnostician than entertain his hypotheses as a psychologist; and that opinion is that the man was mad when he committed the crime of which he has been convicted, and that even now he has the delusion that the deceased watched him for the purpose of doing him an injury.

The only point on which we are sufficiently well informed to adventure an opinion as to this case, and that a very strong one, is that the Crown cannot in common justice proceed to execute the sentence of death without a

proper medical inquiry. Public opinion will not be satisfied with the carrying out of the sentence until the question of *responsibility* has been determined. We cannot suppose the judge or Home Secretary will be inclined to leave the matter in the present state of incertitude. It is, therefore, only necessary to urge the expediency of prompt action. Respect for the administration and for the law is weakened when there is unnecessary delay in these cases. An inquiry *must* be instituted. It is a clumsy and costly expedient, but absolutely indispensable under the circumstances. Nothing can be gained, and something may be lost, by delay. A writer on the subject of "Impulse and Responsibility" has said: "The justification of a plea of insanity must, I think, take the form of a demonstration that the impulse alleged to have been morbid exhibits the characteristics of disease, or that it occurred in the course of a paroxysm of the malady." This pretty well covers the area and marks the limits within which the search for evidence should now be prosecuted. Every day the inquiry is delayed, the diagnosis, from the medico-legal standpoint, becomes increasingly difficult, and new sources of error are incorporated with the case; for example, the mental effects of remorse, hope, and despair, with the ever-impending, though disguised, dread of steadily approaching death. It is not politic in the interests of pure justice, with which society is chiefly concerned, to delay an examination of this character until influences which may either crush or *recover* the mind have established their sway. It seems to be forgotten that a man who was mad when he committed a crime, and, therefore, ought to be absolved, may be cured by the mental effects of his trial and condemnation!

THE annual report of St. George's Hospital and of ATKINSON MORLEY'S Convalescent Hospital, gives some very interesting data concerning the use of stimulants other than beer in St. George's and other hospitals, and include a singularly suggestive report of the "previous habits" of some of the patients, in respect of stimulants, the careful work of Dr. ISAMBARD OWEN, the Medical Registrar of the hospital for 1877-8. The London hospitals have generally acted on the view that beer was a necessary part of ordinary diet. Until 1879 that was the practice at St. George's. In that year we are glad to say, with the concurrence of the medical staff, a rule was made that malt liquor was not to be furnished except by order of the medical attendant. Ever since this rule the quantity consumed has not been much diminished. It is very desirable that the members of the medical staff should fully realise the importance of this question. In other institutions the reduction of the quantity of stimulants or their entire withdrawal would seem to have done nothing but good, and it is probable that careful experiments in this direction might be the saving of many a hospital patient morally and physically.

A committee was lately formed at St. George's to ascertain the comparative use of alcohol in twelve large London hospitals. About a fourth of the patients it is found in all the hospitals are under daily treatment with stimulants other than malt liquor, which would seem to be a matter almost of course. The proportion of those receiving wine and stimulants is almost the same at St. George's. The variation in

the quantity of wine and spirit per patient in the different hospitals is not satisfactory, and implies a want of principle or uniformity. Thus, in twelve London hospitals the quantity of wine annually consumed varied from 6.145 ounces to 45.248 ounces per patient; spirits from 7.098 ounces to 32.980 ounces per patient; the equivalent of alcohol in wine and spirits varied from 4.537 ounces to 21.117 ounces. The annual average of the equivalent of alcohol consumed per patient is less than in St. George's in seven hospitals, and in four it is higher. We now come to the record of "previous habits," from which it would appear that there is too much homœopathy in the use of much of the alcohol in hospitals to be consistent with sound medical practice.

"Certain patients are reported to have been accustomed, previous to admission, to a daily consumption of three or four pints of beer and two glasses of whisky (age fifty-three); four or five pints of beer, with frequent excesses (age fifty-nine); ten pints of beer and ten glasses of whisky (age twenty-three); hard drinker, chiefly of rum (age thirty); indulged in great excesses, often drinking two bottles of brandy a day (age forty-three); eight pints of beer daily (age forty-two); four pints of beer, with excesses (age thirty-eight); eight pints of beer daily (age forty-two); five pints of beer, with excesses (age thirty-eight); three glasses of whisky (age thirty-four); one pint of beer and six glasses of whisky, with excesses (age forty-five); eight pints of beer, with two pints of gin or whisky (age forty-three); one or two pints of beer, with ten glasses of spirits (age thirty-six); up to ten or twelve pints of beer, and four glasses of whisky (age twenty-two); twelve pints of beer and five glasses of gin, with excesses (age forty-one); from eight to ten pints of beer, and sometimes a pint of gin (age thirty-nine); from sixteen to twenty pints of beer and one glass of spirits (age fifty-four); described himself as a hard drinker of wines and spirits (age twenty-two); twelve pints of beer and eight glasses of spirits (age thirty-eight); ten or twelve pints of beer, and from a half to one pint of gin (age fifty-five); one pint of beer, with three-quarters of a pint of gin daily, with frequent excesses (age forty-five); one to two pints of beer and one pint of sherry (age fifty-three); one bottle of claret (age thirty-nine); one gallon of beer frequently (age thirty-three); beer very freely (age thirty-four); four pints of beer and much spirits (age thirty-nine); from three to four pints of beer, and from one to twelve glasses of rum (age fifty-four); seven pints of beer and seven glasses of spirits (age forty-one); drunk three times a week (age thirty-six); a confirmed drunkard (age thirty-three); immense quantities of whisky (age forty-five); twelve to fourteen pints of beer, and a variable amount of rum (age thirty-one); ten pints of beer and a pint and a half of rum (age forty-five); the largest consumer of beer—*never exceeded* twenty-six pints a day (age thirty-five); the largest consumer of spirits—took twenty to thirty glasses of gin daily (age thirty). Some of these patients are said to be 'gouty.' Only one total abstainer can be discovered."

The record is a striking one in its revelations. Not the least interesting part of it is the ages of the patients. The absence of high ages is noticeable. When we are asking the public to support the hospitals, as we very seriously do, it is only right to urge that hospitals shall make it clear to such patients as come to them suffering from one or other of the various forms of alcoholism that their diseases are largely self-induced. Patients who would resent a hint of that kind from any other quarter will often take it from a physician.

It is a matter, too, for serious consideration whether the large amount of money spent by hospitals on beer and

other stimulants, besides conveying wrong teaching to patients, might not be spent to more advantage in procuring other forms of food. The public, if asked to be less stinted in its gifts to hospitals, and indeed to give generously, has a fair right to ask that hospital money shall be administered wisely.

WE did rightly in not expressing too confident an opinion on the probable length of the session of the Council. Judging from the proportions of the first day's programme and the resurrection of the subject of preliminary education, it is quite possible that the Council may sit for a week, though to common and outside observers there never has been a season in which it would have seemed more proper for the Council either to forego its meeting or to resolutely confine itself to formal business and a two days' session. Nothing could be more quiet or unexciting than the opening of the address of the President, the only mischievous portion of it being that in which he informs his colleagues that for one session at least they may sit in peace without fear of distraction at the hands of either Government or medical reformers. Dr. STORRAR at least seems to have taken this seriously, and to have set himself to find out a subject admitting of endless debate and of a certain amount of harmless agreement amongst the members of the Council. Whenever the Council has nothing very definite to do, the subject of the Preliminary Examination of medical students is sure to turn up. Do all the bodies insist on a certificate of having passed such an examination prior to the commencement of medical education? What subjects should be included? Who should conduct the examination? Should medical examining bodies examine also in Arts, or should the examination in Arts be left entirely to the national educational bodies? Should Greek be included? Should it be compulsory or optional? How shall the Council define what it requires of students in the way of knowledge of elementary mechanics, of solids and fluids, meaning thereby mechanics, hydrostatics, pneumatics, and hydraulics? These are questions which the Council has debated since its creation. The historical sketch by Dr. STORRAR of the vicissitudes of such questions in the Council sounded more like the adverse evidence before the Select Committee of Parliament than the opening of a grave and practical discussion. There was something really ridiculous in the way he showed how the subject was constantly turning up, and never advancing to a satisfactory settlement, and we must confess there was something almost audacious, if such a quality could attach to so modest a man as Dr. STORRAR, in gravely taking up an afternoon in such retrospect, and starting the Council on a discussion which can have no other effect than to illustrate for the twentieth time its impotence and inefficiency. We are not differing from Dr. STORRAR in his lament over the unsatisfactory arrangements for testing the preliminary education of those wishing to become medical students. On the contrary, we largely agree with him, and we think that in his speech he threw light on this subject. His allusion to the action of the College of Surgeons, for example—which, while ostensibly committing its Preliminary Examinations to the College of Preceptors, retains the right of saying how many marks, or rather how few marks, shall be regarded as sufficient, and

showing a disposition to be contented with a very modest number; this was a very serious matter. He was very effective too, in showing how much rivalry and jealousy there is among the bodies in Scotland in the matter of the Preliminary Examinations, and how even the Edinburgh University, under certain circumstances, accepts the examination in preliminary subjects of other bodies, such as the Edinburgh College of Physicians and Surgeons. But after allowing all this we cannot but admire the coolness, and even boldness, shown by Dr. STORRAR in initiating another discussion on Preliminary Examinations, seeing that he has been doing identically the same thing, with so little result, for exactly twenty-one years. Two full days have been occupied at the time of our writing over the mere proposal to refer the subject of Preliminary Examinations to a Committee, at a cost of £200 a day. Independent of this perennial proposal, there are several motions on the programme dealing with various questions of detail in regard to preliminary examinations, mostly by new members. It is not intelligible how members of the Medical Council, under existing circumstances, so vividly described by Mr. SIMON, can deliberately repeat fruitless discussions which have been the staple of the Council's work since its creation. If the main recommendations of the Council for the last twenty-one years, in favour of independent preliminary examinations, have been disregarded, is it to be thought that it can speak with any influence just now? It cannot do so, and the Council shows a sad want of dignity and self-respect in spending so much time and money over a subject on which it has already expended so much time. Dr. ANDREW WOOD even distinctly intimated the intention of the body he represents to defy and disobey the Council. Under these circumstances, and considering the fact that the Council is accused before Parliament of inefficiency, it will act with most credit to itself in despatching formal business only and separating. To continue deliberations which are so sure to be useless, which are so costly, and which are the mere repetition of discussions that have recurred at intervals of two or three years for twenty-one years, is to favour the advocates of medical reform with an argument for which they cannot be sufficiently grateful.

Annotations.

"Ne quid nimis."

INTERNATIONAL MEDICAL CONGRESS.

ALTHOUGH little or nothing has been noised abroad of the prospective arrangements for the meeting of the International Medical Congress in London in August, 1881, some preparatory steps have been taken. A subscription has been opened, and after an application made to some of the leading members of the profession, a goodly sum of money has been promised, sufficient to ensure that the Committee will not be hampered for lack of funds. Burlington House has been secured for the meetings of the Congress; and it is confidently anticipated that its reception will be in every way worthy of the profession in this country. The Executive Committee has nominated Sir W. Gull, Mr. Erichsen, and Dr. Matthews Duncan, as Presidents of the Medical, Surgical, and Obstetric Sections. These appointments will doubtless be a good deal canvassed, and, as must always be

the case where a selection has to be made from many worthy of the position and its honour, opinion will be somewhat divided as to the wisdom of the choice. While confessing that perhaps the selection is not in every case the best possible, we are confident that each section will have a president not only worthy of his position, but adding lustre to his chair. They are men of whom British physicians and surgeons may be proud; and we feel that it is needless for us to claim for them that support and sympathy from their fellows, which will be as essential to the success of the Congress as it will be spontaneous.

THE DANGER OF ESMARCH'S ELASTIC BANDAGE.

THE use of Esmarch's elastic bandage is one of the most serviceable of the modern improvements in operative surgery; by its means not only is loss of blood prevented, but many operations can now be conducted with a deliberation, and therefore a precision and skill, that was formerly unattainable. When Dr. Reid conceived the idea of utilising this bandage in the treatment of external aneurism, and showed by a very successful case that his idea was eminently practical, the field of usefulness of the elastic bandage was immensely widened. Nearly thirty cases of aneurism in which this treatment has been used have already been recorded, two-thirds of which have been successful; doubtless there have been many other unrecorded cases. Hitherto no ill results have been recorded, if we exclude Mr. Bryant's case, in which gangrene of the foot followed, but possibly was not caused by the use of the bandage. Dr. Robert F. Weir of New York, however, has had the misfortune to lose a patient while undergoing this treatment. The man was a negro, aged thirty-two, with a large popliteal aneurism completely filling the ham. The elastic bandage and tubing were applied in the usual manner, and after two hours and a half the tubing was removed and replaced by a Signoroni's tourniquet, this and the bandage being removed after another hour and fifty minutes. Two days later, as the aneurism was not consolidated, the treatment was repeated, the tubing being left on two hours and fifty minutes, the bandage alone four hours longer, and a Signoroni's tourniquet at the groin a further half hour. The next day the pulse at the wrist was found to be nearly absent and very weak and irregular in the femorals, although there were no other signs of shock, and in spite of careful stimulating treatment, he sank and died twenty-seven hours after the discontinuance of the compression. At the autopsy the aneurism and the artery beyond it were found filled with soft recent coagulum; the heart especially on the right side was found on microscopic examination to be "distinctly fatty." The risk of overstraining a weak heart has been noted and often commented on by surgeons as a drawback in the use of the elastic bandage, but we believe we are correct in stating that this is the only recorded instance in which this danger has been experienced. Dr. Weir rightly observes that it was a pity the bandage was retained on so long; for although it might not completely arrest the circulation, it yet allowed only a small quantity of blood to circulate in the limb. But this case suggests two other precautions which no doubt have been often taken, though not expressly noted. One is not to continue the bandage above the aneurism and interfere with the general blood pressure more than is actually necessary; if the bandage be put on up to the aneurism, and then the tubing be applied tightly round the limb immediately above the tumour, the desired condition of the aneurism and adjacent artery, full of stagnant blood, will be obtained; and the application of the bandage up the thigh for a popliteal aneurism is of no advantage, and only occasions additional risk from the greater stress it throws upon the heart. Then, again,

the surgeon should carefully watch the pulse while carrying out this treatment, and at the first sign of heart distress or failure relax his pressure. The bandage is so constantly employed that it is only too easy to forget that in some cases it may be a source of danger. Some may be inclined to think that such a risk lessens the value of the bandage, but we think that it is derogatory to the intelligence of the profession to think so. The most perfect instrument requires intelligent using, and excellence in a remedy for therapeutic application can never compensate for a lack of knowledge as to its applicability. The history of surgery shows only too plainly that what ever has been and still is the great need, is not additions to our mechanical power or skill so much as the knowledge to enable us to use wisely the means already at our disposal. The best surgeons can do most with simplest means.

TEACHING AND EXAMINATIONS IN THE UNIVERSITY OF EDINBURGH.

A CORRESPONDENT, by way of showing the necessity for a one portal system, even as regards universities, points out that the appointment of assessors has not altered the case. He gives an instance, which he says was the common talk of students, in which an assessor in the University of Edinburgh, examining in the practice of physic, put a very proper and straightforward question—which was objected to by the examining Professor on the ground that that subject had not been discussed by him in the course of lectures which the student had attended. The Professor in question, the able lecturer on the Practice of Physic, does not, we believe, as a matter of fact, include the whole range of subjects in one year's course. He takes two years to complete what he has to say on the great theme. We can well understand that Dr. Grainger Stewart's conception of what a university course of lectures on the practice of medicine is such that it cannot be carried out in less than two years. But it seems to us a serious thing that a student might attend one of these courses—all, be it remembered, that is required either by the University of Edinburgh or the General Medical Council—and not hear from his teacher any account of a disease so important, say, as pneumonia. We cannot doubt that an assessor would feel in no way bound to confine himself to subjects treated of in the actual course of lectures attended by the candidate, and that there is an actual error on the part of our correspondent in thinking so. But we think it right to give so much publicity to his notion for the double purpose of pointing out how much even a well-ordered university like that of Edinburgh has to gain from the establishment of a one portal system, which would bring extraneous tests to its work, and of suggesting that one course of lectures should at least cover all that is vital and important in the practice of physic.

SUPPOSED POISONING BY DISEASED HAM.

THE Sheffield papers report the occurrence of a number of cases of supposed poisoning from eating diseased ham, in which upwards of a score of persons have suffered from more or less acute symptoms, and four or five have died. The outbreak is traced to some ham used at a refreshment department at Welbeck, the seat of the Duke of Portland, on the occasion of a sale there. The evidence is, however, of a very contradictory nature. According to some there have been cases amongst persons who had not been at Welbeck, nor partaken of any of the refreshments supplied there. But the majority of the cases are alleged to be traceable to this source, in some cases portions of the ham having been taken away, and when used by others producing severe symptoms. The symptoms—severe colic, diarrhoea, and vomiting—suggested to one medical man the view that it was an outbreak of English cholera. Others have ascribed the disease

to trichinosis, a view not supported by examination of the meat, nor, we think, by the published accounts of the symptoms. It would seem far more probable that the form of poisoning was that which has been much more frequently observed in Germany, arising from some peculiar mode of partial decomposition of the meat; the nature of the poison, the so-called Wurstgift or sausage poison, being as yet unknown. But in the absence of further and more accurate details, we must suspend judgment. The occurrence certainly deserves thorough investigation, and we learn that the Local Government Board has directed Dr. Ballard to visit the locality and make inquiry concerning these cases.

THE PRELIMINARY SCIENTIFIC EXAMINATION.

THE Senate of the University of London, on the receipt of the recommendation from Convocation that the Preliminary Scientific and First M.B. Examinations should be held twice annually, appointed a Sub-Committee to consider the question. This Sub-Committee has grappled with the question of the Preliminary Scientific Examination, which, it recommends, shall be held twice a year. At the same time, it is found necessary to do away with the Honours Examination as it exists at present, and the Committee therefore recommend that honours shall be awarded "upon the aggregate of the marks obtained at the Pass Examination in like manner as at the Matriculation Examination."

The holding of the Preliminary Scientific Examination twice annually will prove a great boon to students, and will encourage a certain number to pursue their career in the University, instead of throwing it up in despair at the first failure, as is now too often the case. The alteration in the Honours Examination will not, probably, have any material effect upon the quality of the work done, although science teachers may urge that the abolition of special honours will take away from students a valuable spur to the pursuit of any special branches of science for which they may have evinced a peculiar aptitude.

It is not necessary to point out that the doubling of the Preliminary Scientific Examination without at the same time doubling the First M.B. Examination, is not of much use in shortening the Medical Curriculum of university students, for it is evident (as was pointed out in the Report of Convocation) that candidates who might pass the Preliminary Scientific Examination in the winter would still be unable to pass the First M.B. Examination until eighteen months afterwards. However, the Senate will doubtless see their way in time to carrying out the suggestion of Convocation in its entirety. The holding of the examinations more frequently will have the effect of popularising the University among the rank and file of the profession, for a reference to the "pass and pluck" list of the College of Surgeons will show that the percentage of failures in Lincoln's-inn-fields is fully as great as in Burlington-gardens, and that the main obstacle at the University is the loss of an entire year, which failure at either of the examinations has hitherto entailed.

Thus the total failures at the First M.B. Examination during the fourteen years 1863-76 amounted to 32.7 per cent.; and the failures at the Second M.B. Examination during the fourteen years 1865-78 amounted to 18 per cent.; or, in other words, out of every 100 men who presented themselves for the First M.B. 68 passed, and of these 68 12 failed to pass the Second M.B., leaving 56 per cent. who presumably took this degree without failure at either examination. At the College of Surgeons, 32 per cent. fail at the Primary Examination, and nearly 40 per cent. fail at the Pass-examination; or, in other words, out of every 100 men who present themselves for the Primary, 68 pass, and of these 68, 27 fail at the Final, leaving only 41 per cent. who take their diploma without failure of any kind. Judging

then by the mere percentage of failures, the professional examinations of the College of Surgeons would appear to be more severe than those at the University of London. This fact shows how fallacious may be inferences drawn from percentage calculations.

WOOLSORTER'S DISEASE AT BRADFORD.

SOME interesting facts have recently been brought to light with regard to the woolsorter's disease at Bradford, which are strongly confirmatory of the previous evidence that this disease is identical with anthrax or splenic fever of the lower animals. Some weeks ago, during the time when several deaths occurred in the neighbourhood of Bradford, one or two cases occurred at Harden Mills, one at least being fatal. A week or two later a cow, which was grazing in a field adjoining the factory, died rather suddenly, and it was at the time suggested that it was a case of splenic fever, but the result of the examination was doubtful. Since that time two sheep, grazing in the same field, have also died rather suddenly, and last week another cow was taken ill and died in four hours. A post-mortem examination made by Dr. Bell of Bradford, Dr. Roberts of Keighley, and Mr. Collins, veterinary surgeon, of Bradford, showed that the animal had died of splenic fever, and portions of the viscera having been forwarded to Dr. Greenfield, at the Brown Institution, he has confirmed this diagnosis. It appears that the soap water used for washing the wool in the factory is conducted direct into the fields, and there distributed by means of trenches cut in the soil. The cows drink the water readily. There seems to be little doubt that the disease is really derived from this source, and this is not only very important as evidence of the infectious character of the wool, but is conclusive proof that the washing is not conducted at a sufficiently high temperature to act as a disinfectant. We learn that two other cows have since died in the same field, with similar symptoms and post-mortem appearances. One or two more cases of the disease have occurred in woolsorters, in one case of malignant pustule the local serum proved to be infectious on inoculation, but the man recovered. There seems every reason to believe that more stringent legislation will be the only means of checking the disease, the recent outcry having been apparently ineffectual in enforcing preventive measures.

DEATHS IN PRISON.

WHEN the dietaries under the New Prison Act of 1877 came into operation, in May, 1878, we pointed out that the dietaries for short-term prisoners were much too severe, and whilst finding no fault with the theoretical construction of the dietaries for prisoners undergoing sentences of more than two months, we stated our opinion that the effect of the new scale on the health of the prisoners should be carefully watched. The experiment has been made; and, apparently, in the case of the Coldbath Fields Prison its effect on the health of the prisoners has not been carefully watched, for the result has been an unparalleled mortality among the short-termed prisoners. Soon after the introduction of the new dietaries a great scandal was occasioned by the death of the prisoner Nolan under circumstances which drew forth a severe censure on the prison officials from the coroner's jury who inquired into the case. So strongly was the public feeling roused on this occasion that Government felt it their duty to institute an inquiry as to the circumstances of the death, and the President of the Royal College of Physicians, Dr. Bristowe, and Dr. Guy were appointed to draw up a report. As, however, we pointed out at the time, the report of these gentlemen was very far from satisfactory. They acquitted the officials of all blame in the matter from the *ex parte* statement of these gentlemen. They reported that the cells were well ventilated and sufficiently warmed,

though from their report we do not gather that they tested this point themselves. Nor do they appear to have watched the effect of the dietaries on other prisoners undergoing sentence during the period of their inquiry. We commented severely on the shortcomings of the report at the time of its issue; and if anything were wanted to give point to that criticism, the continued excessive mortality among the prisoners of the Cold Bath Fields Prison has supplied it. The blame, however, cannot altogether be placed on the committee, although they performed their duties in a somewhat perfunctory manner, but on those who were responsible for its construction. An old Prison official, whose inclination and ideas would be controlled by past associations, and two physicians engaged in purely consulting practice, were certainly not proper persons to entrust such inquiry to. The committee ought, as we pointed out at the time, to have consisted of those persons specially skilled in such inquiries. Should another inquiry take place, which we believe likely to be the case, we should advise that the committee should be selected from those members of the profession who have devoted themselves to questions of hygiene, from professed physiologists, and from those who have paid considerable attention to the question of diet and the construction of dietaries. The inquiry ought to be extended over several months, and each prisoner admitted should be carefully examined on entry, his past history recorded, and daily observations made as to the physiological and pathological effect that low diet, seclusion, and hard labour had on prisoners drawn from various grades of society. Such a report would not only be a valuable contribution to medical literature, but would satisfy the public mind that the whole question of the hygienic and dietetic management of our prisons had received the attention of those best qualified to give advice in the matter.

THE THERMIC EFFECTS OF CEREBRAL LESIONS.

THE depression of temperature which follows acute cerebral lesions in man, occurs also in other animals under the same conditions. M. Couty, experimenting upon monkeys at Rio, has found that, after gentle anaesthesia, the exposure of the sides of the brain, followed by stimulation of the fronto-parietal zone, suffices to cause a considerable depression of the temperature of the body. The fall is at first slow, then more rapid, and attains its maximum in from two to five hours. It may afterwards fall and even give place to a rise, but in most of the experiments the animal died during the period of depression. At the moment of death, which was due commonly to arrest of the respiratory and cardiac movements, instead of 37.9° to 39° C., the ordinary temperature of the animal, the rectal temperature was from 34° to 29°, and in two cases 26° to 25.4°. Thus the depression may occur as a result of slight injuries to the brain even in an animal comparatively high in the scale, and a very low temperature, thus produced, is not absolutely incompatible with life. The effect, so marked in monkeys, is scarcely to be observed in dogs, which commonly survive the initial disturbances, even if the lesion is considerable. When, however, death occurs during the initial period it is always preceded by the depression of temperature. At the commencement of the fall all the functions of the animal appear to be unaffected—the creature is merely weak and apathetic. The circulation is then altered; the pulse ceases to be perceptible, and any spontaneous movement seems impossible. It still moves, however, if excited to do so, and can walk and defend itself. Later, this susceptibility disappears, often rapidly, and external stimulation only causes irregular reflex movements. Strong faradisation of the sciatic nerve is necessary to cause movements of all four limbs, and ultimately even this fails. Then the respiratory and cardiac movements stop. During

these phenomena the changes in the cortical excitability were carefully studied. It was found to be scarcely, or not at all, lessened during several degrees of depression of temperature, even when the animals were comatose and without spontaneous movements, and the excitability continued in characteristic form, although lessened in degree, even when the pulse could not be felt and the temperature of the brain was only 34° to 30°C. Still later, however, the excitability became limited to a small number of points, and much stronger currents caused only movements which were less numerous and complicated. Only when the reflex action of the spinal cord disappears entirely does faradisation cease to affect the cortex. In one case, however, even two minutes after the respiratory movements ceased, there was still an excitable point on the brain. This correspondence in the excitability of the brain with that of the cord, and the persistence of the former after other cerebral functions are lost, are remarkable facts.

PROSECUTION UNDER THE APOTHECARIES ACT.

THE *North Cheshire Herald* gives full particulars of the prosecution of Mr. William Lewis Smith of Hyde, formerly with Mr. Bécroft, for practising as an apothecary without any evidence of qualification of a medical or even a pharmaceutical character. Mr. Scott, of the Common Law Bar, London, instructed by Mr. Pridham of Bedford-row, London, and Mr. J. H. Brooks of Hyde, were for the plaintiffs. Mr. Smith would seem to have been a Sunday school teacher and an ardent worker in a mission-room in the town, and even a charitable and kindly man. But there was ample evidence of his attending many cases, and even grave ones, not a few of which terminated fatally. In these he gave a sort of certificate of death. He charged, too—formerly “for attendance and medicine,” but latterly his bills were made out “for time and trouble at your request, and for medicine supplied.” The judge directed that if the jury thought that in these cases defendant inquired into the symptoms, felt the pulse, examined the tongue, and prescribed medicines, their verdict must be for the plaintiffs. After a short consultation, they came to a verdict of £20 for the plaintiffs. The verdict is a most proper one, and so good a man as Mr. Smith should see that he was acting a false part in Hyde in undertaking grave medical duties without any medical qualification.

THE ST. PETERSBURG INSTITUTE OF ANATOMY.

WITH the termination of the session 1879-80, the Institute of Anatomy attached to the University of St. Petersburg has completed the twenty-fifth year of its existence. The institute was established in 1855, and placed under the special direction of Professor Gruber. Since its foundation 6265 second-course students have studied practical anatomy there, and, exceptionally, several third-course students. Moreover, 202 private individuals have attended the institute, also numerous aspirants to military surgeoncies, candidates for the diploma of doctor of medicine, and officers of health, making a grand total of 10,251.

The number of bodies placed at the command of the institute during the twenty-five years amounted to 20,338, of which 13,985 were subjected to dissection, and the remainder were distributed to other chairs of the Academy, also for the use of the students in the more advanced classes of medicine for instruction in practical surgery.

Professor Gruber and his disciples have published within the period under consideration 422 works (*brochures*) on anatomy (391 having been written by the professor himself), and the museum belonging to the institute, and founded by Professor Gruber, contains 6000 specimens of different skeletons.

KOLPO-CYSTOTOMY BY GALVANO-CAUTERY.

UNDER this long and obscuring name an operation for the relief of chronic cystitis is rather widely practised in America. At present the conservative spirit of British surgery has been too strong to allow of its general adoption in this country, although there are cases in which it is both justifiable and very successful. The object aimed at is to allow the urine to escape from the bladder into the vagina at once on its escaping from the ureters, and thus give the inflamed viscus entire rest while the irritating secretion from its own walls can in like manner flow away at once. It is obvious that an operation attended with such disagreeable and distressing results as the constant flow of urine and muco-pus through the vagina should not be lightly undertaken, and we hope Dr. Byrne of Brooklyn is not expressing the general opinion of American surgeons and gynaecologists when he states, or rather implies, that the operation is required in all cases of well-marked chronic cystitis. Dr. Byrne states that he has "never seen permanent, and seldom even temporary, relief follow the use of acid, alkaline, anodyne, or other vesical injections in the treatment of well-marked chronic cystitis." Unless "well-marked cases of chronic cystitis" differ a good deal on the two sides of the Atlantic, we cannot help thinking that the reputation of a sound and justifiable surgical proceeding is being endangered by too frequent and indiscriminate performance. The operation is performed with scissors by Dr. Emmet, and Dr. Bozeman excises a large circular piece "the size of a silver dollar"; but Dr. Byrne has recently described in the "Gynaecological Transactions" a method of operating with the galvanic cautery, which seems to be an improvement on either method, for, without much destruction of tissue, he secures a wound not very liable to cicatrise. He uses an ingenious "vesico-vaginal guide forceps," one blade of which, deeply grooved on its under surface, is passed into the bladder through the urethra, and is pressed into a fenestrum in the flat vaginal blade. The heated platinum knife is then made to cut its way through into the groove of the vesical blade. The wound left is about an inch in length, and contracts to one-half in four or six weeks.

THE GRANT COLLEGE MEDICAL SOCIETY.

THE Grant College Medical Society, Bombay, has been holding a series of extraordinary meetings for the purpose of considering the regulation of the medical profession in that city and island. At a meeting held on the 23rd March, resolutions were passed to the effect that the Government be moved to pass a Medical Registration Act for Bombay similar to that in force in England, and that a committee be formed to examine the English Act and to see how far the assimilation may be carried. At a subsequent meeting the report of the committee was brought up, and the following recommendations of the committee, with certain modifications, were adopted:—

"1. That the Government be asked to introduce an Act into Bombay similar in its working to that in force in England, entitled 'An Act to regulate the Qualifications of Practitioners in Medicine and Surgery.'

"2. That the committee is respectfully of opinion that the following provisions, with certain modifications of that Act, are applicable to the medical profession in Bombay, and are calculated to advance its welfare and secure its position—viz., those contained in Clauses 1, 10, 14, 15, 26, 27, 29, 30, 31, 32, 34, 35, 36, 37, 39, 40, and 45, which provide for the formation of a register of qualified practitioners, and define the privileges of those so registered.

"3. That the committee is respectfully of opinion that a clause somewhat similar in its action to that of 17 should be included in the Act, which would provide for the registration of certain medical practitioners in Bombay of long standing, who, though not holding diplomas, may be considered qualified to practise medicine and surgery."

At the meeting in which these recommendations were adopted, Clause 3 of the Medical Act was added to the clauses mentioned in the second recommendation. A resolution was also adopted, on the motion of Dr. Blanc, seconded by Mr. Succaram, that the President of the Society (Mr. J. C. Lisboa), Dr. Cook, as the Principal of the College, and the secretary (Dr. C. F. Khorg), should address the Government on the subject, and request the favour of an interview with His Excellency the Governor, in order to lay the matter before him.

THE RUSSIAN RED-CROSS SOCIETY.

AT a meeting of the Committee of the Russian Red-Cross Society, held in St. Petersburg on the 17th ult., His Imperial Highness the Grand Duke Serge Alexandrovitch in the chair, a report of the proceedings of the Society for the year 1879 was read and adopted. From this report it would appear that the activity of the Society had been considerably extended. In addition to the assistance given to the wounded and to the widows of soldiers killed in the late war, it had been possible to afford help to the victims in several public calamities, as, for example, from the great fires at Orenburg and from the prevalence of diphtheria in many districts. It was proposed during that meeting to convert the Marie Asylum, established temporarily for the children of officers killed in the late war, or who had died of wounds received in its course, into a permanent institution, and to this end 22,500 roubles had been subscribed.

EXPLOSIONS OF GAS.

THE explosion near Tottenham-court-road should direct attention to the peculiar properties of the body formed by the admixture of gas with atmospheric air in certain not very well-defined proportions. A series of experiments made some years ago with Davy lamps brought to light certain strange features in the behaviour of an atmosphere into which common coal gas was gradually introduced. In the case of this deplorable accident the gas was found to have entered mains which already contained air, and the process being somewhat slowly conducted, it seems probable that the properties of the mixture were such as to render it highly explosive throughout a considerable length of pipe at the time when the light was accidentally or carelessly applied to a branch pipe. The inquiry which will be prosecuted should take the form of a scientific attempt to discover, as precisely as may be practicable, the conditions of the admixture, and it should be carried far enough to ascertain if there is not some better mode of introducing coal gas to closed vessels of large size than that which is commonly adopted. In the case of a small pipe or vessel it may suffice to allow the explosive mixture to escape in due course by the ordinary outlets until the contents of the pipes or chambers are wholly gas; but in the case of large and particularly long services special precautions are necessary, and we doubt whether the means commonly taken are sufficient and effective.

ASTROLOGICAL PATHOLOGY.

IT appears that the planets Jupiter, Saturn, Uranus, and Neptune will be in perihelion simultaneously in the fall of the year. This, we are told, has not happened before for more than 1800 years. Moreover, the "star of Bethlehem" will again make its appearance in the eastern horizon in the month of August. These celestial events will mark the completion of one great cycle of 1800 years and the beginning of another; and we are warned that the first decennium of this coming cycle will be ushered in by disastrous outbreaks of pestilence—a veritable saturnalia of death. We are to anticipate, it seems, a recurrence of the terrible pestilences which concurred with the earlier

years of the Christian era, and of which the recent irruptions of plague are alleged to be the forerunners. The astrological forecaster is an Irishman, and it is gratifying to learn that Ireland will probably suffer less from the evils presaged by this portentous conjunction of planets than other lands. Indeed, he anticipates that, knowing this, strangers will flock for safety to Ireland, and by the encouragement thus given to the commerce of the island help to raise her out of the unfortunate slough of distress in which she now finds herself.

THE MEDICAL COUNCIL AND THE PRESENT SUSPENSE IN MEDICAL LEGISLATION.

WE are very glad to see that so important a member of the Council as Mr. Simon has given notice of a motion to urge the Council to make representations to the new Government of the unsatisfactory state in which the subject of medical legislation was left at the dissolution of Parliament. The duty of the Council is most clear. All medical bodies, including itself, are hindered and semi-paralysed by thoughts of change. Everybody feels that more or less change is inevitable, and that it ought not to be delayed longer than next session. The Council will get far more credit by an earnest representation of this kind than by wasting days over the history of discussions on preliminary examinations.

POISONING BY TINCTURE OF ARNICA.

WE hear from Italy of another fatal case of poisoning by tincture of arnica. A man, apparently in perfect health, drank a quantity of tincture of arnica estimated at from two ounces to two ounces and a half. He immediately complained of a sensation of burning at the stomach. Bicarbonate of soda was given, and afterwards some aromatic tincture. By these his sufferings were relieved for some hours, but the pain subsequently returned, and he died thirty-six hours after having taken the poison. This case suggested some experiments as to the irritating character of arnica. An ounce of tincture of arnica was evaporated and yielded an extract, a little of which spread over the skin caused a papular eruption. A larger quantity produced vesication, just as does cantharides. The residue found in the stomach of the poisoned man, evaporated, and then applied to the skin, produced effects exactly the same as those caused by the evaporated tincture.

THE EFFECT ON THE HEART OF PRECEDING INHIBITION.

DR. BROWN-SÉQUARD has made a large number of experiments, upon rabbits and young cats, on the effect of inhibition on the action of the heart. After the introduction of a tube into the trachea he insufflated the lungs in two rabbits at the same time. He opened the thorax, divided the pericardium, and ascertained the frequency and force of the heart's action. In one of the animals, that in which the heart was beating with least force, he galvanised the right vagus or both vagus nerves. Usually, after a variable time, the heart stopped. (Faradisation of the vagus does not, in the rabbit, always arrest the heart.) When it recommenced to beat, he divided the two great arterial trunks which spring from it, in both animals, and then observed the action of the two hearts. That which had been inhibited always contracted much more frequently than that which had not. In five rabbits, for instance, in which there had been no inhibition, 1869 contractions were subsequently observed; and in five others which had been inhibited, the number of contractions was 3240. Moreover, the contractions were much stronger in the hearts which had been inhibited than in the others. In one of the latter, during half the time of the observation, the contractions were confined to the right ventricle. In seven or eight minutes the hearts ceased to beat,

but in two cases the contractions continued longer in the hearts which had been inhibited, than in those which had not. In three others the cessation in the two conditions was simultaneous. In the cats the same difference was observed. The contractions, after inhibition, were 292, as compared with 141 without inhibition. Should this effect be ascribed to the better nourishment of the heart during the period of nutrition? Dr. Brown-Séguard believes not, but promises another communication on the subject.

FRACTURE OF THE NASAL BONES.

A FEW weeks ago we drew attention in these columns to a paper by Dr. Lewis D. Mason, published in the annals of the Anatomical and Surgical Society of Brooklyn, in which he described a new plan of treating cases of fracture of the nasal bones with depression. We then expressed surprise that Dr. Mason had published this paper before he had had an opportunity of trying his method in actual practice. In a later number of the same journal we find the record of a case of compound comminuted fracture of the nasal bones in a boy aged fourteen, which was placed under the care of Dr. Mason. There was considerable flattening of the arch of the nose with lateral displacement, which was corrected as far as possible by manipulation, and an ordinary surgical needle ground to a drill point was then passed through the lines of fracture, and the fragments supported upon it; a piece of thin rubber was stretched over the nasal arch and needle, and the ends of the latter protected by small pieces of cork. The needle was withdrawn on the eleventh day; its presence caused no pain or discomfort. The result, as shown in photographs and described in the paper, is excellent, the contour of the nose being thoroughly restored.

ST. THOMAS'S HOSPITAL.

AN appeal has been made from St. Thomas's Hospital to the Lambeth Vestry for a reduction of the assessment, on the ground of the unsatisfactory state of the hospital's funds and of the charitable work it performs, tending to reduce the poor-rates. The appeal was referred to the churchwardens and overseers, but in the discussion upon it the proposed reception of paying patients into the hospital, with a view of making a profit from them, was referred to in connexion with the appeal, and as adverse to it.

HOSPITAL SUNDAY FUND.

WE have especial pleasure in announcing that, up to the time of going to press with the present issue of THE LANCET, the Hospital Sunday Fund amounts to £29,500, being nearly £5000 more than the sum subscribed at the corresponding period last year.

THE Committee appointed by the Medical Society of London to investigate the question of poisoning by arsenical compounds contained in wall-papers, paints, articles of dress, &c., presented their report towards the close of last session; but they intend still to pursue their inquiries, and have issued circulars to members of the profession, inviting records of cases in which poisoning from these sources has been proved. Mr. Malcolm Morris is secretary to the committee.

A STRIKING instance of the advantages of a Medical Coroner occurred lately in North Wales. Some workmen, digging in an orchard near Abergele, came on some ware containing several bones that proved to be human bones. Great alarm and evil surmises gathered round the discovery, and the good name of the Principality seemed imperilled till Dr. Pierce, the coroner for Denbigh, investigated the facts, and put a few witnesses through an informal examination,

which showed that the bones had been handled and used as by an anatomical student, and that, "within the memory of man," a medical student had lived there.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Session 1880.

Wednesday, July 7th.

THE General Medical Council met, in its thirtieth session, on Wednesday last, under the presidency of Dr. Acland.

Dr. Thomas Banks was introduced by Dr. Haughton as a representative of the Queen's University of Ireland, in the room of the late Sir D. Corrigan.

THE PRESIDENT, in opening the session, referred to communications which had been received from the licensing bodies in reference to education, and the reports of the branch councils upon them. He then said:—"Upon these documents, which have already been unofficially circulated for the convenience of the Council, several notices of motion have been framed. More than one of these notices directly open up the question, on which so much discussion has been raised of late years, of what are the subjects which should be included in preliminary examinations, and, therefore, what should be taught in the schools—as, for instance, physics, geology, zoology, and other subjects. And the further and really more important question is asked, How they are taught, and what is the standard of examination? The Executive Committee reports concerning seventy-two Examining Boards which the Council recognises as giving certificates of proficiency in general education, that they satisfy 'the requirements of the Council with great uniformity.' They conform, that is to say, with respect to the subjects of examination, but how far they are uniform in respect to the answers which may be expected the committee have at present no means of judging. It will be observed that members of the Council are of opinion that notwithstanding the great progress which is known to have been made in the means of educating students, and partly in consequence of it, the extent and quality of the general education given to them needs reconsideration. It will be proposed, therefore, by Dr. Storrar, that the whole subject be referred to a committee. Meanwhile it may be well to observe at once, in favour of this course, that since the time when the Council first laid down the general arrangements which it would recommend in respect both of general education and examination, not only has the subject of general education, as conducted in the higher schools, been reported upon by three Royal Commissions—viz., by Lord Clarendon's in 1864, Lord Taunton's in 1868, and the Duke of Devonshire's in 1874—but that, without doubt, great improvements have taken place in secondary schools and in the school books which are used in them. But still questions of great difficulty remained unanswered; for instance, it is still a matter of debate in the old universities whether Greek shall be a compulsory subject for the Bachelor of Arts degree, and whether those who have degrees in natural science shall have had the same general education as other graduates. And it must be admitted that scientific men are by no means agreed on these points. When this Council has reconsidered its own requirements the schools will, without doubt, know how to meet them. Meanwhile motions will be brought before you, both by Professor Haughton and Dr. Leet, to the effect that Greek be made compulsory on all medical students, so that the amount and character of linguistic studies and examinations, as well as the extent of scientific subjects, proposed for students prior to their professional studies, is again raised. And I must not fail to mention that, whereas on July 17th, 1879, the Council passed, in regard to the subject of elementary mechanics, the following resolution:—"That the subject of "Elementary

Mechanics of Solids and Fluids—meaning thereby Mechanics, Hydrostatics, Pneumatics, and Hydraulics"—be no longer recommended by the Council as an optional subject of preliminary education, but be recommended as one of the subjects 'without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered,' it being understood that the examination in this branch of knowledge may be passed either as preliminary or as first professional, and that it be referred to the Executive Committee to amend to this effect Sub-section 6 of Section 4, and Sub-section 1 of Section 23, of the edition for 1879 of the Council's standing recommendations. The Executive Committee, after discussions thereon at three successive meetings, came, on March 18th, 1880, to the following conclusion:—"That the Executive Committee, having fully considered this resolution in all its bearings, finds that there are such difficulties connected with carrying it into effect, that it deems it right to refer it back to the General Council for reconsideration. The subject of professional studies and examinations will again be specifically brought before the Council. Memorials were laid before you last year suggesting that certain special modes of study should be made compulsory in respect of ophthalmology and gynaecology. You directed that the memorials should be forwarded to all the licensing bodies for their observations. The report from the several bodies will be laid before you, with a report thereon from a Committee specially appointed by the Council, consisting of Dr. Humphry, Dr. Andrew Wood, Dr. Aquilla Smith, Mr. Simon, and Mr. Teale. A further communication of a similar kind on the subject of mental diseases, forwarded on August 4th, 1879, from the Medico-Psychological Association, will be laid before you. The question will thus be re-opened whether it is possible with advantage to the solid acquirements of the student to add more details to those already required in the four years of professional study—or whether more years are, as in some other countries, to be demanded. It remains only as my privilege to add, that which the Council will be pleased to hear, that no discussions on Parliamentary Bills need this year distract them from their appointed and congenial work of superintending the Studies and Examinations that bear on the Profession of Medicine, and of conferring with the great institutions of the nation that undertake the duty of conducting them. Last year there were three Bills before Parliament dealing with these and other subjects. The Government had thought it well to refer these Bills to a Committee of the House of Commons for report, as a means of affording to those who desire to support any particular views on them to express their opinions. The Committee were unable to report either last year, or this year before the dissolution of Parliament. No Bills of this kind are at present in either House, and the Committee is accordingly not reappointed. On the 27th of May the Vice-President of the Privy Council, in reply to a question put to him, stated that during the coming recess the whole question would be considered by the Government. Meanwhile the Council are steadily pursuing the work which Parliament assigned to them, and on which they have been so long engaged. This increases every year in interest and importance. It increases in interest with the rapid advance of purely scientific biological knowledge, and its relations to the prevention and the treatment of disease. It increases in importance, because this very progress—this mass of daily advancing knowledge—makes us all feel the accumulated force of the pregnant words of our old Greek master, Πείρα σφαλερὴ κρίσις χαλεπή. They only who take a superficial view of the present condition of the science and of the practice of medicine think it a light task to say what portions of each are necessary for our younger students—how they should be taught, and how tested. Probably there is no medical institution that is not ready to say that in these days it has learnt much—perhaps not one will aver, it has not something yet to learn. We, too, whether sent hither by a University or Corporation or by the Crown, feel each year the benefit and necessity of that interchange of thought and that united action for the common work of our Profession and of the Nation for which the Council was called into existence."

The Business Committee was then appointed, consisting of Dr. A. Wood (chairman), Dr. A. Smith, Dr. Leet, Dr. Haldane, and Dr. Pyle. The Finance Committee was also appointed, consisting of Dr. Quain (chairman), Dr. Pitman, Dr. A. Smith, and Dr. Scott-Orr.

A communication from the Medico-Psychological Association, recommending that mental diseases be made the sub-

ject of examination for all degrees and licences to practise medicine, was read.

Dr. QUAIN said that the Council could not insist upon the introduction of mental diseases as a subject of examination. He moved that the letter be entered upon the minutes and communicated to the licensing bodies.

Mr. TURNER seconded the motion.

Sir W. GULL and other members suggested that the communication of the letter of the Medico-Psychological Association would amount to a sanction of the proposal, which, it was urged, the Council was not prepared to give.

Dr. HAUGHTON said the subject had several times been brought before the University of Dublin, but the proposal had never been adopted.

Dr. WOOD objected to overloading the medical curriculum with the subject of mental diseases—a subject which ought to be studied after the licence or degree was granted. He moved, as an amendment, that the letter be received and acknowledged, and that the Association be informed that the Council deemed it inexpedient to ask the licensing bodies to make mental diseases the subject of a separate examination.

Dr. BANKS said that the Queen's University in Ireland had had the subject before it, and had come to the conclusion that it could not be introduced into the curriculum without extending the period, which it was not prepared to do.

Sir W. GULL seconded Dr. Wood's amendment.

Dr. HUMPHRY said that mental diseases already formed the subject of medical teaching in the medical schools.

Mr. TURNER supported Dr. Quain's motion, and said he thought it was due to the Association to give the licensing bodies the information which it desired to communicate to them.

After some further discussion, the amendment was adopted by a large majority, and was also carried as a substantive motion.

A statement was received from the Army Medical Department showing the degrees, diplomas, and licences of the candidates for commissions in the medical department of the army who on the 8th of December and on the 9th of February last presented themselves for examination.

Dr. HUMPHRY called attention to the small number of rejections at the examinations, contrasting the result with that which, he said, was formerly a matter of opprobrium, and when the rejections were extremely numerous. He thought that the Council might take some credit for the change that had been brought about. At all events, it had taken place during the existence of the Council.

Sir J. PAGET also alluded to the great improvement that had taken place in the results of the examinations of the different examining boards. Nothing, he said, could be more lamentable than the results obtained some years ago by the examinations of the Army Board.

A table was presented, showing results of professional examinations for degrees, diplomas, and licences granted in 1879 by the bodies named in Schedule (A) of the Medical Act. The table, with certain alterations, was ordered to be entered on the minutes.

Certain tabular returns were received from examining bodies showing how far their regulations and practice in regard to the seventy-two examinations at present recognised by the Council are such as to satisfy its requirements in regard to preliminary education.

A letter was read from the Royal College of Surgeons in Ireland communicating a resolution adopted by that body to the effect: "That the regulations of the General Medical Council respecting the passing by students of 'the preliminary examination' prior to attendance on lectures be adopted by the Council of this College, and that exceptions to this rule be referred to the Branch Council for Ireland."

Dr. WOOD, who characterised the communication as a very satisfactory one, moved that it be entered on the minutes, which was agreed to.

Mr. SIMON called attention to a passage in the communication from the College of Surgeons in Ireland expressing their "regret that the General Medical Council does not take similar strict action with regard to such other medical authorities as are not acting in accordance with the recommendations of the General Medical Council," and asked for an explanation.

Mr. MACNAMARA said it was understood that there were other bodies that had allowed students to commence their medical education before passing a preliminary examina-

tion; and the Council had never taken action with regard to those bodies as it had done with reference to the College of Surgeons in Ireland. He did not desire to name the bodies, but the representatives present would know whether their particular bodies had complied with the requirements of the Council.

Dr. STORRAR called attention to the reports of the Branch Councils on the answers from the medical licensing bodies in regard to the preliminary education of medical students; and moved: "That the recommendations of the General Council for preliminary education and examination be referred to a committee, to consider and report as soon as possible whether any, and if any, what changes may with advantage be made in them." He said that at the last meeting of the Council the subject of education was crowded out by other subjects. A great change had taken place since then, the Government of the country had passed into other hands, and it was not certain whether the present Government contemplated medical legislation at present or in future. What were the Council to do under the circumstances? Ought they to sit still with folded hands, and cease to persevere in the course they had pursued for more than twenty-one years? His belief was that they ought not to fail in their duty, even if the instrument they possessed should prove ineffectual. They ought to persevere until the instrument broke, and Government would be compelled to see that they must help them out of their difficulty. He proposed to confine his remarks to preliminary examination, and to call attention to a resolution passed by the English Branch Council: "That it is desirable that the examinations in general education be left to the universities and such other bodies engaged in general education and examination as may from time to time be approved by this Council, and that it be delegated to the Executive Committee to communicate with the licensing bodies on the subject." Dr. Storrar then gave an historical sketch of the various steps taken by the Council in regard to preliminary education, and the resolutions passed on the subject. He referred especially to a resolution passed in 1857 to the effect that no one should be allowed to enter the medical profession who did not possess an education in Arts equal to that of the national educational bodies (the universities), and to subsequent resolutions recommending the appointment of examiners in Arts in connexion with the licensing bodies, which he considered inconsistent with the position at first taken up by the Council. He complained that no effort had been made to restrict preliminary examination to the national bodies, and stated that in 1879 the number of medical students passed in preliminary education by the national bodies was 252, and the number passed by the licensing bodies or under the control of those bodies was 699. He regretted the position taken by the College of Surgeons of England, whose Arts examinations were conducted by the College of Preceptors. The College of Physicians had given up Arts examinations for fifteen years. The Apothecaries' Societies declined to change its system. In Scotland, out of 517 students on the register, 27 only passed the Arts examinations of the national educational bodies; and 490 passed either the special medical examinations at the universities or the special Arts examinations of the corporations, many of which were rivals to each other. In the examinations of the Colleges of Physicians and Surgeons in Edinburgh, the student who succeeded in certain subjects and failed in others could have the former recorded in his favour, and come up again for the latter—a piecemeal system of examination, which, he said, would be utterly repudiated in England. Dr. STORRAR then alluded to and criticised the arrangements of the Faculty of Physicians and Surgeons of Glasgow; and afterwards passed to the consideration of the examination in the Queen's University in Ireland, as to which he said it appeared that that body still permitted students to enter upon their medical studies without passing an examination in Arts. He asked whether the result originally contemplated by the Council had been obtained. His own impression was that they began in an age of gold and were at present in an age of lead. The preliminary examinations were not creditable to the profession. If he were asked whether good had been done by the Council and by the qualifying bodies since 1859, he admitted that good had been done. He knew from very distinguished professors that the young men who came to the study of medicine were in a far higher condition of preparation than students were formerly in, and were therefore more likely to become efficient practitioners. From the report of the

College of Physicians and Surgeons it appeared that those who passed the best professional examinations were those who had been best prepared by preliminary education, and those who passed the worst were those who had not the use of their own language. But while acknowledging that much good had been done, he contended that all the good had not been done that ought to have been done, and if something was not done by legislation to remedy the evil of competition between the licensing bodies they would fall into discredit, and the whole question of licensing for the Register would pass from their hands altogether. He wished to place the matter as strongly as possible before the Council. His desire was to have all the preliminary examinations conducted by the national educational bodies; to put an end to all remanet examinations; and to raise the question whether it was not possible to interpose between the existing preliminary and professional examinations an examination in science so as to clear the ground for a purely educational study.

Sir W. GULL, in seconding the motion, said he agreed with Dr. Storrar as to the necessity of training the minds of the students, but it was first necessary to make sure that they had any mind at all. They all felt that if the profession was to advance there ought to be better material to begin with. There should be such an examination as would at once cut off 33 per cent. of the candidates. The question had been raised whether, under such circumstances, they would be able to get a sufficient number of able and intellectual men to enter the profession, so as to supply the public with the requisite number of practitioners. He felt assured that they would. A stricter examination would of itself lead to better men presenting themselves, and they would thus gain in the end. He thought that up to sixteen or seventeen, students should be engaged in general education; that the next two years should be occupied with ancillary or preliminary studies prior to medicine; and that then the purely medical studies should be taken up. The universities would be doing a great public service if they would undertake a good deal more of the general and preliminary education, and leave the hospitals to teach the technical part of the profession. The Council were not now perhaps prepared to go the whole way that was required, but they ought to be prepared at least to show the way, and point out to parents and families the proper kind of preparation for the medical profession.

Mr. MACNAMARA maintained that the subject ought to be discussed by the Council, and not referred to a Committee. There had been many references to a Committee in past years, and no good result had followed. The Council might at once go into the whole question, and definitely settle it. He complained that the Council had recognised preliminary examinations of which it could know nothing but by hearsay. Such examinations should, he contended, be visited, and authentic information obtained with reference to them. He desired to contradict a statement by Dr. Storrar to the effect that the Royal College of Surgeons of Ireland gave qualifications to students who had not passed a preliminary examination.

Dr. STORRAR asked if an examination in Arts was passed before the commencement of medical study.

Mr. MACNAMARA said it was passed before the diploma was given.

Dr. STORRAR replied that that was a very different thing.

Dr. HAUGHTON thought that before referring the question to a Committee the Council ought to lay down certain broad principles as affecting the subject of preliminary examination. He amused the Council by reading a letter which he had received from a student in England, who desired to get a certificate from the Medical School of Trinity College, and after inquiring as to the mode of preparation, naively added, "I would rather pay you for a certificate if you will be so kind as to send me one." He contended that such requests would not be made unless there were some bodies in existence that sold their certificate.

Mr. TEALE deprecated the appointment of a Committee for any other purpose than that of formulating the various propositions relating to the subject in order that they might be conveniently brought before the Council at its present meeting.

The debate was then adjourned on the motion of Dr. Banks.

A communication was received from the Privy Council Office transmitting a despatch from Her Majesty's Agent

and Consul General in Egypt, enclosing an extract from the *Moniteur Egyptien* prescribing the regulations under which medical men may exercise their professions in Egypt.

A communication was received from the King and Queen's College of Physicians in Ireland, presenting a return of the candidates for the licences of the College who showed marked deficiency in the subjects of the preliminary examination in 1878 and 1879.

Dr. A. SMITH said this was the only reply received in answer to the request of the Council.

The Council then adjourned.

Thursday, July 8th.

The Council met again to-day, under the presidency of Dr. Acland. The sitting was mainly devoted to the adjourned discussion on Dr. Storrar's motion with reference to preliminary education. Several representatives of Corporations spoke at length in vindication of those bodies from the charges brought against them; and Mr. Teale brought forward an amendment for the appointment of a committee to formulate the various proposals submitted by different members in regard to preliminary examination, with a view to their being discussed by the Council during the present session. Dr. Storrar expressed his concurrence with this proposal, and it was almost unanimously adopted.

After some formal business the Council adjourned.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chester Rural Sanitary District (population 7515).—Dr. Kenyon reports for 1879 a birth-rate of 28.75 per 1000 population (excluding deaths in the County Lunatic Asylum), and a death-rate of 18.6, as compared with 16.8 in 1878. The most noteworthy event of the year was the occurrence of a severe outbreak of enteric fever in the Lunatic Asylum, due, it would seem, to the imperfect drainage arrangements of the building. Dr. Kenyon takes occasion to urge upon householders the importance of giving attention to these matters, and observes that "in a scattered rural district there is much greater difficulty than in urban districts both in discovering and in dealing with sanitary defects, whilst there is often even a greater necessity for efficient action. In regard to the dwellings of the poor very much had been done; but in regard to the best classes of houses, there is in many cases really a far more serious class of sanitary defects, and they are more difficult to discover. Had that thorough examination and process of remedy in the matter of ventilation of drains, disconnexion of waste-pipes, &c., which has been going on systematically for some years in the town, been equally advanced in the rural districts, as the latest result of a most exhaustive inquiry has shown, the direct cause of the worst portion of the outbreak at the Asylum would have been non-existent. This part of the outbreak stood out distinctively from the rest in these special features, which are recognised as those of an outbreak due to polluted water. An overflow-pipe from a cistern used for drinking purposes led into infected drains. Every person in the house except one, who had had the fever previously, took the fever in a very severe form."

Guildford (population 10,000).—Dr. John Morton reports for 1879 a birth-rate of 32 per 1000 population and a death-rate of 19.7, and the latter rate he regards as satisfactory when the severity and length of the winter are considered, the generally low temperature throughout the year, and the great depression in trade, which told upon the working classes. The "satisfactoriness" here spoken of by Dr. Morton must, however, be considered as relative to the present sanitary condition of the town and the principles (or rather want of principles) of the sanitary administration that obtains there. It is quite obvious that Guildford might become a much healthier town than it is if the Sanitary Authority and the ratepayers were willing. Guildford does not appear to have any system of sewerage, but gets rid of its liquid refuse by pouring it into cesspools specially designed

so that their contents shall soak into the subsoil beneath the site of the town. Its arrangements for house-drainage are apparently contrived to secure a fouled atmosphere in addition to the fouled subsoil; and not content with the fouling of the earth beneath the surface, the scavenging arrangements are made so as to perpetuate fouling of the earth upon the surface. Building appears to be on the increase in Guildford, but the Sanitary Authority seem so confident in the healthy position in which the town stands as to hold themselves exonerated from taking any serious systematic measures for maintaining it in a wholesome state.

SCARLET FEVER AT BRIGHOUSE.

Brighouse, in the West Riding of Yorkshire, has been suffering from a sharp outbreak of scarlet fever, and the medical officer of health, Dr. Britton, has presented to the Local Board a special report on the occurrence. The outbreak itself was sufficiently commonplace in its development, extension, fatality, and, unhappily, uncontrollability; but it has given occasion to Dr. Britton to express certain heretical notions on sundry current opinions, which deserve mention. In view of the incidents of this outbreak (and doubtless of previous outbreaks) he observes, "A system of compulsory notification of infectious disease is, in my opinion, a pretty theory, but impossible to be carried out in practice. If it could be done it would be invaluable, but I cannot see how it can." In the outbreak to which the report refers the local medical men rendered willing assistance to the medical officer of health, but then not 10 per cent. of the cases were seen by medical men. Dr. Britton clearly thinks that to require notice from the head of a family, or other persons, of a case of infectious sickness, when this has not been seen and diagnosed by a medical man, is a requirement not worth the paper it is written on. Dr. Britton did not think it advisable for the Local Board to establish a disinfecting apparatus, doubting the utility of this agency. Families there wash their clothes, and would not, according to Dr. Britton, allow them to be disinfected (meaning, doubtless, by heat). But the articles sent to a disinfecting stove are rarely those which can be disinfected by washing (beds, curtains, &c.), and even in Brighouse, we apprehend, beds are not washed. One thing only is to be depended upon in scarlet fever, according to Dr. Britton, for limiting the disease—namely, removal to hospital. But until the law makes it imperative upon local authorities to provide hospital accommodation he sees little hope of their doing so generally. Moreover, he holds it utterly impossible in the Brighouse district to persuade people to send their children to hospital. So that, between the imperfections of the law and the objections of the people, scarlet fever must be looked upon as a necessary occasional incident of Brighouse life (or death, as the case may be). Happily, Dr. Britton's Brighouse experience is not universal.

THE GOVERNMENT AND FEVER IN IRELAND.

Whatever criticism may have to say in regard to Government measures for dealing with Irish social and political problems, and criticism itself will admit that they are problems of extremest difficulty, one act of the Government will meet with universal approval. We have authority for saying that they have sent down a physician of acknowledged ability to examine and report upon cases of fever and other disease in the distressed districts. The physician so appointed is Christopher John Nixon, A.B., M.B. Dublin, physician to the Mater Misericordiae Hospital, and to the Lord Lieutenant. He is well acquainted with fever, and was, we believe, a pupil of Dr. Lyons, now member for Dublin. We received, and we report, this information with great satisfaction. There has been the greatest vagueness in the information gathered up to this time, either as to its extent, or the nature of the cases—typhus or relapsing fever, and whether there is anything really exceptional in the amount or nature of disease in the districts. Mr. Forster has shown his usual good judgment in sending down a capable and independent witness, whose report will be a most material basis for a right estimate of the situation.

THE VACCINATION ACTS AMENDMENT BILL.

The Royal College of Physicians proposes to unite with the College of Surgeons, the Royal Society, and other learned Societies, in protesting against the Vaccination Acts Amendment Bill, introduced by the Government into the

House of Commons.—A deputation from the Metropolitan Vestries and Boards of Guardians had an interview with the President of the Local Government Board on the 5th inst., to take objection to the Bill. The deputation were far from happy in their reasoning against the Bill, their argument being very markedly two-edged. Mr. Dodson replied in substance that in respect to the merits and desirability of vaccination he was in full accord with the deputation, but as to the infliction of multiple penalties the question was one of expediency. The effect of the Bill before the House will be that parents will be liable first of all to a penalty of 20s., under Clause 29, for not taking the child to be vaccinated; there the penalty is inflicted in the first instance. There would also be two penalties and costs, which would not by any means be easy. There would be no inducement to negligent people to disobey the law, and it would compel obstinate people to obey the law; but it would put a stop to those cases of excessive penalties which, he thought, rather tend to disparage the law and encourage resistance to it.—The Manchester Board of Guardians and the Birmingham Town Council have determined to petition Parliament against the Bill.

OVERCROWDING IN WORKHOUSES.

At a recent meeting of the Preston Guardians the fact was disclosed that the old habits of workhouse sanitary mismanagement still linger among us. A letter was read from the Local Government Board, founded upon a report of one of their assistant inspectors, Mr. Stevens, and which stated that that gentleman, visiting recently the Fulwood Workhouse of the Preston Union, had found the following state of things: In the Boys' Itch ward there were sixteen patients in ten beds, and in the Female Itch ward there were eleven beds occupied by twenty-three children with itch and three adults who were not suffering from itch. In the Lying-in ward there were ten beds, occupied by ten women and eight children. The Local Government Board have thought it right "to bring under the special notice of the guardians the crowded state of the wards above referred to, and to request that the matter may receive the attention of the guardians." Such is the courteous phrase in which the Local Government Board deals with a scandalous breach of decency, if not of duty, on the part of a Board of Guardians!

VACCINATION PROSECUTIONS IN MANCHESTER.

At the meeting of the Manchester Board of Guardians on the 1st inst. the Clerk read a return, called for at a previous meeting of the Board, showing the number of persons prosecuted by the Board under the Vaccination Acts 1867 and 1871, for neglecting to have their children vaccinated since the passing of the latter Act. The number of persons summoned was sixteen, of whom six were fined 1s. and costs; one was fined 5s. and costs; one 10s. and costs; and one 20s. and costs. Six cases were withdrawn or dismissed on payment of the costs, and one summons was not served. Twelve children were vaccinated before the summonses were returnable, and one was vaccinated immediately after the infliction of the penalty. One child died shortly after the summons was returnable; one was certified as insusceptible to vaccination; and one was vaccinated two months after the summons. In no case had any person been summoned more than once.

A Parliamentary Paper has been published containing returns relating to the financial position of the Metropolitan Board of Works. An estimate of the expenditure of the Board for the year ending the 31st December, 1880, contains the following items:—Main-Drainage, Thames Embankment, and Works within the Borrowing Powers of the Loans Act, 1869, £140,000; Commons and Open Spaces, £10,000; Artisans' Dwellings, £350,000; Street Improvements under Special Acts, £600,000. The loans to other Metropolitan Bodies, for purposes which doubtless include many sanitary matters, are estimated at £750,000.

The Bristol Board of Guardians has been exercised with the question of the use of stimulants in their workhouse, and have adopted the following recommendation of a committee to report on the subject:—"That all beer and other stimulants ordered for the paupers who act as nurses, or are employed in any unpleasant work, be supplied to them with their meals, and that the paupers be not permitted to take any part of their allowances out of the dining-room; also that the stimulants ordered for the sick paupers be administered

by a paid responsible officer, unless directions to the contrary be given by the medical officer, and that once a quarter at least the medical officer do specially reconsider every case in which stimulants may be in course of administration." One of the members of the Board suggesting that teetotalism underlays the resolution, added that vegetarianism would next have to be considered, and probably the doing away with clothing in the workhouse, after the fashion of an American sect.

The report of the Public Works Loans Board for 1878-79 shows the following items directly relating to sanitary matters:—Sanitary loans recommended by the Local Government Board under Section 243 of the Public Health Act, 1875, £1,637,819; loans under the Artisans' and Labourers' Dwellings Improvement Act (England), £111,546; ditto (Scotland), £115,000; loans to Local Boards and other authorities under the Public Health Act, but not under recommendations of the Local Government Board, £36,379; loans under the Labouring Classes Dwelling Houses Act, 1866, £53,000.

The joint committee of the Mid-Warwick Combination of Sanitary Authorities is to be moved by one of the authorities at their meeting in August, to reduce the salary of their excellent medical officer of health from £800 to £500, apparently on the ground that the sanitary organisation of the district having now been got into good working order by the present incumbent of the post, a cheaper official may serve to keep it going!

Mr. Alexander Brown moved in the House of Commons for a return, in tabular form, of all the local inspections made by the medical inspectors of the Local Government Board from the formation of that Department to the 31st March, 1880. The return is to include a summary of the latest information the Local Government Board may have as to the sanitary state of the places visited.

It would appear that owing to the operation of certain later Poor Law Acts sundry workhouses in Essex are likely to fall into disuse. One—that of Witham—is already deserted, and a conference of members of the different Boards of Guardians in the county was recently held at Chelmsford for the purpose of determining what should be done with the disused buildings.

At the meeting of the Bristol Board of Guardians on the 2nd inst. a motion to appoint a resident medical officer for the workhouse, which was negatived on division by 26 to 2, gave occasion for a very pleasing and general expression of respect and regard by the guardians for Dr. Grace, who has held the appointment of workhouse medical officer for eighteen years.

The Metropolis Water Examiner (Col. Bolton, R.E.) reports of the water-supply from the Thames for the month of May, that at the intakes of all the Companies it was in a worse condition during the latter part of that month than in April. He adds, however, that the filtration of the water supplied by all the metropolitan water companies was generally sufficient.

Terms having been come to between the Liverpool Corporation and the local authorities of St. Helens and Widnes on the Liverpool Water Bill, the Select Committee of the House of Commons on the Bill terminated its labours on the 1st inst., and the chairman (Mr. Sclater Booth) ordered that the Bill should be reported to the House.

The Medical Officer of Health for the City of London, Dr. Sedgwick Saunders, reports the seizure of sixty-three tons of meat in the Metropolitan Meat Market which had become putrid during its conveyance from America to England. The meat was condemned, and at 6d. per pound it represented a loss of £3328.

VITAL STATISTICS.

HEALTH OF LARGE ENGLISH TOWNS.

The rate of mortality in our large English towns still continues exceptionally low. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5239 births and 2722 deaths were registered last week. The births were 54 above, whereas the deaths were as many as 553 below, the average weekly numbers during 1879. The deaths were

within 6 of those returned in the preceding week, and were equal to an annual rate of 18.9 per 1000, against rates declining from 22.7 to 18.9 in the eleven preceding weeks. During the thirteen weeks of the current quarter the death-rate in these towns has averaged only 20.4 per 1000, against 23.3, 22.7, and 22.2 in the corresponding periods of the three years 1877-78-79. The lowest death-rates in the twenty towns last week were 12.4 in Portsmouth, 13.5 in Bradford, 14.4 in Wolverhampton, 15.3 in Nottingham and Plymouth, and 15.7 in Leeds. The rates in the other towns ranged upwards to 21.3 in Salford, 22.9 in Leicester, 23.7 in Sunderland, 24.9 in Norwich, 25.6 in Liverpool, and 29.8 in Oldham. The comparatively high rates in these last-mentioned towns, excepting Leicester, were due to excessive zymotic fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 406, 419, and 432 in the three preceding weeks, further rose last week to 476; these included 134 from diarrhoea, 102 from whooping-cough, 98 from scarlet fever, and 73 from measles. The annual death-rate from these seven diseases averaged 3.3 per 1000 in the twenty towns; it was but 0.7 and 1.2 in Wolverhampton and Portsmouth, whereas it ranged upwards to 7.3 in Salford, and 9.7 in Norwich. Scarlet fever showed the largest proportional fatality in Salford, Norwich, Sheffield, and Bristol; measles in Sunderland, Leicester, and Salford; and whooping-cough in Liverpool. Small-pox caused 14 more deaths in London and its outer ring of suburban districts, but not one in any of the nineteen other large towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the two preceding weeks had been 229 and 237, declined to 216 on Saturday last; 38 new cases of small-pox were admitted to these hospitals during last week, against 50 and 47 in the two previous weeks. The number of patients in the Highgate Small-pox Hospital was 10, against 9 and 11 in the two preceding weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 198 and 176 in the two preceding weeks, were 177 last week, and were within one of the corrected weekly average; 90 deaths were referred to bronchitis and 64 to pneumonia. The annual death-rate from diseases of this class did not exceed 2.5 in London, whereas the rate from the same diseases was equal to 5.0 in Liverpool, and 3.9 in Salford.

HEALTH OF LARGE SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20.9 per 1000, against 20.6 and 20.5 in the two preceding weeks; this rate exceeded by 2.0, or 11 per cent., the average rate in the twenty large English towns. The rates last week in the eight Scotch towns ranged from 14.4 and 16.1 in Greenock and Aberdeen, to 25.3 in Perth, and 36.1 in Paisley. The 99 deaths referred to the seven principal zymotic diseases in the eight towns showed an increase of 4 on those returned in the previous week, and included 25 from diarrhoea, 24 from whooping-cough, 21 from measles, and 16 from fever. The annual death-rate from these seven diseases averaged 4.0 per 1000 in the eight towns, against 3.3 in the twenty English towns. This zymotic rate, which was 0.0 in Greenock, and 2.5 in Edinburgh and in Aberdeen, ranged upwards to 6.2 in Leith and 9.7 in Perth. The 24 deaths from whooping-cough showed an increase on the declining numbers of recent weeks; 12 occurred in Glasgow, 5 in Dundee, and 4 in Edinburgh. The fatal cases of measles, which had been 28, 24, and 18 in the three preceding weeks, rose again last week to 21, of which 13 occurred in Glasgow, 3 in Edinburgh, and 3 in Aberdeen. The 16 deaths from fever showed a further increase upon those returned in the three preceding weeks; 11 occurred in Glasgow, 2 in Leith, and 2 in Perth. The fatality of fever in the eight Scotch towns was again greater than in the twenty English towns, and was proportionately heaviest in Perth. Of the 7 deaths from scarlet fever in the eight towns 4 were recorded in Glasgow and 2 in Leith. The deaths in these eight Scotch towns from acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy), which had been 116, 88, and 79 in the three preceding weeks, increased last week to 91, and were equal to an annual rate of 3.7 per 1000. The rate from the same diseases in London did not exceed 2.5 per 1000. The recent excessive mortality in the Scotch towns has been most

probably due to the high death-rate from lung diseases and from zymotic diseases.

THE HEALTH OF DUBLIN.

The annual rate of mortality in the city of Dublin, which had been 42·5, 39·3, and 32·7 in the three preceding weeks, increased last week to 33·7, a lower rate, with the exception of that recorded for the week ending 26th June, than has prevailed in any week since the beginning of April. The annual rate of mortality in Dublin during the thirteen weeks of the current quarter, without any correction for defective registration, has averaged no less than 36·6. In London, during the same period, the death-rate has averaged but 19·4 per 1000. The 203 deaths in Dublin last week included 53, or 26 per cent., which were referred to the seven principal zymotic diseases, against 53 and 48 in the two preceding weeks; 19 resulted from scarlet fever, 14 from small-pox, 8 from measles, 5 from whooping-cough, and 5 from fever. The annual death-rate from these seven diseases was equal to 8·8 per 1000 in Dublin, against 3·2 in London, and 2·5 in Edinburgh. The fatal cases of small-pox, which had increased in the three preceding weeks from 13 to 19, again fell last week to 14.

HEALTH OF IRISH TOWN DISTRICTS.

The average annual death-rate per 1000, represented by the deaths registered last week in the sixteen principal town districts, was 29·3, that for Clonmel, 4·5, being the lowest; while the highest took place in Dundalk and Londonderry, being 51·2 and 58·9 respectively. The deaths from the seven principal zymotic diseases were equal to an annual rate of 5·5 per 1000.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

COMPULSORY VACCINATION IN FRANCE.

Dr. Prosper de Pietra Santa has addressed a letter to the Members of the Chamber of Deputies on the proposal of Dr. H. Liouville for making vaccination and revaccination compulsory in France, and the scheme of legislation he has formulated on this subject. The learned editor of the *Journal d'Hygiène* heads his letter with the significant motto, "The Cart before the Horse," and he proceeds to show that Dr. Liouville's proposition is not opportune because of the present defective state of sanitary administration in France, the defective organisation of the vaccination service, and the difficulty of procuring trustworthy vaccine lymph. The letter is of interest, not only on account of the particular subject to which it is devoted, but also on account of the insight it gives into the existing state of sanitary organisation in France. Until this organisation is remodelled, and placed upon a different basis to that upon which it now exists; and until definite provision can be made for the expenses which must be incurred for instituting a system of compulsory vaccination, Dr. De Pietra Santa holds the proposition for establishing such a system premature and futile. We here can scarcely conceive of a system of general compulsory vaccination in France, which would not be carried out by the intervention of medical men. One of the most curious parts of Dr. De Pietra Santa's arguments relates to the number of medical men in France with reference to this question. It would seem that (including *officiers de santé*) there is but one medical man in France to every 2600 inhabitants, and that there are no less than 26,697 communes, out of a total of 36,056, in which there is not a medical man resident! Without money and without the materials for a staff, it certainly seems strange, as Dr. De Pietra Santa observes, that a project of compulsory vaccination should be brought forward. There is much to be done, he observes, before France can be placed in a condition for giving due effect to a law of compulsory vaccination, before in fact—reversing the present state of things—the horse can be put before the cart. If Dr. De Pietra Santa had been more familiar than he appears to be with the history of compulsory vaccination in England, he would probably have seen reason to forego a theoretically complete sanitary organisation as a necessary starting-point for compulsory vaccination. He does not appear to be aware that compulsory vaccination here began, as Dr. Liouville proposes it should begin in France, "la charrue avant les bœufs."

THE EPIDEMIC OF FEVER IN MAYO.

In Swinford Workhouse Hospital there were last week upwards of forty cases of fever, the majority of which, however, had been admitted from districts adjacent to the town of Swinford. Two additional deaths have taken place; and it is stated that such is the dread of the disease that the chairman of Quarter Sessions has adjourned the sitting of his court for three months. Strange to relate, some of the schools in the infected districts are not closed, which, combined with the attendances at wakes and funerals, and the general insanitary surroundings of the lower classes, tend to increase the spread of the disease. It appears upon reliable authority that the disease is typhus fever of a rather mild type, although a few cases of a malignant nature have occurred. The disease usually prevails in the districts at present affected at a similar period of the year; consequently, its origin cannot be solely attributed to the want of proper nutriment, but those whose system is depressed by privation and distress, as is well known, are more liable to be attacked than others. The sanitary shortcomings of the poorer classes would scarcely be credited. Collections of waste manure and dirt surround the miserable hovels they exist in, and in the inside of these cabins, which usually consist of one to two rooms, used as day and sleeping apartments, dirt and squalor prevail. Under conditions such as these disease like the present outbreak of fever easily obtains a footing; and the only wonder is that it has not exhibited alarming proportions.

"RUSSIAN TYPHUS" IN LEEDS.

The rivalry between the two great and neighbouring manufacturing towns of Bradford and Leeds is a well-known local phenomenon, but it would appear to have now assumed a strange form. Bradford has the unenviable notoriety of having within it a formidable disease, imported, as it would seem probable, by wool brought from the eastern-most districts of Asia Minor. Not to be outdone, Leeds, it is currently reported, has an outbreak of typhus attributed to infection conveyed in flax imported from Russia, in the same fashion, as one correspondent ingeniously puts it, as the infection of plague was formerly imported into this country in wool! The comparison is an unlucky one, and we shall venture to hope that the reported transmission of infection rests on no better foundation in the one case than the other.

At the recent meeting of the Birmingham and Midland Association of Medical Officers of Health (Dr. Fenton, President), Dr. Strange, of Worcester, read a paper on infantile mortality in that city. The result of special investigations he had made on this subject led him to conclude that the greatest proportion of infantile mortality was in the artisan class. The great bulk of the deaths were inexplicable on the grounds of situation, soil, or epidemic; and condition of life and means of living was no certain test. The great cause was neglect, from the ignorance or poverty of parents. A larger number of deaths arose from the faulty mode of feeding children than all the rest of the causes combined, and many from the improper exposure to cold of the extremities of children, either from the poverty or vanity of parents. In the case of artisans' children the neglect must be involuntary, from ignorance, but in the case of illegitimate children put out to nurse he thought criminal viciousness sometimes came in.

The Earl of Shaftesbury, K.G., presiding at the recent annual meeting of the Society for Improving the Condition of the Labouring Classes, mentioned, among other illustrations of the sanitary value of the Society's labours, the following fact. Speaking of the once notorious Tyndall's-buildings, he stated that in one year, before the Society purchased them, twenty-two cases of fever had been removed to hospital from a horrible *cul-de-sac* there. Since the Society had acquired the property, twenty years ago, and altered it, there had not been a single case of fever in the buildings composing it.

The twenty-first report of the Board of Superintendence of the Dublin Hospitals, recently issued as a Parliamentary paper, refers to the year ending the 31st March, 1879. The patients under treatment during the year numbered 13,480, of whom 11,607 left the wards cured or were dismissed for other causes, and 1025 died—a mortality of 8·31 per cent. of the cases treated to a termination. The average number of

beds occupied daily throughout the year was 86·75, and the average time spent in hospital by each patient twenty-one days. Of small-pox patients admitted to the hospitals receiving this form of disease, the number was 2123, of whom 479 died, a mortality of 22·56 per cent. The report has some important observations on the defective provision in the hospitals for the reception of cases suffering from the violent delirium of drink, and the defective police arrangements for dealing with persons picked up in a comatose condition.

The population of the Zurich canton, wearied, it would appear, by the seemingly endless discussions of the learned and the press on the subject of vaccination, have determined to submit the question of the maintenance or suppression of the operation to popular vote.

Small-pox is reported to be prevalent at Christiania, and tourists are warned against visiting this part of Norway until further and more definite information is received as to the disease.

We understand that another company has been formed for the purpose of utilising London sewage in fertilising farms and market-gardens in Essex.

The reported prevalence of small-pox at Amsterdam has, we understand, been contradicted officially.

THE SERVICES.

THE INDIAN MEDICAL SERVICE.

WE have received numerous communications from India on the subject of the recent reorganisation of the Medical Service. The complaints made with regard to it appear to be that an injustice has been done to the Department by the abolition of the appointment of surgeon-general in the military branch and the suppression of two deputy surgeons-general, and by the adoption of the principle of selection for the administrative appointments instead of promotion by seniority. The first of these grievances has been discussed at some length in the *Englishman*, which seems to be the organ of those adverse to the measure. But, by its own showing, the change has benefited instead of having injured the Department. It concludes a long article by this statement: "It therefore seems that the officers of the Bengal Medical Service are now eligible for promotion to six military deputy surgeon-generalships, four civil surgeon-generalships, and three sanitary commissionerships in all; whereas in 1879 they were entitled to one surgeon-generalship, one sanitary commissionership, eleven deputy surgeon-generalships, thirteen in all." So that the grievance really amounts to this, that in Bengal the Department has lost five deputy surgeons-general by three of them having been promoted to surgeons-general and two made sanitary commissioners—an appointment corresponding in rank and pay with that of deputy surgeon-general! This is a loss of which, we imagine, few departments would be disposed to complain.

The argument—if it can be so called—brought forward in favour of giving the Indian Medical Department a share of the appointments of the military surgeons-general is very peculiar. The *Englishman* states that the Indian service attracts the best students, and that while at the examinations in February last 42 candidates competed for 35 places in the A.M.D., there were 52 for 23 places in the I.M.D. It is difficult to understand how this could be deemed a reason for adding to the attractions of the Indian service at the expense of the Army Medical Department. We should have thought it told in exactly the opposite way, and that additional lucrative appointments were required for the latter. We should be sorry to see any attempt made to level down the Indian service, but we cannot approve the persistent attempts to have it improved at the expense of the British. If there be any real ground for complaint in the fact of all the military surgeon-generalships being reserved for the latter, this should be remedied, but, as we have repeatedly said, such a change can only be made by granting to the Army Medical Department compensation in the form of a share of the civil administrative appointments corresponding to the number of military ones which would thus be taken from them.

With regard to the other ground of complaint,—the adoption of the system of selection for administrative appoint-

ments, instead of promotion to them by seniority,—we can only repeat that in the interests of the public service some such change was requisite to prevent important posts being too often filled by men who might fairly be classed as below mediocrity. The system has been introduced into the Army Medical Department, and we may add, into very many of the other branches of the public service, and although undoubtedly it inflicts a hardship upon individuals, yet the results, as regards the public interests, are such as not only fully to justify, but imperatively to call for its adoption. That it may be liable to abuse must be admitted, but in the present day the force of public opinion and the powerful aid of a free Press will, we cannot doubt, prove an effectual check upon it.

CAN IT BE TRUE?

Our contemporary, the *United Service Gazette*, states that "H.M.S. *Newcastle*, our only training-ship for young seamen, is in so unsatisfactory a state that a very heavy sick list appears to be the normal condition. We hear, however, that her captain has hit upon an expedient for reducing the sick list, to which we might be permitted to draw the attention of the Admiralty, and also that of the Royal College of Surgeons and the medical schools of the country. Sending for the fleet-surgeon, the captain informed that officer, 'I'll take means to reduce it [the sick list]; you and the senior surgeon shall take turns of duty till it is of a reasonable size.' This is a most original and ingenious method of rendering popular a service which, at the present time, cannot get anything like an adequate number of candidates for admission, and of improving the health of a ship's crew. We would recommend the Lords of the Admiralty to institute an inquiry by competent officers—certainly not naval captains—as to the cause of this great amount of sickness, and the most probable means of reducing it. The latter undoubtedly cannot be to confine the medical officers on board till it is reduced. We should not be the least surprised if a careful investigation were to show that the sickness depended on preventable causes quite within the reach, if not actually arising from some crotchet of the captain, who, if the above be true, has not shown himself to be a man of sound judgment and discretion. We cannot believe that Lord Northbrook would sanction such an extraordinary proceeding, and we trust it may be at once brought to his notice."

Correspondence.

"Audi alteram partem."

POISONOUS LEMONADE.

To the Editor of THE LANCET.

SIR,—May I beg to draw your attention in your capacity of guardian of the public health to a wholesale system of poisoning now being practised by certain vendors of cheap lemonade, mostly barrow or peripatetic vendors, but occasionally by owners of ice and lemonade shops. During this summer it has become the practice amongst certain persons of the above-mentioned class to expose lemonade for sale in large glass inverted-bell-shaped vessels, successive portions of lemonade being abstracted by syphonage. The general idea is so good that it would be a pity for its application to be checked through the operation of any unreasonable outcry; but if the syphons now used be not summarily abolished, most serious consequences will follow. Citric acid, as I need not explain to professional readers of THE LANCET, is the acid principle of lemons; equally unnecessary would it be to explain the rapidity of its action on certain metals, especially lead and copper, giving rise in either case to a dangerous poison. Now, the lemonade syphons I have mostly seen are made of ordinary lead gas-pipe, and commonly furnished with an ordinary brass tap. The dangerous result of using a syphon of such kind need not be enlarged upon. The glass reservoir would be invariably found to contain citrate of lead, and a glass of lemonade, passed through the brass tap, would hold citrates of copper and zinc, all dangerously poisonous.

It is not to be expected that private persons, occupied with their own affairs, are to take upon themselves the

gratuitous trouble of redressing public evils; but recently on a Sunday a street case of wholesale poisoning by lemonade syphonage, of such glaring prominence, came before my notice, that I cannot, without a guilty cynicism, forbear to intervene. Outside an Italian ice and lemonade shop I, whilst some twenty paces distant, was struck by the grass-green tint of the lemonade contained in a glass reservoir. Walking up close to it, I was horrified to see a copper syphon tube steeping in the reservoir; and this is not all. The constructor had evidently reflected on the hydraulic conditions of syphonage. He had adapted a spring stopper to the free mouth of the copper syphon in such a way that finger-pressure would at once cause the syphon to flow. The practical result of this arrangement, as will be seen, is that each successive glass of lemonade drawn not only holds the percentage of copper contained in the reservoir bulk of lemonade (dangerously strong already), but an additional portion of higher concentration, locked up in the syphon before it is caused to act. The lemonade was extensively patronised. Standing aside at a distance, I saw more than a dozen customers, each one booked, as I think you will admit, for an inevitable colicky pain at the least—in some cases for actual colic, which probably might be hereafter attributed to the eating of fruit, to atmospheric agencies—in short, to one of many causes not the right one.

Having put you in possession of the facts, it may be deemed worth while to throw down the copper held by a glass of this lemonade, and publish its amount. Either sulphuretted hydrogen or hydrosulphate of ammonia would of course effect precipitation at once, previous neutralisation being in the case of acid copper solutions unnecessary.

I am, Sir, yours faithfully,

June 28th, 1880.

J. SCOFFERN, M.B. Lond.

BLISTER TREATMENT OF ACUTE RHEUMATISM.

To the Editor of THE LANCET.

SIR,—I was pleased to observe in the last number of your journal the remarks made by Mr. Ilott of Bromley, Kent, respecting the value of the blister treatment of acute rheumatism. This plan I had extensively worked out at the London Hospital, and published the results obtained in the reports for 1864.

Treatment is unfortunately very much the subject of fashion, and tried and approved modes of practice are often laid aside and forgotten in the search for novelties. I am glad to find that the notice of the profession is again drawn to a safe and sound plan of treatment which rapidly relieves the pain and fever, and when carried out *boldly and decisively* shields the heart from inflammatory action and permanent structural change.

I am, Sir, yours faithfully,

HERBERT DAVIES, M.D.,

Consulting Physician to the London Hospital.

Finsbury-square, July 3rd, 1880.

ON THE EXCISION OF OBSTRUCTION AT THE NECK OF THE BLADDER.

To the Editor of THE LANCET.

SIR,—Mr. Browne commenced by objecting to Mercier's operation on the broad principle that such operations as "excision of obstruction at the neck of the bladder" were "useless" and "injurious." Finding, however, from the evidence I brought forward that the removal of prostatic obstruction was practised by some surgeons and recommended by others, he shifted his position, objecting now to the operation on the ground of the particular means employed to effect the object, "by passing instruments down the urethra." The principle of the desirability of removing prostatic obstruction, in certain exceptional cases, may now be regarded as established, and whether a surgeon prefer to effect the object by cystotomy, or by perineal puncture and ligature, or by excision per urethram, is altogether a secondary question to be decided by each operator as he may think best. For Mr. Browne to object to an operation because it had in many instances to be repeated, is about as reasonable as if a surgeon were to object to lithotripsy on the

ground that Sir H. Thompson had in so many of his cases been obliged to repeat it. Before commencing my lectures I applied to M. Mercier for recent information regarding his operation. Unfortunately he was absent from Paris and very ill, but promised that he would give it on his return. Within the past few days I have received a letter from M. Reliquet, stating that he had recently performed Mercier's operation in two instances and that the results were "heureux." So much for the operation which Mr. Browne says was abandoned because it was useless and injurious.

On the one side we have positive evidence of the value of the operation afforded; firstly, by a series of cases published by Mercier, *with the names and addresses of the patients*; secondly, by the report of the Académie de Médecine; thirdly, by that of the Académie des Sciences; and, fourthly, by Reliquet's practice. What have we on the other side? The allegations of Mr. Browne, who has failed to produce any facts to support them.

I remain, Sir, your obedient servant,

Portman-square, July 5th, 1880.

W. F. TEEVAN.

THE DISPUTE AT GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I beg to forward a copy of a letter sent by the students to Mr. Brudenell Carter, and to ask you to kindly insert it in the next number of THE LANCET.

I am, Sir, yours obediently,

W. HALE WHITE, M.B. Lond.

House Physician.

The Reading Room, Guy's Hospital, June 6th, 1880.

To R. BRUDENELL CARTER, Esq.

SIR,—We, the undersigned students of Guy's Hospital beg leave to offer you our thanks for your letter to THE LANCET of the 25th ult. We desire to assure you that our demonstration against the Treasurer was undertaken with the greatest reluctance, and only under the conscientious conviction that our justification was in this case perfect. We feel deeply grateful for the sympathy shown towards the staff of our hospital, engaged as they are in a difficult and delicate controversy, to preserve intact the tradition of a school which numbers in its roll the names of Bright, Addison, and Astley Cooper, and to keep their patients from the grasp of a nursing system which in its vaunting self-sufficiency shrinks not from endangering their safety, and utterly destroys the old home comforts of the ward.

We have the honour to be, Sir, your obedient servants,

A. ERNEST MAYLARD, M.B., B.S. Lond.,

Senior House Surgeon,

G. H. RUSSELL, M.B. Lond.,

Senior House Physician,

R. WATTS WHITE, M.R.C.S.,

House Surgeon,

W. HALE WHITE, M.B. Lond.,

House Physician,

J. H. MORSE, M.R.C.S.,

Junior House Surgeon,

J. A. J. HOWELL, L.R.C.P., M.R.C.S.,

Junior House Physician,

T. S. CROOK, M.R.C.S.,

Senior Obstetric Resident,

H. H. STURGE, M.R.C.S.,

Junior Obstetric Resident.

June 29th, 1880.

To the Editor of THE LANCET.

SIR,—In answer to Mr. Larkin's appeal, I would suggest a committee of old Guyites, to demand from the Governors the immediate resignation of both Matron and Treasurer, to restore order; and that the nursing arrangements be placed under the supervision of the Medical Superintendent. If this is refused, try the question in our law courts—"That the nursing arrangements being prejudicial to the care and comfort of the sick in the hospital, are not the Governors acting contrary to the Trust Deed of the founder in allowing such a thing to exist?"

The present state of things has gone too far, and it is the duty of all Guy's men to rally round the staff. A mass meeting would be useless; it must be done by a committee in London, who should act for those in the country.

I am, Sir, yours truly,

C. F. HARDING, M.D.,

Whittlesea, July 5th, 1880. Formerly Birkett & Bryant's Dresser.

"TREATMENT OF HÆMORRHOIDS BY 'CRUSHING.'"

To the Editor of THE LANCET.

SIR,—Mr. George Pollock, in his observations upon the Treatment of Hæmorrhoids by "Crushing," speaks of the pain occasioned by the clamp and cautery operation as "sufficiently severe to occasion much subsequent suffering, and often for some days."

During the last six years I have had the opportunity of watching a very large number of cases operated upon by Mr. Henry Smith for hæmorrhoids, with the clamp and cautery, both in hospital and private practice, and I think it right to state that my estimate of the amount of pain attendant upon this method does not accord with that of Mr. Pollock. I may say at once that the pain is never severe, and that usually it does not last two hours, after which time patients speak of their condition as one of discomfort rather than of suffering.

If I compare the crushing with the clamp and cautery operation on another point—that of hæmorrhage—I find that the latter has an absolute advantage; for Mr. Pollock admits the inefficiency of the crushing process, and recommends the application of ligatures as a supplementary step, whereas the clamp and cautery operation may be said to be free from the complication of hæmorrhage.

Further, I beg to submit the probability that the presence of ligatures in a wound, the tissues of which abound in large veins, exposes a patient to increased risks.

I am, Sir, yours obediently,

A. BOYCE BARROW, F.R.C.S., M.B.,
Pathological Registrar, King's Coll. Hosp.

Welbeck-street, Cavendish-square.

"TYPHOID FEVER."

To the Editor of THE LANCET.

SIR,—I have read with much interest the communications in the issues of THE LANCET of December 13th, 1879, and January 3rd last, from Sir J. Fayrer, regarding the existence of a fever in tropical and sub-tropical climates similar in its pathology to typhoid fever, but not due to the same cause.

We live in latitude 28° 43' S.; and as far as my short experience of six years in this part of Western Australia goes, it has convinced me that many cases of the so-called typhoid fever here are not due to typhoid origin.

Amongst my cases of this fever I have had cases brought in from many miles in the bush, and these have been young, healthy subjects, who have been exploring for new squatting country, or else travelling in the bush for other reasons, and the cause has been assigned by them to be due either to sleeping on damp ground, or in damp huts. But in all these cases the symptoms have been exactly similar to typhoid fever, with the exception that I have never found the rash.

In conclusion, I would beg to ask some of your readers, What is the difference between typhoid fever and Colonial fever? I have been told by an experienced Colonial practitioner they are "one and the same disease." If this be so, why should we give typhoid fever another name? But if not, let it be thoroughly understood that Colonial fever is due to another cause.—I am, Sir, yours obediently,

CHAS. BOLTON ELLIOTT,

Champion Bay, Western Australia,
March 23rd, 1880.

District Medical Officer.

"THE LANCET" COMMISSION ON WORKHOUSE INFIRMARIES.

To the Editor of THE LANCET.

SIR,—In the introductory article upon your Commission on Workhouse Infirmarys you refer to some of the causes which render the sick *poor sick paupers*. Might I refer shortly to another cause which frequently comes under my notice?

The sick poor person or his friend applies to the relieving officer for an order of admission to the workhouse infirmary. The officer tells the applicant that the district medical officer, who must recommend the order, has gone for the day (he only sitting in the relief office one hour a day), and

that, therefore, the only thing he (the relieving officer) can do is to give an order for the workhouse, from which he *may* be sent to the infirmary.

This state of matters pauperises the poor sick man at once; because the moment he passes the workhouse gates with his order he becomes a pauper, and because, secondly, he is so often so acutely ill that it is quite out of the question to think of sending him off to the infirmary, putting him to the fatigue of another journey, and he has consequently to remain in the workhouse. On the other hand, should he be sent to the infirmary from the workhouse under the above-mentioned circumstances he is most commonly sent back after he is "cured" or "relieved," or voluntarily returns whence he came—the workhouse. This happens over and over again, and I am convinced from a few years' experience that if many of the cases had not been sent into the workhouse in the first instance, where from unfortunate associations in the house they lose all spirit and even thought of independence, they would not, as many of them do, become chronic paupers.

In my opinion, the remedy for this worse than unsatisfactory state of matters is to be found, to a great extent, in some reform in the system of out-door medical relief; either in appointing the district medical officer or officers to attend at the relief offices oftener than one hour a day, or in appointing one or more medical officers to every union or combination of unions, whose entire time shall be devoted to the requirements of the out-door sick poor.

I enclose my card, and remain yours faithfully,

A MEDICAL OFFICER OF A METROPOLITAN

May 22nd, 1880.

WORKHOUSE.

PARIS.

(From our own Correspondent.)

A FEW days since Dr. Liouville, the framer of the proposed law to make vaccination and re-vaccination compulsory amongst all classes, was heard by the Parliamentary Commission appointed to study the question, and although his project is now stringent (see THE LANCET, April 3rd) it was very favourably received. The last *Bulletin Hebdomadaire de Statistique Démographique* shows that legislative interference in this matter will not be ill-timed. The average mortality of Paris for the corresponding weeks of the last three years was 23·1 per thousand, whereas the week ending July 1st, 1880, gave a death-rate of 25·69. This represents a total of 981, and of these nearly a twentieth (48) were due to small-pox, which has thus been six times more fatal than in the three preceding years, when it only caused $\frac{1}{12}$ of the whole mortality, or 7 deaths in a total of 884. These figures prove the prevalence of the epidemic, and others may be given to show that it exhibits an unusual degree of severity at the Laennec Hospital, where there are special wards for the reception of variolous cases—the mortality amongst the patients admitted is very high. It has been increasing progressively from 10·27 per cent., or one death in 9·63 cases, in 1876, and at the present time it stands at 19·41 per cent., or, in other words, one death in 5·15 cases. Dr. Bertillon, the Director of the Statistical Department of the town, attributes the persistence of the present epidemic to the neglect of re-vaccination; and he points out the immunity which this practice has conferred upon the military. From the 1st of January of the present year the deaths from typhoid and variola amongst the civil population of Paris have been 1043 and 1519 respectively, but the proportion in the army has been very different, 206 soldiers having died of the former, whilst only 3 have succumbed to the latter.

Apropos of small-pox, an interesting communication was made to the Academy of Medicine by M. Léon Labbé on behalf of Dr. Vidal, of Grasse. An infant, whose mother had never suffered from this disease, was born covered with variolous pustules, which appeared to be seven or eight days old. It died in a few hours, and M. Vidal was able to obtain a portion of its skin, which he sent to the Academy. It is still more worthy of note that the father was affected with semi-confluent small-pox in the beginning of December, and that conception took place either at the end of November or the beginning of January of the following year.

Paris, July 7th, 1880.

ROYAL COLLEGE OF SURGEONS.

At a quarterly meeting of the Council, held on Thursday, Mr. John Eric Erichsen, F.R.S., was elected President, *vice* Mr. Luther Holden; and Mr. Erasmus Wilson, F.R.S., and Mr. Spencer Wells, were elected Vice-Presidents. The following re-elections were made:—Drs. Bristowe and Dickinson, Examiners in Medicine; Mr. J. Hutchinson, Professor of Surgery and Pathology; Mr. W. H. Flower, F.R.S., and Mr. W. K. Parker, F.R.S., Professors of Comparative Anatomy and Physiology; and Mr. B. T. Lowne, having resigned the Lectureship of Anatomy and Physiology, was succeeded by Mr. Gerald Yeo. Messrs. Coleman and A. Winterbottom were elected members of the Board of Examiners in Dental Surgery.

The President's Annual Report on the affairs of the College was presented. The President and Vice-Presidents were deputed to join with the President of the Royal College of Physicians and the President of the Royal Society to protest against the Vaccination Acts Amendment Bill, and to seek an interview with the Premier and the President of the Local Government Board. The report of the Erasmus Wilson Fund Committee was received and adopted. A letter on the grievances occasioned by the alterations in the Indian Medical Service was referred to the President and Vice-Presidents, to take such steps thereon as might be deemed desirable.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Saturday, July 3rd, Mr. Mappin inquired whether the attention of the Home Office had been called to the alleged wholesale poisoning at Welbeck, Notts, where several deaths had occurred and sixty persons were reported to be ill; and whether a Government official would be sent to inquire into the matter, as the deputy coroner had expressed an opinion at the adjourned inquest very much in opposition to the medical evidence.—The Under-Secretary (Mr. Peel) replied that the local medical officer of health had been in communication with the Local Government Board, who would send down a gentleman to make inquiries if they thought it necessary. He understood that the inquest was still open, and a medical examination was being made on the intestines of the unfortunate victims of this lamentable occurrence. He would be able to give further information on the subject when he had seen the President of the Local Government Board.

In Committee on the Irish Relief Bill, Mr. Parnell spoke of the fever which has broken out in the county of Mayo as spotted-typhus, and attributed it to six weeks' subsistence on Indian meal. He said the people generally were getting weaker and weaker, and bold measures of relief were necessary to prevent famine. Mr. Forster, in reply, took a hopeful view, but admitted that if the harvest proved a failure very exceptional measures of relief would be needed, and for that contingency the Government were prepared. During the progress of the clauses, the Chief Secretary made three important concessions: (1) Postponement of the repayments under the Seeds Act; (2) acceptance of the principle of grants to boards of guardians in aid of out-door relief; and (3) increase of the grant for fishery piers. Notwithstanding some plaintive complaints from hungry members at seven o'clock, who wanted an adjournment for two hours, the sitting proceeded uninterruptedly from twelve at noon to half-past at midnight, and Mr. Forster, who stuck to his task with sturdy determination, assured Mr. Biggar that he would go to church with a clearer conscience now the Bill was through.

On Monday the second reading of the Government Bill for the abolition of cumulative penalties for non-vaccination was further deferred for a week. A petition against the measure was received from the Royal College of Surgeons in Edinburgh. A question was put by Mr. A. M. Sullivan in reference to the grievances complained of by Mr. F. G. C. Shaw, senior veterinary surgeon of the Madras army, to which the Marquis of Hartington replied that the case was dealt with by his predecessor at the India office, Lord Cranbrook, and he had not yet had an opportunity of reading the correspondence. Until he had done so, of course he could

hold out no hope of a reversal of the decision of Lord Cranbrook.

On Tuesday Mr. P. A. Taylor interrogated the Government as to the instructions given for the use of plank beds in prisons. Mr. A. Peel replied in detail, showing that plank beds were recommended by a Select Committee in 1863 for prisoners under short sentences or in the earlier stages of a long confinement; that these recommendations were embodied in the Prisons Act of 1865; that the rule was relaxed in 1868 in favour of women, old men, and children, to the extent of allowing them a pillow and mattress; and that the almost universal use of the plank bed since 1865 justified the opinion that it answered its purpose. The following are the words of the rule now in force:—"That a convicted criminal prisoner shall during the whole of his sentence, when it does not exceed one month, and during one month of his sentence when it exceeds one month, be required to sleep on a plank bed. The prisoner shall be allowed by his industry to earn a gradual remission of this requirement after one month, but after he has earned such remission he shall be liable to forfeit the same on account of idleness, inattention to instructions, or misconduct."

Mr. Joseph Cowen gave notice that on Monday he would ask whether the Government intend to take steps towards the better enforcement of the Canal Boats Act, 1877, so far as it relates to the overcrowding in the cabins and the education of the canal boat children; and also whether the Government intend to bring temporary abodes, such as gipsy tents, vans, shows, and like places under the influence of the sanitary officers, and the children under the power of the Education Acts.

Mr. Alexander Brown gave notice that he would move for a return showing, in a tabular form, in order of years, all the local visitations which have been made by medical inspectors under the direction of the Local Government Board, from the date of the establishment of the Board to the 31st day of March, 1880, with regard to prevalences of disease in particular places, and to questions therewith connected, of defects in sanitary administration, and stating in successive columns in regard to each visitation, as follows:—1. Names and population of the places or sanitary districts inspected. 2. Date of the visitation (or, when several visitations have been made, of the first of them) and name of the inspector. 3. On what ground of complaint, or otherwise, the visitation was ordered. 4. Précis of facts reported by the inspector with regard to the prevalence of disease, and to the existing defects of sanitary administration. 5. Re-inspections (if any) which have since been made in the same areas with reference to the defects of sanitary administration, with the date of each re-inspection and name of inspector. 6. Précis of the latest information had by the Local Government Board as to the sanitary state of the places, and when given, and how authenticated.

On Wednesday, during a discussion on the Sea Fisheries (Ireland) Bill, Mr. Blake, formerly an inspector of fisheries, in an argument for the extension of the system of loans, stated that the fishing industry of Ireland was greatly reduced by the famine of 1847, because eating fish with Indian meal had the effect of giving the people dysentery.—Mr. Finnigan gave notice that he would question the Government concerning a letter from the Bishop of Achroyn to the Archbishop of Cashel, reporting an outbreak of famine fever, and as to the sending of adequate medical relief to the fever districts.—The nomination of the Select Committee on the Contagious Diseases Acts was on the notice paper for Wednesday, but as Mr. Puleston had put down a notice of opposition, and the matter was not reached until just before the end of the sitting, it was necessarily deferred. The following are the names of the gentlemen who will be proposed by Mr. Childers as members of the Committee:—Mr. Cavendish Bentinck, Mr. Stansfeld, Colonel Alexander, Sir Harcourt Johnstone, Viscount Crichton, Mr. Burt, Mr. O'Shaughnessy, Mr. Osborne Morgan, Mr. Brassey, Mr. Cobbold, and five members to be added by the Committee of Selection. Mr. Cavendish Bentinck has given notice that he will move to omit the name of Mr. Brassey, and to substitute that of Mr. Puleston.

On Thursday Mr. A. Brown moved for a return of local visitations by medical officers under the direction of the Local Government Board. No opposition was offered, and the return was ordered. Mr. Forster, replying to questions by Mr. Finnigan and Mr. O'Connor Power, said the Irish Government had sent two medical inspectors from Dublin

Drs. Woodhouse and Nicholson, to the fever districts, and he was expecting soon to receive reports from them. The Government had sent positive orders to the boards of guardians and to the inspectors to see that no money was spared in giving medical assistance, fresh food or change of food, and everything necessary to prevent the spreading of the fever. He was rather more encouraged by an account he had received, and which he would lay upon the table, but he could as yet make no positive statement to the House.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentleman was admitted a Fellow of the College on July 2nd :—

Thomson, John Roberts, M.D. Edin., Bournemouth.

On the same day the following gentleman was admitted a Member of the College :—

Sarell, Richard, M.D. Edin., Pera, Constantinople.

On Monday and Tuesday last the following gentlemen passed the first part of their Professional Examination for the licence of the College :—

George F. Edwards, Joseph R. Locke, Henry Aked Pearson, Henry J. Prangle, Thomas Wakley, Jun.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on Monday, Tuesday, and Wednesday last :—

George W. Ridley, Samuel Brookfield, and Robert Hardie, Newcastle-on-Tyne College of Medicine; Jacob R. L. Dixon, Alfred Thomas, and James F. H. Owen, Liverpool; George D. Mackintosh, Laurence J. Ruck, William Harding, and Roger Kirkpatrick, Edinburgh; Lewis Powell and Thomas Cardwell, Guy's Hospital; Arthur H. N. Lewers, University College; James Robertson, Charing-cross Hospital; J. Gutierrez-Ponce, Paris and New York; David R. Paul, Bengal and Edinburgh; James T. Carter, Halifax and Edinburgh; Harman Risger and Henry H. Parsloe, Bristol; David W. Whitfield, Dublin; Robert B. Carruthers, John T. Smith, John A. Laycock, Edward Kershaw, Alfred B. Liptrot, and W. H. Horrocks, Owens College, Manchester; T. G. Hesk, Sheffield; A. Cowley, G. Hassell, J. R. Stuart, and A. Milne, Aberdeen; F. W. Hewitt, H. Deighton, J. Y. Bostock, Cambridge; A. E. Foster, Leeds; A. H. Hart and W. Dudley, Birmingham; D. P. Edwards, St. Bartholomew's Hospital; R. W. Statham, St. Thomas's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 1st :—

Carnall, Edward, Fowey, Cornwall.
Sellers, William, Radcliffe, Manchester.
Scarth, Isaac, Longsight, Manchester.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week :—

BACHELOR IN SURGERY.—Charles Adams, John Tate Creery, John Loftus Cuppaigide, Charles H. Dixon, Archibald Alex. Hamilton, John Seymour Kane, William Henry Line, Thomas Robt. Lingard, Thomas John Rashleigh Lucas, Edward Erskine Moore, Alexander Baillie M'Kee, Robert James Polden, Chas. Saunderson Purdon.

LICENTATE IN SURGERY.—Brazier Creagh, George Washington.

BACHELOR IN MEDICINE.—Charles Adams, Richard John Baker, John Patrick Barry, Henry Ludovic Clare, John Tate Creery, John Loftus Cuppaigide, Wm. Spear Gordon, Archibald Alex. Hamilton, Fitzgerald Isdell, William Henry Line, Thomas Robert Lingard, Alexander Baillie M'Kee, Robert James Polden, Chas. Saunderson Purdon.

DOCTOR IN MEDICINE.—Travers Barton, Ludovic Jones, John Seymour Kane, Gilbert Lynch, Charles Grove Young.

QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the University on the 21st ult., the following degrees and diplomas were conferred by the Vice-Chancellor :—

DOCTOR IN MEDICINE.—John Howard Battye, George J. Coates, John J. Dinnis, Arthur Hickman, Edward Horan, Daniel Lehan, William J. Matthews, William T. Mullally, Patrick Mullane, James Mullin, John F. L. Mullin, M. W. O'Keefe, Samuel Townsend.

MASTER IN SURGERY.—George J. Coates, John J. Dinnis, Charles Hall, John Hosford, Charles Frederick Knight, John Martin, Patrick Mullane, M. W. O'Keefe, William Smyth, William Stokes, Samuel Townsend, John Wilson, Ralph Worrall.

DIPLOMA IN MIDWIFERY.—George J. Coates, Patrick Mullane, William Stokes, M. W. O'Keefe.

DR. C. H. ROBINSON has been elected a Member of the College of Physicians in Ireland.

MEDICAL MAGISTRATES.—John Turner, F.R.C.S. Eng., has been appointed a Justice of the Peace for the borough of Wycombe.—Samuel Musgrave, F.R.C.S. Edin., factory surgeon and medical officer to the Lisburn Union Hospital, has been appointed to the Commission of the Peace for the Counties of Antrim and Down.

STATISTICAL SOCIETY OF IRELAND.—Dr. Mapother has been selected by this Society as its president, an office formerly held, amongst others, by Archbishop Whately, Judge Longfield, and Lord O'Hagan.

"A LIBERAL GIFT."—Under this heading the *Times* of the 6th inst. had the following suggestive notification :—"A roll of bank-notes, value £500, was dropped into the offertory bag at St. Mary's Church, Chelmsford, on Sunday afternoon, for the benefit of the Chelmsford Infirmary."

The execution of James Sweetland is fixed for the 26th inst., at Newgate. The convict, on receiving an intimation to this effect, was very much distressed, and expressed a wish to see his wife and child and other relatives. Meanwhile a memorial is being prepared by Mr. Ricketts, his solicitor, praying her Majesty to commute the sentence.

MEDICAL SCHOOL OF ROYAL COLLEGE OF SURGEONS IN IRELAND.—On last Monday the prizes obtained during the past Session were awarded as follows :—First year : Austin Cooper, first; Mayer Dutch, second. Second year : M. T. Yarr, first; T. W. Elsner, second. Third year : Humphrey Broomfield, first; Richard Callan, second. Mr. Broomfield, who was first in the third year's course, won the Gold Medal and £15.

THE LATE SURGEON-MAJOR SHEPPERD, A.M.D.—A handsome memorial brass, supported on a slab of black marble, has just been erected in the chapel of the Royal Victoria Hospital at Netley, to the memory of the late Surgeon-Major Shepperd, of the Army Medical Department. The brass bears the following inscription :—"In memory of Peter Shepperd, M.B. University of Aberdeen, Surgeon-Major Her Majesty's Army, born at Leochel Cushnie, Aberdeenshire, 25th August, 1841, who sacrificed his own life at the battle of Isandhlwane, Zululand, 22nd January, 1879, in the endeavour to save the life of a wounded comrade. Erected by his brother officers and friends."

THE GLOBE says : "A Memorial, signed by upwards of eight hundred persons, among whom are the Master of the Rolls, Sir Henry Thompson, Dr. Risdon Bennett (President of the Royal College of Physicians), Mr. Darwin, Professor Huxley, Dr. W. B. Carpenter, the Presidents of the Congregational and Baptist Unions, and the Dissenting Deputies, and the Professors of most of the Nonconformist Colleges, has been presented to Mr. Gladstone, asking for the support of the Government to the motion of Mr. Roundell in favour of the complete abolition of the clerical Headships and Fellowships at Oxford and Cambridge, and on the amendment of Mr. Bryce, for throwing open the Professorships of Hebrew and Ecclesiastical History."

BEQUESTS ETC. TO MEDICAL CHARITIES.—The Mercers' Company have given one hundred guineas to University College Hospital. Mr. E. Hill has given fifty guineas to the Sussex County Hospital, Brighton. H.R.H. the Duke of Edinburgh has given £20 to the Charing-cross Hospital.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BENNETT, W. H., F.R.C.S.E., has been appointed Assistant-Surgeon to St. George's Hospital, vice G. C. Stirling, resigned.

BROWN, Mr. J. M., of the University of Edinburgh, has been appointed Demonstrator of Anatomy in the Owens College, Manchester, vice Mr. H. S. Branfoot, resigned.

BRYAN, C. F., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Workhouse of the Leicester Union.

BURTON, J. E., M.R.C.S.E., L.R.C.P.L., L.F.P.S.G., & L.M., has been appointed an Honorary Medical Officer to the Liverpool Ladies' Charity and Lying-in Hospital, vice Dr. J. H. Wilson, appointed Honorary Consulting Medical Officer.

DICKINSON, Mr. T. V., has been appointed House-Physician to St. George's Hospital, vice Mr. H. T. Griffiths.

FISHER, Mr. F. C., has been appointed House-Surgeon to St. George's Hospital, vice Mr. E. A. Hunt.

GLAISTER, J., M.B., C.M., has been appointed a Resident Medical Officer to the Leeds Public Dispensary, vice Todd, resigned.

HOLLAND, J. C., L.K.Q.C.P.L., has been appointed Medical Officer to the Dungarvan Workhouse, vice Hunt, resigned.

HOLMES, D., M.B., L.R.C.S.E., has been appointed Medical Officer to the Aston Branch of the General Dispensary, Birmingham, vice F. C. P. Howes, resigned.

HOYLE, W. E., M.R.C.S.E., has been appointed House-Surgeon to the Whitehaven and West Cumberland Infirmary and Fever Hospital.

INNES, H. D., M.R.C.S.E., has been appointed Junior House-Surgeon to the Huddersfield Infirmary.

KENNY, M. A., L.R.C.P. Ed., has been appointed Medical Officer to the Selby District and Workhouse of the Selby Union, vice Gray.

LEACH, J. C., M.R.C.S.E., B.Sc., S.Sc.C.Camb., has been reappointed Medical Officer of Health to the Sturminster Rural Sanitary Authority for three years.

LEWIS, C. J., M.R.C.S.E., L.R.C.P.L., has been appointed Resident Surgeon at the General Dispensary, Birmingham, vice J. H. Palmer, resigned.

MILLER, H., L.R.C.P. Ed., M.R.C.S.E., has been appointed Medical Officer to the Hartland District of the Bideford Union.

MONTEITH, J. M., M.B., C.M., has been appointed Medical Officer to the Fourth District of the Bellingham Union.

RYERSON, G. S., M.D., has been appointed Ophthalmic and Aural Surgeon to the General Hospital, Toronto, Canada.

SHAPLEY, F., M.R.C.S.E., L.S.A.L., has been appointed Assistant Medical Officer to the Worsfold House Hospital for the Insane, Exeter.

SUNDERLAND, W., L.R.C.P. Ed., M.R.C.S.E., has been appointed Medical Officer to the First District of the Saffron Walden Union.

TAYLOR, F., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Teignmouth, Dawlish, and Newton Infirmary, vice G. Coutts, M.B., resigned.

WALFORD, E., M.R.C.S.E., has been appointed Medical Officer of Health for the Urban Sanitary District of Ramsgate, at a salary of £150 per annum, vice J. W. Barry, resigned.

WESTMORLAND, Mr. J., has been appointed Certifying Surgeon for Factories for the Collyhurst, Harpuey, and Blackley Districts, Manchester, vice J. B. Pinder, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BROMLEY.—On the 27th ult., at Castle Hedingham, Essex, the wife of John Bourne Bromley, M.R.C.S.E., of a daughter.

CORBAN.—On the 1st inst., at Sunnyside House, Gibraltar, the wife of Surgeon-Major Laurence Corban, M.D., of a son.

DAVIES.—On the 26th ult., at High-street, Newport, Mon., the wife of George A. Davies, L.R.C.P.L., of a son.

EVANS.—On the 5th inst., at Sutton Coldfield, the wife of Alfred H. Evans, M.R.C.S.E., of a daughter.

FERGUSON.—On the 28th ult., at Claremont-square, N., the wife of W. E. L. Fergusson, M.D., of a son (posthumous).

FRODSHAM.—On the 3rd inst., at Denham House, Upper Streatham, the wife of John Mill Frodsam, M.D., of a son.

HENSMAN.—On the 26th ult., at Park-street, Taunton, the wife of William Hensman, Brigade-Surgeon, A.M.D., of a son.

HORNER.—On the 28th ult., at The Gables, Tonbridge, the wife of Arthur Clayton Horner, M.R.C.S.E., of a daughter.

SMITH.—On the 27th ult., at Howard Lodge, Hurstpoint, Sussex, the wife of G. J. Malcolm Smith, M.B., of a daughter.

WELCH.—On the 2nd inst., at Victoria-park-road, the wife of Samuel Welch, M.R.C.S.E., of a son.

MARRIAGES.

HERAPATH—LANE.—On the 24th ult., at St. Mary's, Tyndall's-park, Clifton, by the Rev. W. F. Bryant, M.A., assisted by the Rev. J. Kerry, Chas. Kynaston Herapath, Surgeon, of 11, Brunswick-square, Bristol, only son of the late W. B. Herapath, M.D., F.R.S., to Emily Kate, only daughter of Frederick Lane, Esq., of Lawrenny, Leigh-road, Clifton.

LAWRENCE—HERVEY.—On the 1st inst., at St. Mary's, Hadlow, by the Rev. P. Howard Monypenny, Vicar, Henry Major Lawrence, Esq., L.R.C.P., L.R.C.S., to Emily Alice Hervey, daughter of the late Mathew Hervey, Esq., of Charnwood, Victoria.

ROUGHTON—ROBINSON.—On the 1st inst., at the Parish Church, Streatham, by the Rev. T. T. Griffith, Rector of Teale, assisted by the Rev. W. C. Roughton, Vicar of Great Harrowden, Northamptonshire, and the Rev. J. R. Nicholl, Rector of Streatham, James Wooley Roughton, M.R.C.S.E., L.R.C.P., of Streatham-common, third son of James John Roughton, Esq., of Kettering, to Frances Mary, eldest daughter of Augustus A. Robinson, Esq., of Greta House, Streatham.

DEATHS.

BENNETT.—On the 2nd inst., at Hornsey, Middlesex, Charles Frederick Bennett, M.D., late of Lymm, Cheshire, aged 55.

DOVE.—On the 5th inst., at Stowmarket, Suffolk, Harry Dove, M.R.C.S.E. & L.S.A.L., only son of the late Dr. Dove, of Norwich, aged 30.

ELLIOTT.—On the 30th ult., at Bury Grange, Gosport, John Elliott, Deputy Inspector-General of Hospitals and Fleets, late of Corbo, Clogher, co. Tyrone.

PALSGRAVE.—On the 2nd inst., at Kilburn, John Henry Palsgrave, Retired Surgeon, Bengal Army, aged 78.

SMITH.—On the 2nd inst., at 5, Newton-terrace, Glasgow, Mary Baird, wife of A. Wood Smith, M.D., of the Glasgow Royal Infirmary School of Medicine.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

A COUNTY COURT JUDGE ON MEDICAL CERTIFICATES.

At the Lewes County Court, according to the *East Sussex News*, the Judge, A. Martineau, Esq., thought fit to deliver himself as follows on the value of medical certificates of inability to be present on the part of important witnesses:—"I am sorry to say doctors are most unscrupulous in granting medical certificates. Therefore I place little dependence on these certificates. Anybody seems to be able to get one when one is desirable for convenience sake." This is a most unusual and unwarrantable remark. Proceeding from a Judge in his chair of judgment, and made in the absence of the medical man who had certified it, was, besides being unjust, mean and ungenerous. We shall not insult the medical profession by replying to it. We can afford to rest in the respect of the public, and may refer the Judge for public opinion on his estimate of medical men and their certificates to the excellent article in the *East Sussex News* of June 18th on his libellous words.

Verb. Sat. Sap.—Our correspondent is thanked for his letter; but as the subject has so recently been fully discussed, we think it would be advisable to wait until the operation of the G.O. is more apparent before again taking it up.

Mr. John C. Stanley.—It is not "Cayenne turpentine," but Chian turpentine.

THE DUBLIN DEATH-RATE.

To the Editor of THE LANCET.

SIR,—I notice in your columns that the death-rate in Dublin still continues to be very high—some 40 per 1000 inhabitants per annum. I have also noticed that a great deal of blame has been cast upon the public officials and the medical authorities of Dublin for this sad state of matters.

It seems to me to be very unfair to saddle either of these bodies with a mortality which, as I read it, they have but little to do with. My impression is that the real cause of the overcrowding, fever, and unhealthy condition of Dublin at this moment resides in the extreme poverty—nay, destitution—of some parts of Ireland. Those who, like myself, chanced to see Ireland in 1848 will understand how powerless all hygienic remedies are when poverty is widespread.

I read in a journal the other day that the cost of the food of an in-door pauper in one of the Irish unions was but 2d. a day. When we hear of such misery *within*, what must be the misery *without* the workhouses? I have offered these few words in order to show that there is but little use of scolding medical men or town councils in Ireland at this moment. The question lies deeper than that; but it is soluble.

I am, Sir, your obedient servant,
CHARLES R. DRYSDALE, M.D., &c.

Woburn-place, June 29th, 1880.

A Surgeon-Major, I.M.D.—We do not agree with our correspondent on the question of promotion by selection to the administrative ranks. We believe it to be essential to efficiency. The other point in his letter we have discussed elsewhere. We regret that we cannot find space for his communication.

Mr. Dolan's paper has been submitted to our commissioners.

New-comer.—There is no absolute rule. Custom varies. On the whole, in the country the rule seems to be for the new-comer to call on his medical neighbours. If the patient of another medical man, actually under the medical attendance at the time, seeks the advice of "New-comer," our correspondent should decline to take the case, except on the understanding that intimation is made to the former adviser. It is scarcely his duty in fresh cases of illness to go into the antecedents of his patients, always provided that he encourages patients to continue faithful and respectful to their existing professional connexions in the absence of good reasons to the contrary.

Mr. J. G. Braden is thanked for his communication, on which he will see our comment to-day. The best punishment for so unjust a Judge is to publish his words, and to leave him and them to public censure. Such Judges will not hurt the medical profession.

W. M. N.—Hay and Son, Little Queen-street, Lincoln's-inn-fields; F. Kidston, Duke-street, Union-street, Bishopsgate.

REGISTRATION OF DISEASES IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—I trust that Mr. Howlett's letter on the subject of the Registration of Disease in Hospitals will receive the attention it deserves from those to whom it is addressed—the medical and surgical registrars of London; and that, amongst other good results, it may lead to the fuller recognition of much laborious service which is at present somewhat undervalued.

When it is considered how ample is the material with which these officers have to deal, their position of absolute impartiality and special opportunities of observation, it would almost seem as though it rested with them personally to fulfil one of the main ends for which hospitals exist. The value of the registrars' work is, indeed, so fully recognised, that it would be easy to mention by name those hospitals in London which are distinguished for the completeness and extent of their "post-mortem and case books," as well as those that show but poorly in this respect with records so variously and irregularly kept as to be practically useless.

The systems of registration and nomenclature at present in vogue, although various enough to be confusing, are not so different, as I believe, as to make it impossible to arrive at a common agreement. Such a committee as Mr. Howlett suggests, besides accomplishing this, would give a new vitality and impulse to a department of hospital work which at present is hardly appreciated. But, besides this, an annual conference of medical and surgical registrars would assist in directing and limiting a labour that is often spoken of as being too wide and miscellaneous. Some common method and motive of work might be resolved upon prospectively from year to year; the observation, I mean, during that period, of some particular subject of clinical interest in especial. Is it too much to say that the authority of records so collected, where there is no hypothesis to uphold and no personal element to satisfy, would be greater than that of any individual collector, however candid and honest?

As a specimen of what may be done in this way, I may refer (with the satisfaction as well as the shame of one who occupied the same post less worthily years ago) to the medical report of Dr. Owen published in the last volume of the St. George's Hospital Reports. Contrast with this the tabular statement which some hospitals append to the annual report to their subscribers, and which, while it is expensive to print and troublesome to construct, hardly fulfils its poor purpose of making a show before the public.

I sincerely hope that the physicians and surgeons engaged in this important work in London will respond to Mr. Howlett's appeal, waiting for no patronage and admitting no interference.

Your obedient servant,

Wimpole-street, July, 1880.

OCTAVIUS STURGES.

In the Annual Report of the Stockwell Orphanage, the medical officer states that "consumption has never been introduced into the Jewish community." The statement is not borne out by many well-ascertained facts. There is no immunity from phthisis among the Jewish nation. We are not aware of any writings on the subject.

Dr. Whiteside Hime.—Although we are by no means disposed to exaggerate the importance of the Bill, we think that every effort made in the direction our correspondent suggests would be advisable.

W. A.—The practice was probably sold subject to our correspondent's undertaking, so that it would be a breach of good faith.

ADMINISTRATION OF NITROUS OXIDE GAS.

To the Editor of THE LANCET.

SIR,—With regard to the "new instrument for the better administration of nitrous oxide gas," as recommended by Mr. Donald Napier in your impression of June 26th, may I submit that I have for a very long time used the two cylinders in a form that may be more convenient to some of your readers. The cylinders are in tripod stands that close to the bottles when not in use, the tube connecting them being a Y-shaped india-rubber tube. The advantages to myself are: portability; disconnection; the being able to use a twenty-five gallon cylinder in place of a fifty; Clover's foot-key (much better to regulate than the hand-key); takes up less room; is light to carry, besides being firmer and lower to foot-key.

Brook-street, June 30th, 1880.

Yours very truly,

TOM BRID.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

At the Primary Examination for the diploma of Membership of the above College, which is now going on, there are nearly 200 candidates, to whom the following questions on Anatomy were submitted at the written examination on the 2nd instant, when they were required to answer only four out of the six questions:—

1. Describe the first dorsal vertebra and its articulations.
2. Describe the external oblique muscle of the abdomen and its aponeurosis. Give their attachments and relations.
3. Describe the male urethra.
4. Give the dissection necessary to expose the deep plantar arch, describing the parts seen in succession.
5. Give the course, relations, and distribution of the ulnar nerve below the elbow.
6. Name the arteries distributed to the brain. Give the course and anastomoses of each.

The following were the questions on Physiology:—

1. What are the proximate constituents of wheat flour; what changes do these constituents undergo in the conversion of flour into bread, and how is their digestibility affected by these changes?
2. Describe the action of the heart, and give the evidence that the blood circulates through the vessels.
3. How is the nervous system concerned in tranquil respiration? What are the phenomena presented by the nervous and vascular systems in death by asphyxia?
4. What varieties of cartilage are found in the adult, and in what situations? Describe the structure and uses of each variety.
5. Explain what is meant by the following terms:—Cell, tissue, organ, organism, organic and inorganic matter, proteid, peptone, ferment, carbo-hydrate, hydrocarbon. Give examples of each.
6. Give the structure of the epithelium and papillæ of the tongue. By what nerves is the tongue innervated, and what are their functions?

H. G. S.—Niemeyer's Medicine, Bryant's Surgery, Ringer's Therapeutics, Meadows' Midwifery, Guy's Medical Jurisprudence, and Wilson's Hygiene may be recommended.

Perplexed.—No.

"EXTRACTING TEETH AND PUTTING THEM BACK INTO THE JAW."

To the Editor of THE LANCET.

SIR,—I have been following the discussion, originated by you, on the extraction and replacement of teeth with much interested anticipation; but I must say that up to the present time the thing which has appeared to me the most remarkable has been the small amount of light thrown upon the subject by our dental brethren. It is needless to say that such a question can only be settled by the production of facts; but if settled in the affirmative, as I believe it will, one or two other inquiries of a like nature would suggest themselves as also worthy of solution. For instance, can the teeth pulled out of one person be replaced successfully by those pulled out of another? Also, can they be replaced by those of any other animal? I regret that I can supply you with no facts of my own; but many years ago I was consulted by a sailor of large and varied nautical experience, and he told me that on one of his voyages the men were attacked by scurvy, which was so severe that it caused all the teeth of one man to become loose, and, said he, "Would you believe it, Sir, he pulled a lot of his teeth out, scraped them, and put them back again, and they grew as firm and useful as ever." I should judge him to have been a veracious person.

Subsequently I questioned closely another old salt, and he declared most positively that he had known the same thing done in scurvy, and that it was by no means uncommon.

My assistant, Mr. George Billing, assures me that when he was with Dr. Segar, of Southport, he four times saw the doctor resort to this proceeding, and he remembers only one instance in which it was not successful.

I am fully aware that these somewhat apocryphal instances by no means come up to the standard of modern scientific evidence; but perhaps they may act as a stimulus to those who are in possession of better facts to forward them to you.

Yours obediently,

Blackpool, June 28th, 1880.

WM. HARDMAN.

To the Editor of THE LANCET.

SIR,—The following case may be of interest to those of your readers who are watching the correspondence appearing in your valuable journal on the above subject:—

On the 10th of June, 1875, I was called to E. P.—, a lad about fifteen years of age, who, half an hour before I saw him, had been kicked by a horse. Besides a severe cut over the left upper lip, extending to the cheek, I found the left upper canine tooth had been broken off, and the first bicuspid on the same side knocked entirely out of its socket. The latter tooth was found, and, after wiping, I put it back into its place, fixing it to the second bicuspid with a bit of silver suture wire. A fortnight later I removed the wire, and found the tooth quite firm. About a year after the accident I saw the boy for the last time; the tooth was as firm as ever. A day or two since I wrote to the boy's mother, and I have this morning received her reply, in which she states the tooth "has answered as well as if it had never been knocked out."

I am, Sir, yours truly,

Bridgwater, June 16th, 1880.

J. BAIN SINCOCK.

Fellow Med. Chir. Soc.—It has not often happened. In 1815, Mr. Henry Cline, President of the College of Surgeons, was at the same time President of the Medico-Chirurgical Society, and Sir James Paget did the double duty in 1875; and now Mr. Erichsen, F.R.S., who so worthily fills the chair at the Society, has just been elected President of the College.

F. M. T.—Write to the Secretary of the Local Government Board (Ireland).

STIMULANTS AT THE BRISTOL WORKHOUSE.

A CORRESPONDENT writes as follows:—

"The remarks of Lord Carnarvon in the House of Lords on the use of stimulants in workhouses—and which, like too many remarks in Parliament, were very indistinctly heard in the reporters' gallery—have called forth an investigation by the guardians of the Bristol Workhouse. Of seven workhouses brought into comparison, the Bristol Workhouse is one of the cheapest from which returns have been received. The cost per head is lowest in Bristol, being 3s. 3d. against 4s. 9d. at Nottingham. As to the cost of milk and the percentage of sick, Bristol was half way down in the same list, and second as to quantity of wines, spirits, and beer consumed. The Committee, whose report was unanimously adopted by the Board, recommended 'That all beer and other stimulants ordered for the paupers who act as nurses, or are employed in any unpleasant work, be supplied to them with their meals, and that the paupers be not permitted to take any part of their allowances out of the dining-room; also that the stimulants ordered for the sick paupers be administered by a paid responsible officer, unless directions to the contrary be given by the medical officer, and that once a quarter at least the medical officer do specially reconsider every case in which stimulants may be in course of administration.' The vindication of the Board is pretty complete. There is one element, however, in all these rivalries in economy in workhouses that should never be lost sight of—viz., the health and longevity of the paupers upon whom the experiments are made. It is possible to reduce even to mere water the diet; but if this is accompanied with diminished strength and lowered vitality, it is little creditable. There is much to be said for only the most careful administration of beer and stimulants to paupers under the responsibility of the medical man; but what is saved in this way should be spent in the general improvement of the pauper's diet, which is certainly not excessive."

HOT-AIR BATHS.

To the Editor of THE LANCET.

SIR,—In your impression of June 5th you refer to the subject of ventilating Turkish baths and the difficulty of obtaining pure air, more particularly, I apprehend, in the hot-air chambers. Now, I venture to state that it is quite practicable to ventilate Turkish baths so effectually that not only shall the impurity of the air be inappreciable in the slightest degree, but that the air shall be rendered absolutely pure.

Having given considerable attention to the subject of hot-air baths, and as architect of one of the best-appointed, and I may say one of the most favoured Turkish baths in the metropolis, I beg to be allowed to describe the system of ventilation adopted, more particularly in order that the public may know that there are Turkish baths in London which may be visited without the slightest possible chance of any danger such as you have referred to.

In all cases purified air should be taken into the bath as well as the impure air extracted therefrom. In the case of the Turkish baths at Camden-town, the air is brought to the stove and hot-air chambers from an external vertical shaft by means of a channel communicating with the heating stove, up which it rises and passes in a highly heated state through a grating in the floor above, to the "laconicum," or No. 3 hot room. It then distributes itself, after filling the "laconicum," to the adjoining chambers through the door openings, and by means of other channels it passes underneath the stove into the spaces under the marble benches, and enters the hot-air rooms through sliding gratings at a temperature of 100°. The impurities in the air which fall towards the floor are carried off by means of flues underneath the floor-tiles, all concentrating to a common upright shaft in an adjoining compartment to the smoke-shaft, and which is necessarily highly heated, and the exhausted air passes out through an extractor at the top of the smoke-shaft. Whatever may be left is carried off through specially constructed gas suspenders, together with the gas combustion, into channels in the floor above; these again concentrate, and are attached to another heated upright shaft. Besides the flues mentioned, there is a stained glass ceiling light at a height of twelve feet, openable, and through an outer light it communicates direct with the external air; but it has never yet been found necessary to open this light for the purpose of ventilation. Although a bather on an average of twice weekly since these baths were opened in 1873, I have never yet heard a complaint of impurity of the air; in fact, the air in consequence is seldom less than 140°, 180°, and 230° respectively, something above the customary temperature, yet without the slightest discomfort; indeed I have thoroughly enjoyed a quarter of an hour in the "laconicum" at 250°.

An ill-ventilated bath is self-detecting. It generally produces *ennui*; hence the frequent complaint of this feeling by bathers, even though there may be no unpleasant smell, but I have visited baths where the latter has been intolerable to an educated nose. I therefore consider your admonitions in this respect most salutary, although habitual bathers will soon find out and relinquish baths where their safety is not regarded. Your observations, too, with reference to the attendance is

warranted; for one regrets to have to confess that in establishments where this would be least likely to be expected, and where, doubtless, the proprietors pride themselves on the appellation of the Turkish baths, this is noticeable in a marked manner. The apathy and indifference to the comfort of bathers, with not half a shampoo, and so little water, and one's freedom and wants curtailed to the last degree, leave a lasting impression; but the faculty will, doubtless, take care to send their patients where they know proper attention will be paid both to their patients and to their instructions, and where the bath can be enjoyed with some freedom from restraint.

I would add, it is most desirable—imperative even, so far as healthiness is concerned—that Turkish baths should not be "adapted buildings" from some private house or shop, but should be built for the purpose, and constructed with proper materials, such as concrete and tiled floors, concrete and plastered ceilings, and brick walls. Timber floors and partitions in old buildings often emit unpleasant smells, especially when heated, and it is impossible to keep the rooms sweet. Any felting or curtains in the hot rooms should be frequently renewed, and all the chambers kept scrupulously clean. Bathers are most sensitive in these respects.

Yours obediently,

London, June 15th, 1880.

H. H. BRIDGMAN, A.R.I.B.A.

To the Editor of THE LANCET.

SIR,—In a short article with the above heading in your issue of June 5th, the writer says: "If the air of a Turkish bath is laden with germs of disease thrown off from the lungs of a fever or a consumptive patient, there are no currents to carry the particles away. It is a physical certainty that others breathing in the bath must inhale them. This is an evident source of peril, and suggests the wisdom of taking measures to insure the frequent changing of an atmosphere which may be thus easily polluted." When the Turkish bath was first introduced into this country, the hot rooms were heated mostly with smoke flues traversing under the floor, and there was no ventilation, certainly no constant change of air. There may be a few baths still so heated; but at the present time there is no difficulty in steadily maintaining the necessary high temperature in the hot-rooms, with a constant change of air equal to thirty cubic feet per minute for each bather, which is more than is insisted upon in the best hospital. Having been interested in the Turkish bath for many years, I have all along been impressed with the importance of thorough ventilation in the hot-rooms, and to that end have made numerous experiments, which have eventually resulted in the production of the convoluted stove, which, owing to its large radiating surface and small grate space, produces an immense volume of moderately warmed air, without the possibility of over-heating; and the air being drawn directly from the outside, the supply of fresh air is constant. Most of the baths in this country are heated by the apparatus named, and ventilated in the manner indicated. In towns or crowded places the air may be filtered in various ways before entering the heating chamber surrounding the apparatus. I may state briefly that by this mode of heating the superficial area of the outlets for vitiated air may be the same, within a fraction, as the flue by which the fresh warm air enters, and there being no valves used, an uninterrupted change of atmosphere is insured.

I am, Sir, yours &c.,

Manchester, June 16th, 1880.

JOSEPH CONSTANTINE.

SOCIÉTÉ FRANÇAISE D'HYGIÈNE.

"LE CONCOURS. — Hygiène et Éducation physique de la seconde enfance. La salle d'asile modèle, est prorogé au 1er janvier 1881 et modifié de la façon suivante: — Ire question: Hygiène de la seconde enfance jusqu'à l'âge scolaire, c'est-à-dire de 2 à 6 ans, embrassant tout ce qui concerne l'hygiène proprement dite, y compris le développement normal des organes des sens, mais sans toucher à la pédagogie infantile. 2e question: Hygiène et pédagogie des salles d'asile modèles. La partie hygiénique se rapportera exclusivement au milieu spécial de la salle d'asile. La partie pédagogique aura exclusivement pour objet le développement harmonique du corps et de l'intelligence. Dispositions et formalités générales: Les deux questions précédentes constituent deux concours bien distincts, et récompensés chacun par une médaille d'or, une médaille d'argent et trois médailles de bronze. Les mémoires écrits en Français, Anglais, Italien ou Allemand devront être adressés, sous la forme académique, au siège de la Société française d'hygiène, rue du Dragon, numéro 30, avant le 1er janvier 1881. Les auteurs qui se seront fait connaître, soit directement, soit indirectement, seront exclus du Concours. L'étendue des mémoires ne devra pas dépasser 30 pages d'impression in-12. Les mémoires couronnés appartiendront à la Société qui pourra les imprimer, en totalité ou en partie; elle s'engage toutefois à inscrire le nom des Lauréats en tête de l'opuscule qui sera répandu autant que possible."

UNQUALIFIED MEDICAL OFFICERS TO PUBLIC INSTITUTIONS.

To the Editor of THE LANCET.

SIR,—I notice in the reply to "J. D.," in your issue of the 26th ult., that you state the following: "Every public hospital is bound to employ qualified officers for its medical service." Would you or any of your readers kindly inform me of what material the ligature is composed, as I am ignorant of any stronger tie than that of professional opinion? I regret to say that it is a practice by no means uncommon to appoint unqualified men as house-surgeons to provincial hospitals, to the detriment of the officers themselves, their hospitals and patients, and the medical profession at large.

I am, Sir, faithfully yours,

Mare-street, Hackney, July, 1880.

SAMUEL WILSON.

"BONE-SETTING."

To the Editor of THE LANCET.

SIR,—In your impression of May 8th Dr. Monckton calls the attention of the profession to the treatment of stiff joints. The following cases, which have recently occurred in my own practice, I deem worthy of bringing under your notice:—

A patient aged fifty had a subglenoid dislocation of the humerus. I reduced it easily, bandaged the arm to the side, and enjoined rest. Three weeks after the lesion occurred he was unable to abduct his arm in the slightest degree, and, as I naturally felt very anxious about the case, I took him to London, and had the advice of a surgeon of eminence, who at once pronounced the case to be one of "muscular adhesion," placed my patient under gas, and forcibly put the joint through its various motions, assuring both myself and my patient that free motion of the shoulder-joint would immediately ensue. It has not done so, however; and now, after six weeks' interval, the latter is unable to raise his arm, or even to write; he has a hard lump between the long and short heads of the biceps, and also between the insertion of that muscle and the brachialis anticus.

A school-boy fell with his arm elevated, and several boys fell upon him, causing dislocation (downwards and backwards) of the humerus. There was great displacement of the parts, but I effected reduction easily and satisfactorily. I afterwards put the arm in a sling, and told the boy to raise the limb right up every other hour during the day. He did so, and in a week's time the use of his arm had returned almost as well as ever, and there was comparative absence of pain.

A woman aged thirty, whose sister and two brothers all suffer from flexed knee-joints, the result of arthritic disease, sent for me complaining of severe pains in the knee-joints. On examination, I found her suffering from synovitis with slight effusion. In three days both her knees were flexed, in spite of every effort made to the contrary, and she was unable to extend them. The deformity of the other members of her family already mentioned being prominently under my notice, I determined that at all risks she should not suffer as they had done. I therefore placed her well under chloroform, and forcibly extended both legs, bandaged them together, and fixed a five-pound weight working upon two pulleys upon them, which made direct traction in the long axis of her body, at the same time treating the synovitis *secundum artem*. In a fortnight she could walk without pain or any other synovitic symptom.

I am led to believe that the first case I write of was not one of a muscular but of a neurotic nature; that the second case was treated contrary to the treatment usually taught at our medical schools; and that the plan adopted in the third case is similar to that for which "bone-setters," and until recently "bone-setters" alone, gain such credit.

I remain, Sir, yours truly,

Poole, June, 1880.

Lectures ON THE

PHYSICAL EXAMINATION OF THE MOUTH AND THROAT.

*Delivered to the Junior Class of Clinical Medicine,
University College,*

By G. V. POORE, M.D., F.R.C.P.,

PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE; LATE
ASSISTANT PROFESSOR OF CLINICAL MEDICINE; ASSISTANT
PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE
THROAT DEPARTMENT OF THE HOSPITAL, ETC.

LECTURE IV.

THE LARYNX AND THE USE OF THE LARYNGOSCOPE.

GENTLEMEN,—We have now discussed all those objective phenomena of the mouth and fauces which are appreciable to our unaided senses. It is always my custom to advise you to trust as much as possible to your unaided senses, and always to make a point of learning as much as possible about a patient without having recourse to those various "scopes" which students are very prone to regard not merely as valuable accessory aids to our senses, but as absolutely indispensable for the acquisition of any knowledge at all.

You will find that it is quite possible to learn a great deal about the larynx without looking at it at all, and that alterations in voice, respiration, and swallowing, combined with palpation, may teach us a great deal. For convenience sake, however, we will depart from our rule of considering all simple means of investigation before the instrumental means, and proceed at once to speak of the laryngoscope.

The laryngoscope, an instrument for obtaining a view of the larynx, is a modern invention. Mirrors for illuminating the throat had been used in an unmethodical manner for many years, when Signor Garcia, a singing master, presented a paper to the Royal Society in 1854, on the Physiology of the Vocal Cords, based upon an examination of his own vocal apparatus by means of a laryngoscope. In 1857, Türk of Vienna, and Czermak of Pesth—especially the latter,—succeeded in bringing the laryngoscope to the general notice of the profession.

I shall not detain you many minutes with directions for using the instruments; that is a practical matter, and a very little practice will make you a proficient in the art. To use the laryngoscope aright is a far easier thing to learn than to use the stethoscope or ophthalmoscope. The laryngoscope consists of a mirror worn by the observer, by means of which a strong light is reflected to the back of the pharynx, and there again reflected downwards to the larynx by means of a second and a smaller mirror, upon which an image of the larynx becomes visible. A few words may be added in amplification of this.

1. As to the source of light. The best of all is the sun; and whenever you can get the chance of doing so, place your patient in a chair, with his back to a window, and reflect the rays of the sun directly into his throat. Failing the sun, an Argand gas-burner, or, better still, a mineral-oil lamp, with either a flat or a circular flame (I prefer the latter), form excellent sources of light for this purpose; and as the one or the other exists in every house, you should accustom yourselves to use them. An ordinary gas-flame, or even a candle, will answer the purpose. No lenses or condensers are necessary, and you may have observed that I never use either the one or the other. I strongly advise you not to get in the habit of using cumbrous and expensive apparatus, which you may not be able to obtain when most needed, and which really hinder that training of the senses, after which we should all strive. Some persons prefer a direct illumination of the pharynx, but you will find it generally most convenient to place your source of light a little behind and to one side of the patient, and then to reflect the light into the throat, exactly as a schoolboy uses a bit of looking-glass for the purpose of throwing a light into someone's face.

2. The reflector may be mounted on an india-rubber band or a spectacle frame, and it must be perforated in the centre,
No. 2968.

and be movable in all directions upon a ball-and-socket joint. The reflector is best worn over one eye, the operator using the central perforation for the purposes of vision.

3. The laryngeal mirrors vary in size from a sixpence to a florin, and are mounted on slender handles. The handle and the mirror should form an angle of about 120°, and the handle should be sufficiently pliable to admit of this angle being varied at the pleasure of the observer.

A few words as to the method of using the instrument. Let the patient sit facing you, with the knees together, on an ordinary chair, and with the illuminating lamp upon a table, or otherwise suitably supported, just behind and to one side of him, the flame being about on a level with his ear. Sit immediately opposite the patient, and ask him to sit quite upright, with the head a little thrown back. Tell him to open the mouth, and then adjust the reflector, so that the light is thrown upon the pharyngeal wall, the uvula, and the arches of the palate. Ask him to protrude the tongue fully, and then *gently* and neatly wrapping the end of it in a smooth fold of a soft small napkin, take the tip *gently* between the thumb and forefinger of the left hand, and retain the tongue in its protruded position with the least possible amount of pressure, and absolutely without anything like forcible traction. If the second finger of the left hand be passed beneath the patient's chin, any unintentional wandering of the hand is prevented.

Be sure and use all gentleness in these manipulations. Anything like force leads to struggling on the part of the patient's tongue and to spasms of the pharynx, and is fatal to your object. Next, take a laryngeal mirror of suitable size and hold it lightly, like a pen, in the right hand. Many students hold the mirror too tightly, and with the end of the handle touching the palm of the hand. Held in this position it is impossible to alter the direction of the mirror without moving the entire hand and wrist. If it be held like a pen, the mirror can be moved freely in all directions simply by the movement of the tips of the thumb and first two fingers.

The mirror must be warmed before being introduced into the mouth to prevent the condensation of moisture upon its surface. This end may be attained also by smearing the surface of the mirror with glycerine and water, but heating is a better plan, as, being cleaner and simpler, and likely to lessen instead of increase the risk of any carriage of infecting particles from one patient to another. In passing the mirror to the back of the mouth follow the natural curves of the mouth, and pass the mirror over the dorsum of the tongue without touching it. If skilfully passed the mirror should touch nothing until the edge of the soft palate is reached, when the uvula should be gently pushed upwards upon the back of the mirror. Then if the patient be asked to take a deep breath a complete image of the larynx is obtained.

In a favourable case there is really no difficulty whatever in doing what I have described. You will find, however, many patients who are very intolerant of any manipulation of the mouth or throat, and the mere *idea* of the examination is enough to make them double up their tongues, contract the pharynx, retch, and even vomit. In such cases you must be doubly careful not to touch the mouth, and particularly to avoid irritating the posterior pharyngeal wall. It is a good plan to keep such patients occupied and to make them inspire and expire deeply and frequently during the whole period of examination, and to utter sounds, such as "Ah" or "Eh." When asked to "take a deep breath" many of the irritable patients do nothing of the kind, but merely contract the pharynx and hold the breath. It is often necessary to teach them what is wanted to be done. The irritability of the throat may be lessened by sucking ice. The bromide of potassium administered for a few days in doses of ten or fifteen grains will diminish the irritability in a very remarkable manner. Great irritability of the throat is natural to some people, but in the great majority it is indicative of gastric hyperæmia, and is especially observable in people who indulge in alcoholic stimulants. In such cases the combination of Epsom salts with the bromide is very useful.

But now let us suppose that the laryngeal mirror is successfully placed *in situ*. What do you see reflected in the mirror?

At the top of the mirror is seen the epiglottis; at the bottom are seen the two prominences caused by the tips of the arytenoid cartilages, or rather by the cartilages of Santorini which surmount them. Between the edges of the epiglottis and the cartilages of Santorini are two folds of mucous mem-

brane called the aryteno-epiglottic folds, and during deep inspiration a fold of mucous membrane is observed stretching between the arytenoid cartilages and forming the posterior wall of the larynx. The parts I have named form a frame, as it were, and in it are seen the pearly white vocal cords, stretching like an inverted Λ from the epiglottis (apparently), where is the apex of the triangle, to the arytenoid cartilages, where is the base. Between the vocal cords and below them may be seen a transverse striation caused by the rings on the anterior wall of the trachea, and in very favourable cases a glimpse may be caught of the division of the trachea into right and left bronchus. Between the aryteno-epiglottic fold and the vocal cord on either side is seen the red mucous surface of the ventricular band or false vocal cord.

These appearances differ at different times. During deep inspiration the arytenoid cartilages are separated by a third of an inch or more, the inter-arytenoid membrane is well seen, and the triangle formed by the separated vocal cords is very evident. During phonation, however, when the patient is made to say "Ah," the arytenoid cartilages and the vocal cords are brought close together, and the rima glottidis is almost completely shut.

It may be well to mention that healthy larynges differ considerably in appearance, and the shape of the epiglottis is as varied as is the shape of the ear or nose in different individuals. It may be well to mention also that in a certain very small percentage of cases the epiglottis is so pendulous as completely to obscure the larynx.

I must remind you that the image which you see in the laryngeal mirror is a reflected one; and just as in an ordinary looking-glass the right hand of the spectator becomes the apparent left of the image, so the parts of the image of the larynx which are to the observer's right hand are in reality those which are on the left side of the patient's larynx. Remember also that the upper part of the image, the epiglottis and the apex of the triangle formed by the vocal cords—the parts which seem furthest off—are those which form the anterior wall of the larynx, while the bottom part of the image is formed by the posterior laryngeal wall. It is very important to remember this when you come to make applications to the larynx.

I may mention that the laryngeal mirror is useful as enabling one to get a good view not only of the larynx, but of the base of the tongue—the papillæ circumvallatæ and the parts beyond, and the glosso-epiglottic fossa. It enables us also better to explore the pharynx and the arches of the teeth.

The diseased appearances of the larynx are in kind similar to those which are seen in the pharynx.

Hyperemia is very easily produced by any irritant. In the rapidity with which hyperemia may be brought about the larynx resembles the conjunctiva, and a particle of food or dust will cause a general distension of the vessels, and a swelling of the mucous membrane almost instantaneously. If the irritant be a powerful one, such as boiling water, the hyperemia may cause oedema, and the swelling may be so great as to produce suffocation and death in a very short time.

Hyperemia is not only brought about by direct irritation of solid particles, but by over-use of the larynx in talking or incessant coughing, exposure to cold, and atmospheres laden with solid particles either in workshops or in London fogs, by the too frequent use of strong drinks, and by gastric irritation however induced. It is seen also in certain constitutional states, such as syphilis, gout, and consumption. The hyperemia may affect any part. When it affects the vocal cords they lose their pearly-white shining appearance, and look very often as if a very thin layer of treacle were smeared over them, or possibly tiny vessels may be actually visible upon their white surface.

Anæmia of the larynx is present as a part of general anæmia. Occasionally the anæmia of the larynx is greater than that of other parts, and I have seen cases where the pallor of the larynx has been very great, while no very obvious signs of anæmia existed elsewhere. Such anæmia of the larynx is generally accompanied by some impairment of function, and is said to be a precursor of laryngeal phthisis. I can call to mind four cases, at least, in which the anæmia of the larynx was a very marked feature. One was in a girl, who had signs of locomotor ataxia combined with paralysis of the palate; another was in a medical student with a sluggish follicular ulceration of the larynx, and in whose family there was a well-marked tendency to phthisis;

a third was in a boy who had been seized with aphonia during convalescence from measles, and a fourth was in another boy, who was recovering from an attack of whooping-cough.

In *inflammation of the larynx* there are the usual objective signs of inflammation—viz., redness and swelling. In acute laryngitis the swelling may be enormous. The epiglottis may be two or three times its natural size, and the aryteno-epiglottic folds may be distended to such an extent as to obscure the false cords and the glottic chink. The parts may be dry on the surface, and of a fiery redness, or, as is more often the case, they are bathed in mucus. In such a condition the patient is in imminent danger of his life, and presents all the symptoms of one who is in fear of immediate suffocation. Between these extreme appearances of inflammation and a mere thickening and slight discoloration of the cords there is, of course, every degree of redness and of swelling. Acute laryngitis is liable to occur from exposure to cold, or from direct injury to the part. In children it is known as catarrhal croup, and in adults it is liable to come on after the acute specifics, or during an attack of erysipelas. If there be any disease of the kidneys, the oedema in these cases is apt to be alarmingly great.

As a result of acute laryngitis abscesses may form in the submucous tissue, and then, when the general redness and swelling is subsiding, a smooth globular elastic swelling is left at one spot. A great cause of laryngeal abscess is necrosis of the laryngeal cartilages which is liable to occur as a result of laryngitis, and especially after typhus and other exhausting fevers, and in tubercular and syphilitic disease. The arytenoid cartilages are most often affected, and then we find a globular elastic swelling at the posterior part of one or other of the aryteno-epiglottic folds. Next to the arytenoids the cricoid is most prone to suffer, and the resulting abscess may either form a projection into the larynx beneath the vocal cords, or it may project backwards into the œsophagus, and in doing so interfere with swallowing and with the function of the muscles which cover the posterior surface of the cricoid. The thyroid is occasionally, but not often, the seat of necrosis and resulting abscess.

Chronic laryngitis presents symptoms the same in kind as are seen in acute laryngitis, but usually more localised; and we find that the epiglottis, the aryteno-epiglottic folds, the false cords, or the true cords themselves, are mainly affected.

We may find that the only sign of laryngitis is a very slight thickening and redness of the vocal cords just at the point where the elastic cord joins the processus vocalis of the arytenoid cartilage, and this is a point to which the practical man will specially direct his attention. During phonation, when the arytenoid cartilages rotate inwards, the tips of the processus vocales impinge against each other, and this constantly-recurring shock is enough to determine the inflammatory action to this spot.

There are three great constitutional causes which determine the chronicity of a laryngitis or laryngeal catarrh. These are syphilis, phthisis, and alcoholism. Two of these causes are often combined, and occasionally all three. Now it is important to consider whether, from the appearance of the larynx alone, one can tell which of these causes is present. There may be simple diffused redness of the larynx, and then it is quite impossible to say to what cause it is due, and your opinion will be formed entirely by the concomitant symptoms.

Syphilis will cause swelling of the mucous membrane, accompanied by mucous patches and superficial ulceration exactly similar to the appearances which I have described as occurring in the pharynx, and seeing these the practised eye will recognise their cause at once. Gummatæ may grow in the mucous membrane here, and that uniform syphilitic infiltration which we have noticed as occurring in the tongue and pharynx may also take place in the larynx, causing great swelling of the epiglottis, false cords, and the aryteno-epiglottic folds, and occasionally swelling also of the parts beneath the true cords. As a general rule, it may be said that in the syphilitic conditions the mucous membrane is not of a very deep tint, and the parts look harder. I am in the habit of saying that, when the appearance of the swollen mucous membrane reminds me of a "white-heart" cherry, I suspect syphilis, but when I am reminded of a ripe strawberry I suspect some other cause (often phthisis) for the catarrhal condition. The infiltration of syphilis may produce complete occlusion of the glottis. Sloughing and contraction of the parts may occur, and so much distortion as to render them scarcely recognisable.

The epiglottis may be completely destroyed, or may appear notched and crumpled, and unequally thickened.

With regard to "laryngeal phthisis," as it has been called, Von Ziemssen says, "Neither the catarrh nor the ulceration of phthisical subjects presents any characteristic signs by which it could be recognised as such." This is perfectly true, and my experience enables me to endorse this assertion. It may be said, however, that in laryngeal catarrh of phthisical origin the mucous membrane looks red and soft, like an over-ripe strawberry, and often the glandules of the part, being swollen, increase the resemblance to the texture of the strawberry. There are especially two parts which are very liable to be attacked in phthisis—viz., the epiglottis and the posterior parts of the aryteno-epiglottic folds. When we see the epiglottis fiery red, puffy and granular, and bathed in mucus; and when we see the so-called pyriform swelling over the arytenoid cartilages, with the big ends of the pear-shaped masses touching behind and the thin ends stretching towards the sides of the epiglottis; when these pear-shaped masses look red and granular, and when we see mucus welling up between them, we have very strong grounds for suspecting phthisis as a cause of the condition. Many of you, however, may have seen a patient whose condition was to the eye most suggestive of phthisis, but whose recovery was only brought about by active mercurialisation, and the occurrence of such cases should make one careful not to jump to conclusions.

Alcoholic laryngitis has nothing very characteristic about it, although I fancy that the epiglottis is the part most generally attacked.

In all cases of chronic laryngeal catarrh your conclusions as to the cause must be largely drawn from the concomitant symptoms: The laryngeal appearances may or may not be highly suggestive; but an alcoholic smell in the breath, combined with a bloated countenance; or the characteristic anæmic condition seen in syphilis combined with pharyngeal syphilis; or emaciation, rapid breathing, a hectic flush, and a flattened chest, will generally serve to confirm or correct the opinion which an inspection of the larynx has led you to take.

Ulceration of the larynx is commonly present in two conditions—viz., syphilis and phthisis. In both it may be very extensive, and may occur at any part—on the epiglottis, the false or true cords, the aryteno-epiglottic folds, or the inter-arytenoid space. The ulceration is very similar in both conditions. In phthisis the seat of the ulceration is very apt to be the tip of the processus vocalis, or the part of the laryngeal wall between the arytenoid cartilages, or the surface of the swollen and reddened mucous membrane covering the arytenoid cartilages. In laryngeal phthisis the swollen and ulcerated condition of the posterior part of the aryteno-epiglottic folds often occasions very great difficulty in swallowing.

Adventitious Growths.—In croup and diphtheria a false membrane grows upon the laryngeal mucous membrane similar to that which is seen on the pharyngeal. "Thrush" may affect this part, and we may find patches of oidium albicans. Occasionally cancer, usually of the epithelial type, attacks the larynx, and when it does so it is almost always by spreading from the œsophagus. The appearances are the same as those caused by epithelioma elsewhere—thickening and infiltration of the part, with ulceration and a foul unhealthy surface. Here there is no attempt, as in syphilis, to cicatrization and repair, and the act of destruction is continuous. In the late stages diagnosis is easy, but in the early stages it is difficult. The concomitant symptoms and the microscopic appearance of expectorated matter are great aids in forming a diagnosis.

New growths of a simple character in the larynx, forming tumours upon the laryngeal mucous membrane, are not uncommon. In all cases of prolonged laryngeal catarrh the mucous membrane is apt to become thickened and nodular, and may project into the laryngeal cavity. Such mucous projections, although they may prove tempting objects of attack to aspirants for fame, are in no sense new growths, and do not often call for any surgical interference. We have recently seen in the Throat Department a good example of a simple laryngeal tumour—viz., a globular round-celled sarcoma, as big as a hazel-nut, growing by a broad base from the anterior part of the left ventricular band or false cord. The most common among these formations are papillomata, or warts and fibromata or polypi. These tumours seem to have their origin in hyperæmia of the mucous membrane, however brought about. Occasion-

ally there is a syphilitic history. They may grow from any part of the laryngeal mucous membrane, true or false cords, the aryteno-epiglottic folds, or the inter-arytenoid space, and the laryngoscope enables us to see their exact position and their naked eye appearance, whether warty or polypoid. The diagnosis of these conditions is impossible without the aid of the laryngoscope.

PART OF A Clinical Lecture ON THE

RADICAL CURE OF VARICOCELE BY THE GALVANIC ÉCRASEUR.

Delivered at the Westminster Hospital on July 3rd, 1880,

By A. PEARCE GOULD, M.S., F.R.C.S.,

ASSISTANT-SURGEON TO THE HOSPITAL, AND LECTURER ON ANATOMY
TO THE MEDICAL SCHOOL.

GENTLEMEN,—Although there are very many cases of varicocele in which no treatment, or only palliative measures, are required, you will meet with others in which it will be your duty to undertake the permanent or radical cure of the varix. These cases are as follow:—1. Where the testicle is atrophying. 2. Where the varicocele is double, especially if an examination of the semen shows an absence of spermatozoa, or the patient, being married, is sterile. 3. Where the opposite testicle is lost or useless from tumour, orchitis, epididymitis, or injury. 4. Where the varix is large and increasing, in spite of palliative treatment. 5. Where the varix causes much pain, or interferes with proper exercise and necessary work. 6. Where it is the occasion of marked mental depression. 7. Where the varicocele prevents acceptance for either of the Government services.

There are many plans for securing the radical cure of varicocele, including castration, excision of the veins, the actual cautery, forcipressure, and ligature. The ligature is the method most commonly adopted, and has been variously modified by Ricord, Vidal, Erichsen, Wood, and H. Lee. (These methods of treatment were then described.)

Of the efficacy of these treatments there can be no doubt, but unfortunately they have two drawbacks—the pain attending them, and a certain amount of danger. For a long time surgeons avoided as far as possible any interference with veins, and although veins are now ligatured almost as freely as arteries, there is no doubt that diffuse thrombosis, embolism, and septic poisoning are more liable to follow injuries of veins than of arteries. This being so, it is plainly the surgeon's duty to avoid in every possible way any irritation or disturbance of an injured vein, and it is because this principle is not sufficiently carried out that the usual modes of treating varicocele have been attended with serious and even disastrous results. The daily twist of Vidal's pin, and constant traction of Wood's spring, are not only painful, but opposed to the great principle that demands perfect rest to all inflamed and injured tissues, and veins in particular, while, in Lee's operation, the presence of two harelip-pins transfixing the scrotum is apt to set up œdema and inflammation, and their removal is not without risk of embolism. That these are no imaginary fears is evident from the published results of these and analogous treatments. Gant says that the results of the operations are "variable," and include diffuse inflammation and sloughing of the scrotum, suppurations of the testicle, phlebitis, pyæmia, and death; Erichsen records two deaths from the twisted suture; Gross had one death after ligature; Sir E. Home had one nearly fatal case; Escallier mentions two fatal cases of phlebitis, and Curling speaks of three cases of serious results, two of which were fatal. Some years ago the censor of one of the chief London hospitals died from pyæmia after Lee's operation. This list by no means includes all the accidents of these treatments—it makes no mention of the pain suffered, or of the inflammatory œdema and suppurations of the scrotum.

It was with the hope of avoiding these complications that I was led, now more than two years ago, to try the plan of subcutaneous division of the veins by means of a platinum wire heated to a red heat by electricity. The procedure is, as you have seen, very simple. First, feel for the vas deferens, and grasp the veins in front of it, and nip in the scrotum with the left thumb and forefinger; transfix the scrotum at this spot between the duct and the veins with a narrow bistoury, and pass a needle armed with a platinum wire in the track of the knife; then return the needle through the same apertures, but this time in front of the veins between them and the skin. Of course, if the vas happen to be in front of the veins, as was the case in that of W. C—, shown to-day, you modify the procedure a little. In this way you have the veins in a loop of the wire. It is better to make a puncture with a knife rather than merely to transfix with the needle, for the veins are looped up cleaner, there is not the same liability to include a portion of the skin in the noose as in the latter plan. Then attach the ends of the wire to the *écraseur*, and connect with the battery, using sufficient cells to cause a faint hissing noise; one cell of Grove's battery, or at most two, is sufficient. This step must be done deliberately; I have taken as long as five or six minutes over it. To protect the skin from burning, let some cold water trickle over it while the wire is burning its way through the veins. The after-treatment consists in perfect rest in bed for a few days, with the scrotum supported on a broad strip of strapping fixed across the front of the thighs. I have three times operated without anaesthesia, but the pain may be severe, and I prefer to have the patient under the influence of ether. After recovery from the anaesthesia there is an entire absence of pain, and this perfect freedom from spontaneous pain continues uninterrupted throughout the convalescence. A few hours after the operation the knobby feel of the varix is replaced by a soft even swelling, which lessens and hardens, and at the end of forty-eight hours is usually to be felt as a hard lump, about the size of a big marble. This is tender on pressure. By the end of a week it has lost its tenderness, and has shrunk to three-quarters its original size. The veins below can still be felt full, but not compressible, the blood in them has by that time coagulated, and they become smaller and firmer, until ultimately a small pea-like induration in front of the vas is all that is left, and even this may disappear, and no trace of the varix or operation be left, as in W. S—.

I have employed this method eight times, each time the varix has been cured, the symptoms complained of relieved, and no mischief to the testicle has followed. These eight cases have shown me that there are three things to be carefully avoided. The first is hurry in the section of the veins; twice a few drops of blood have followed the escape of the wire, but only so little as to require nothing more than lint or cotton-wool to be placed over the wound; in neither instance was there any hæmatocele. The second is to operate well above the tunica vaginalis; in one of my cases acute hydrocele was lighted up, it quickly subsided under belladonna fomentations. The third is burning of the skin, leading to a small slough; although there is nothing of serious moment in this slough, it is of course best to avoid it, and if the skin is incised and kept cold and the loop of wire not brought too small it can generally be saved.

I can recommend you to practise this operation, first, because of its entire painlessness after the few moments of its actual performance, and, secondly, because it fulfils the physiological indications better than any other I know of. My cases at present are too few to prove by statistics that it is less dangerous to life than those operations I have mentioned, but they are sufficient to show that the operation is simple, effectual, and introduces no new danger, while it is obviously free from the sources of irritation common to other methods.

The section of the veins is completed at once; there is no foreign body liable to set up inflammation left in contact with the healing veins, which are allowed to remain at perfect rest, while their seared ends are becoming permanently closed. As you are aware, the closure of an open vessel by the hot wire or iron is usually considered a particularly safe plan. There is also no interference with the skin of the scrotum, as in Lee's operation; no compression of the scrotal vessels, no oedema.

The only other method that I should at all recommend to you is the use of the catgut ligature applied to the veins subcutaneously. I have had no experience in it, but it has been done with success. I think the heated wire is

preferable, because the catgut ligature is rather uncertain in its action; it may soften very rapidly and then fail to occlude the vessels, or it may not soften at all and cut its way through the veins like an ordinary hempen or silk thread, or remain and subsequently light up inflammation. These accidents are only occasional, but we should none the less be on our guard against them, and give the preference to a plan of treatment which is free from them. In none of my eight cases has any slough separated from the veins; the eschar formed has been absorbed by the living tissues. I show you to-day four cases at varying periods after the operation illustrating their progress.

1. W. J—, aged seventeen, a large left varicocele, which he had noticed for "several years," left testicle smaller than right, complained of dragging pains in scrotum and up to left loin. Operation June 21st, 1879; left hospital June 28th. A firm induration the size of a marble felt; not tender; veins below plugged.

2. F. L—, aged twenty-four, single, injured left testicle five years ago; first noticed varicocele three years ago, after an attack of clap, since then the pain and swelling had steadily increased in spite of wearing a suspender. No constipation; external piles for two years. Operation May 28th; left hospital June 8th. The induration is very hard, the size of a horse bean; veins below are firm and shrinking.

3. W. C—, aged thirty, single, very large left varicocele, noticed suddenly in June, 1879, while bathing. Pain in scrotum and groin had increased of late; testicle smaller than right. Operation May 1st; left hospital May 7th; delayed on account of a slough of skin. Induration now small; veins below cannot be felt; testicle has regained its former size and is a little larger than right.

4. W. S—, twenty-one, a small varicocele noticed some years; scrotum not lax; considerable pain; frequent seminal emissions and mental depression. Operation Sept. 29th; left hospital Oct. 9th. No trace of dilated veins or of the seat of the operation to be felt. All symptoms relieved.

SOME STATISTICS OF FATAL CHOREA.

By OCTAVIUS STURGES, M.D.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

THE pathology of chorea needs to be discussed upon a wider basis than that which is offered by morbid anatomy. Nevertheless, no survey of the disorder can be complete which fails to take into account evidence of this sort. The review of a sufficient number of examples of fatal chorea, apart from any direct discovery of morbid change, cannot fail to be of service in exhibiting the age and sex and temperament most liable to succumb to such attacks. We are thus assisted in separating from one another a highly dangerous form of convulsion, and that far commoner motor disorder which, whether violent or not, has little or nothing of danger about it, and probably recovers best without active medical interference.

Yet, with this obvious service to be got from the study of fatal chorea, the event of death is so rare that no single observer from his own experience can do more than contribute a very small share of the material necessary for the purpose of drawing any general conclusions. Thus, Dr. Hughes, in so large a hospital as Guy's, was able to collect from all the records by various hands which had been preserved during more than thirty years, only eleven fatal cases. Dr. Dickinson, from a similar record at St. George's, extending over thirty-three years, collected sixteen such cases, while the large field of observation offered by the Hospital for Sick Children during fifteen years furnishes but six. These examples, it must be understood, include those dying with chorea as well as those dying of it. Although it is not always easy to distinguish between these two classes, it is certain, as will presently appear, that the cases of death attributable directly to chorea fall very far short of the numbers just given. It must be added that many of the earlier records are very defective, that there is no uniform plan of tabulation, and that with different observers different points of interest have received mention.

On the whole it may be said that if all the recorded accounts of fatal chorea in this country which are fairly complete and readily accessible were put together the total number would not be large, and that in a considerable proportion of these the immediate cause of death and the choreic disorder would be found in very remote and uncertain connexion.

Such being the facts of the case, I have thought it of interest to bring together eighty cases of death in connexion with chorea, or at least with convulsions resembling and called chorea. They are made up as follows:—(a) Three cases (quoted by Dr. Bright), *Med. Clin. Trans.*, 1839; (b) eleven cases (Dr. Hughes), *Guy's Hospital Reports*, 1846 (first series); (c) seven cases (from same source), 1855 (second series); (d) thirty-four cases (Dr. Tuckwell), *Bartholomew's Hospital Reports*, vol. v.; (e) twenty-two cases (Dr. Dickinson), *Med. Clin. Trans.*, vol. lix.; (f) three cases (Dr. Peacock), *St. Thomas's Hospital Reports*, vol. viii.

With these references and the frequent mention I shall have to make of each of these eminent authors no one can quote against me on their behalf the line that Virgil wrote on the palace gate. The present object is to bring together under one point of view a body of evidence derived from many sources without admixture of extraneous matter. Of the conclusions to be drawn from such evidence the reader will judge for himself.

The points I propose to examine concern the age and sex and common exciting cause of fatal chorea, together with its most obvious morbid associations. It will be seen immediately that only a proportion of the eighty cases are given in such detail as to be dealt with in all these respects. Thus Dr. Tuckwell's account is no more than a short summary occupying one paragraph of his paper just quoted. Dr. Hughes's first series is described by himself as "very meagre and imperfect;" Dr. Bright's three cases, although so often quoted, are not altogether in point; in one there was trismus and tetanic spasm, and in a second paroxysmal attacks described as hysteric. In the several enumerations now to be made, therefore, while eighty will be the extreme number dealt with, smaller numbers will have to serve in regard to particular points where the information is defective. With such deduction the cases available in all respects will not exceed thirty, but thirty in the circumstances of this disorder is a large number, it is the gleanings of a very wide field, the sum of fatality out of many thousand examples of chorea extending over a long period of years.

Taking in the first instance the gross number eighty as representing so many individuals dying in connexion with chorea, the most striking point of all to those who are in the habit of regarding chorea as a child's affection is the large proportion of adults and the small proportion of children. Of the eighty, forty-eight are over thirteen years of age, and the ages of two are not stated. Excluding Dr. Tuckwell's numbers, where further particulars are not given, we have in forty-six fatal cases twenty-seven who are over thirteen and nineteen who are under that age. Of the twenty-seven over thirteen, as many as twenty-three may be said to have died of chorea. Of the nineteen children, ten at the utmost died of it, the youngest of these being a girl of seven (No. 19 in Dr. Dickinson's table, *loc. cit.*). Or, again, excluding Dr. Hughes's first (and defective) series, we should have, out of a total of thirty-five, twenty fatal cases over the age of thirteen, of whom sixteen died apparently of chorea; and fifteen under thirteen, of whom only seven died apparently of chorea. We thus establish the fact, making large allowance for error (which from the nature of the material cannot be wholly excluded), that the mortality of children directly from chorea is exceedingly small, and that seven is the youngest age at which it is known as a fatal disease in a very extensive review. We find also, as we should expect in view of the comparative commonness of chorea in children, that the proportion dying *with* chorea but not *of* it is greater with them than with adults.

But next in regard to *sex*. In forty-six fatal cases (again excluding Dr. Tuckwell's) thirty-four are females and twelve males. Of the thirty-four females eight only were children, the youngest (mentioned above) seven years old, and one described only as "a child." As many as twenty-six were young women, eleven of whom, there is good evidence to show, died of chorea. Of the twelve males nine were adults and only three young boys. These latter are made up as follows: One is in Dr. Hughes's first series (No. 6), one is in Dr. Dickinson's table (No. 14), and died of heart affection "without return of chorea," and one is a case of the late Dr. Fuller's (No. 9 in the same table) that died under my own

observation as then Medical Registrar at St. George's Hospital, after five months of almost persistent convulsion. These three boys were each eleven years old. It does not appear upon the evidence before us that chorea is ever fatal to males at an earlier age than this, nor have we more than one out of the three whose death is immediately attributable to this disorder.

The puberty age, then, is the age of fatal chorea. If we take forty-six as representing the total number of persons dying in this connexion, thirty-five would be at or a little above the age of puberty, and twenty-five of these young women.¹ We are thus led to associate fatal chorea with the disturbing incidents of a critical period of life. And the more so inasmuch as in those instances where exciting causes are actually discovered and recorded (but a small proportion, it must be remembered, of the whole number), there is frequent mention of some special excitement of those parts and organs which in the plan of nature are properly over-active at this particular time. Thus Dr. Hughes, in his second series of cases, finds the genital organs unusually excited in three of the four cases examined, while in Dr. Dickinson's table out of nine dying directly of chorea, and with causes assigned, there are three in whom these causes are distinctly sexual.

And not only does fatal chorea attach peculiarly to the emotional sex and the emotional time of life, there are but few instances of it out of the few fully detailed cases which constitute our entire material in this matter where mental excitement does not concur with the bodily over-movement. Such mental disturbance embraces all varieties, from the hysterical to the maniacal. Here again, therefore, a distinction appears between the fatal chorea of adolescence and the non-fatal chorea of childhood. The latter, even in its greatest violence, is commonly quite apart from emotion. The disorder acquires this mental admixture at the same time that it reaches what may be called its dangerous age. It will be perhaps better in this place to cite instances rather than to quote figures. The condition to which I am alluding is manifested by particular incidents. Thus in a case related by Dr. Hughes (first series, *loc. cit.*, p. 390) a man of twenty-five, with violent and ultimately fatal chorea, was "sensibly hurt and shed tears when the bystanders observed that he could restrain the movements if he pleased." In a second case, by the same author (second series, p. 250), that of a girl of eighteen, the symptoms "which were at first slight were suddenly aggravated by fright caused by a patient in the same ward, and she became almost maniacal." In a third instance (from the same series, p. 251), a girl of sixteen, where "there was unusual excitement of the generative organs," the symptoms at first "partook of the character of hysterics, the patient appeared strange in her movements, and fancied that others were laughing at her." In a fourth, a boy of sixteen, "supposed to be addicted to secret vice, his early movements excited the derision of his comrades. Their conduct depressed him much, and he went suddenly into a fit, after which violent and universal chorea supervened." In all three of Dr. Peacock's fatal cases mental excitement is a prominent feature. In one of the very few cases that are recorded of chorea fatal as early as ten (Dr. Dickinson, *loc. cit.*, p. 2), it is related of the child (and some will probably regard the relation as trivial) that a little friend of hers had lately died of chorea, she had watched and imitated the movements, and when she recognised them in her own person made sure that she should meet the same fate. If it be remembered from how small a number of examples these instances are taken, even these few quotations will be allowed to have weight in showing the common habit of fatal chorea. I think it may be said, indeed, not only of fatal chorea but of chorea that at any part of its course threatens to be fatal (a comparatively large number) that amongst the symptoms that give alarm nervous exaltation (so to speak) is generally one.

But while the emotional origin of chorea is thus apparent, as well as the direct influence of mental causes in determining its fatal issue, it is not to be doubted that fatal chorea arises in some instances in immediate connexion with acute rheumatism. The evidence upon this point now before us is to the following effect:—Out of thirty-two fatal cases dying *with* chorea, and reported with sufficient fulness to be available (*viz.*, seven of Dr. Hughes', second series, twenty-two of Dr. Dickinson's, and three reported by Dr.

¹ There is but one elderly person on the list, a woman aged fifty-four, who had had chorea for four years. (Dr. Dickinson, *loc. cit.*, No. 15.)

Peacock), seven had a rheumatic origin. Selecting out of the thirty-two eighteen who died directly of chorea (viz., five of Dr. Hughes', ten of Dr. Dickinson's, and all three of Dr. Peacock's), we get three—a male and two females, *all adults*—where the fatal disorder was of rheumatic origin. These numbers corroborate what I have before maintained in this journal—viz., that acute rheumatism, although having but a small share in chorea, is nevertheless veritably associated with it, and especially with its fatal form at the puberty age.

Coming now to the morbid associations of chorea in so far as they are revealed post-mortem, the evidence before us fully bears out the belief expressed by the late Dr. Kirkes in 1863, "that further experience would still more positively demonstrate that an affection of the left valves of the heart with the presence of granular vegetations upon them is an almost invariable attendant upon chorea, under whatever circumstances the chorea may be developed." The singular accuracy of this description, the need of "almost," and the justice of applying the observation to chorea of whatever origin, and not limiting it (as some would do even now) to rheumatic chorea, or even to chorea fatal as such, will be seen in what is now to be said. Out of all the cases in which the condition in question is especially mentioned I can find but five where the heart valves and pericardium are reported healthy, one of these being an elderly woman. Wherever the heart is affected the mitral valve is affected; the aortic valves are implicated often, the pericardium sometimes. This heart affection occurs equally in those that die in connexion with chorea, and in those that die directly of it. Thus, of Dr. Dickinson's twenty-two there are, as I reckon, twelve dying *with*, but not *of*, chorea; of these ten have mitral valve vegetations, and two have not. Of the ten dying *of* chorea seven have vegetations, and three have not. In Dr. Peacock's three cases, all dying *of* chorea, two have vegetations, and one has not. The valve deposit, which for shortness I thus name, may be either old or new, and variously connected with the mitral valves on their auricular side. The condition would seem to be an accident of the disease it accompanies, having but little apparent connexion with its fatal result. It so happens that of the five cases just mentioned as being the only examples of chorea occurring with perfectly healthy heart, all save one, the old woman, are typical instances of deaths in and by chorea. Three were girls at about the puberty age (Nos. 1, 5, and 8 in Dr. Dickinson's table), and one is a girl of Dr. Peacock's, aged twelve (St. Thomas's Reports, vol. viii., p. 29).

With the exception of this observation in regard to the heart and pericardium, there is little to be gathered in the material now before us as to the morbid anatomy of fatal chorea. I need not now refer to Dr. Dickinson's investigations as to the minute nervous changes in seven of the cases here mentioned, nor to those of Dr. Tuckwell upon embolic plugging, in the paper above quoted. Speaking generally, it must be said that the state of the brain and cord is not described in sufficient detail to be instructive. In a large proportion the brain, in a few the cord, is described as "congested." In the case of the boy to whom I have alluded as the single example of the kind in my own experience or in these tables, it was observed that "the grey matter of the cord was altered and yellow in patches," but there was no minute examination.

How far the foregoing particulars may serve to fortify or disturb pathological doctrines I do not now inquire. Their practical teaching is obvious. We are justified upon this evidence in looking upon severe chorea at the puberty age, especially in connexion with sexual excitement or with acute rheumatism, as a dangerous disorder apt to terminate fatally. It is true that we do not number many fatal cases, but it is also true that we do not meet with many, whether fatal or otherwise. The condition of such patients is the more precarious when, as is commonly the case, there is emotional as well as motor disorder. Such nervous exaltation, which is commonly altogether absent in the more familiar chorea of childhood, is with these both the sign and the source of danger. They are in a state of extreme sensitiveness, and lay hold of trivial circumstances to aggravate their disquiet. The smallest incident, the conduct of bystanders, undeserved reproach or ridicule, or even the sight of a patient affected like themselves, will often have its immediate prejudicial influence in a degree which those who have little experience of this kind of convulsion (whose actual title to the name of chorea, as Dr. Bright's cases

show, is often far from obvious) will find it difficult to believe. The question arises whether in these circumstances we address our treatment sufficiently to this mental state.

But the facts before us have this further teaching. If we exclude puberty, chorea of whatever violence is hardly dangerous to life. If we exclude both puberty and the female sex, chorea of whatever violence is not dangerous at all. Now violent chorea is by no means uncommon with boys. Thousands of examples of it must be comprehended within the period we are now reviewing. And yet in all that time, and from so many fields of observations, we get but one boy, aged eleven, dying of chronic chorea after five months, and probably with sclerosis of the cord. Chorea therefore, we may say, extremely rarely fatal in little girls, is, practically speaking, never fatal in little boys. If we add to this, what will not be denied, that permanent disablement from chorea is very uncommon, and that there is no treatment that even pretends to avert such after-effects, we get a strong argument in favour of leaving childish chorea alone. This conclusion will be further strengthened by a perusal of the valuable papers published in THE LANCET of Nov. 18th, 1876, by Drs. Tuckwell and Gray, upon "The Expectant Treatment of Chorea."

The conclusions to be derived from the foregoing review may be expressed as follows:—

1. Chorea, regarded as a disease of itself fatal, belongs almost exclusively to puberty, and especially to female puberty; its immediate exciting cause having distinct reference, in many instances, to conditions of unusual sexual excitement.

2. Besides the operation of sexual causes mental disturbance has to be reckoned; not fright only, but worry, anxiety, and despondency also, while the force and influence of such impressions is to be seen in the course as well as in the origin of fatal chorea.

3. Acute rheumatism appears as a cause of fatal chorea in but a small proportion of cases; yet the association, infrequent as it is, is distinct and unquestionable.

4. Chorea in its fatal, no less than in its non-fatal forms, shows strong preference for the female sex at all ages. Children, however, very rarely die of it, and boys, practically speaking, never.

5. Mental excitement, in varying degree (although not amongst the symptoms of ordinary chorea), is met with in so large a proportion of its fatal examples that we are justified in regarding this concurrence as of bad augury.

6. "Vegetations," new or old, on the auricular surface of the mitral valves, with or without similar deposit on the aortic valves, and sometimes with pericarditis, are met with in the great majority of cases dying of, or with, or shortly after, chorea. This condition, however, does not, as a rule, contribute directly to the fatal issue; it is found equally amongst those that die *with* and those that die *of* chorea. In some of the most marked and typical cases of fatal chorea the valves of the heart have been found absolutely healthy.

7. There is no other morbid condition, except that which concerns the heart, occurring with sufficient frequency or uniformity to be regarded as characteristic of fatal chorea.

Wimpole-street.

OBSERVATIONS IN URINARY PATHOLOGY AND THERAPEUTICS.

By C. H. RALFE, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL, SENIOR PHYSICIAN
TO THE SEAMEN'S HOSPITAL, LATE TEACHER OF PHYSIOLOGICAL
CHEMISTRY IN THE MEDICAL SCHOOL OF ST. GEORGE'S HOSPITAL.

II. A FORM OF DYSPEPSIA USUALLY ASSOCIATED WITH AN ALKALINE CONDITION OF THE URINE.

WHEN human urine becomes alkaline it is due to one or other of the following conditions: 1. To excess of the alkaline carbonates of potash and soda; a condition that frequently occurs normally after the ingestion in large quantities of vegetables and fruits. 2. Excessive elimination of the phosphates of the alkaline and earthy bases under conditions that have not been yet thoroughly studied, but which are not unfrequently found preceding or even accompanying saccharine diabetes; or sometimes, as has recently

been suggested,¹ forming a distinct disease. 3. By the formation of ammonia in the urine from decomposition of urea. Now the reaction of healthy human urine collected throughout the twenty-four hours is acid, but if separate samples of the urine passed during this period be taken, considerable variations in the character of the reaction will be observed. The constancy with which these variations occur under different diurnal physiological conditions was first studied by Dr. Bence Jones. That physician pointed out that the acid reaction of the urine increases and diminishes inversely with the secretion of the gastric juice. He found by examining the urine at short intervals during the day that an increase of acidity was observed in the urines passed before meals, and that a decline in the acidity occurred shortly after food had been taken, and acid was consequently withdrawn from the system; its maximum decline being attained in about three hours, when the acidity begins to rise. In some instances not merely was there depression of the acidity, but the urine became neutral and even alkaline. These observations of Dr. Bence Jones have been repeatedly confirmed by subsequent investigators; and the ebb and flow in the intensity of acid reaction of the urine, to which the term *alkaline tide* has been aptly applied, is a recognised physiological fact, though explanations different from that offered by Dr. Bence Jones have been advanced to account for the phenomenon. Dr. Roberts,² for instance, is disposed to attribute the occurrence of the alkaline tide after meals to a different cause—namely, to the entrance of the newly digested food into the blood. For if, as he says, the normal alkalescence of the blood is due to the preponderance of alkaline bases in all our ordinary articles of food, a meal is *pro tanto* a dose of alkali, which must, for a time, add to the alkalescence of the system, and consequently of the urine. Dr. Bence Jones's view receives considerable support from clinical and physiological experience. Since in those cases attended with frequent vomiting of intensely acid fluid it has often been noticed that the urine passed immediately after the ejection of the fluid becomes alkaline; the same effect is produced in dogs experimentally when pounded glass or other indigestible substance is introduced into the stomach to provoke the secretion of the gastric juice, which is withdrawn as soon as secreted by washing out the stomach with water by means of a stomach-pump, showing in both instances that the alkalinity of the urine was caused by the withdrawal of acid from the stomach, and not by the addition of alkali to the blood. That the ingestion of food, especially vegetable food, contributes, in a slight degree, in the production of the alkaline tide is very probable, but that it is mainly concerned in the phenomenon is out of the question, otherwise the alkalinity of the urine would be in direct proportion to the quantity of food ingested, which is certainly not the case. Indeed, the acidity of the urine can be depressed, and even rendered highly alkaline, otherwise than by the withdrawal of acid from the stomach, or by the ingestion of food. And it is this circumstance, hitherto unexplained, that has rendered many physiologists unwilling to accept Dr. Bence Jones's as a complete solution of the phenomenon. Dr. Hermann Weber,³ some years ago, observed that whilst breakfast decidedly had an influence in lowering the acidity, yet when he went without that meal the acidity was still lessened, though not to so great a degree. This observation of Dr. Weber I have repeatedly been able to confirm, the mere act of rising always producing a decided depression in the acidity of the urine. The use of the cold douche, or sweating in the vapour bath, both have the same effect, quite independently of food or the activity of the stomach.

There is another channel, however, by which acid is withdrawn from the blood besides the gastric secretion, and that is by the lungs. In the explanations hitherto advanced to account for the phenomenon of the alkaline tide in the urine this fact has not received attention. Dr. Edward Smith, in his researches "On the Elimination of Carbonic Acid" showed conclusively that the exhalation of carbonic acid by the lungs is increased by food and diminished by fasting, and that the amount exhaled during sleep is considerably less than is set free in the waking state. It therefore happens

that the time when most carbonic acid is being exhaled corresponds with the time when observers have noticed a decided diminution in the acidity of the urine, whilst the circumstances that diminish the exhalation of carbonic acid—namely, sleep and fasting, are attended by a rise in the acidity of the urinary secretion.

In health, therefore, it is probable that the exhalation of carbonic acid, in conjunction with the withdrawal from the blood of acid for the gastric secretion, and the direct ingestion of alkaline bases, aid in producing the alkaline tide in the urine. In disease, however, circumstances may modify or reverse the action of one or other of the conditions, so that although the variations of the acidity of the urine are frequent and often intensely marked, no connexion either between increased secretion of the gastric juice, the ingestion of food, or the exhalation of carbonic acid by the lungs can often be made out. Thus, for instance, in many pulmonary affections, in convalescence from many acute diseases, such as typhus, enteric fever, scarlet fever, pneumonia, &c., and in certain forms of dyspepsia, the urine remains persistently alkaline for many days together. The reason of this is not difficult of explanation, for in these diseases there is diminished supply of food and metamorphosis of tissue going on in the body, so that the salts which are concerned in maintaining the acidity of the urine are not separated to the same extent as in health. On the other hand, although from the feebleness with which the respiratory act is performed one would suppose that from less carbonic acid being exhaled by the lungs, the urine would maintain its acidity; yet it is not improbable that there being but rarely a temporary increase in its exhalation, in these cases, from the usual physiological stimulus of food and activity, the kidneys aid the lungs in getting rid of carbonic acid by separating it in its stable form (i.e., in combination with alkaline bases in the form of carbonates of potash or soda). Whatever may be said against the hypothesis, it is a fact that these urines nearly invariably effervesce on the addition of dilute acid, thus indicating the presence of carbonates in the urine. Urine alkaline from the presence of fixed alkali has been generally attributed by writers on urinary pathology chiefly to excessive elimination of the alkaline phosphates, and slightly to those of the earthy; and no author, with the exception of Prout, has mentioned that the urine may be pathologically alkaline from the presence of the carbonates of potash and soda. Prout observes:—"There are several distinct forms of disease connected with derangements of the soluble alkalis in the urine independently of the phosphates." And he further observes in these cases, that "the earthy phosphates are rarely entirely absent, but their quantity seems to be below the standard quantity of health, while the quantity of soda, potash, and ammonia appears to be in excess, or, strictly speaking, the carbonates of these alkalis appear to be in excess, hence such urine generally effervesces strongly on the addition of an acid." Prout, however, did not distinguish in his observations between the alkalescence caused by the carbonates of soda and potash and that produced by volatile alkali, carbonate of ammonia. Of twelve cases which have come under my observation, in no instance was the alkalescence due to carbonate of ammonia. In four cases the carbonates of potash and soda were associated with considerable excess of the earthy phosphates—cases resembling in many respects those described by Dr. Tessier of Lyons as not unfrequently preceding or accompanying saccharine diabetes, or sometimes running a distinct course, and to which I hope to refer on some future occasion. Of the remaining eight cases the alkalescence of the urine was due entirely to the presence of the alkaline carbonates, the alkaline and earthy phosphates being either normal or diminished in quantity, and no trace of either carbonate or free ammonia being discoverable.

(To be continued.)

DEATH FROM HYDROPHOBIA.—An inquest was held last week at the Mater Misericordiarum Hospital, Dublin, on the body of a man named Reid, who died on the 5th inst. in the Hospital from hydrophobia. Deceased was bitten on the nose in March last by a strange dog, but the matter was forgotten until a few days before his death, when the usual symptoms of the disease presented themselves.

BRIEF NOTES OF A VOYAGE TO BRAZIL.

By THOMAS B. PEACOCK, M.D., F.R.C.P.,

HONORARY CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL, AND
CONSULTING PHYSICIAN TO THE HOSPITAL FOR DISEASES OF
THE CHEST, VICTORIA PARK.*(Concluded from p. 4.)*

FROM the shortness of my stay in Rio, and from the extreme heat of the weather, I was not able to see so much of the public institutions as I could have wished to do. I visited, however, the general hospital, "the Santa Casa da Misericórdia," and the Leper Hospital, Imperial Hospital dos Lazaros. The former institution embraces the character of an infirmary as well as of a hospital proper. The first of its rules states that it is "instituted for the reception of all sick poor in the city of Rio, without distinction as to nation, condition, or religion." The hospital is situated close to the bay at the Praia de Santa Luzia. It was originally a Jesuit convent, but the old buildings have been entirely removed and replaced by the present hospital. The erection was commenced in 1840 and completed at the end of June, 1877. It consists of buildings arranged in a quadrangular form, the included space being crossed from end to end and from side to side by other buildings, so as to leave intervening spaces laid out as gardens, and which are rich in the profusion of tropical vegetation. In the centre of the front, on the ground floor, there is a large hall, from which the administrative offices open on each side, while at the back there are corridors leading to the lower wards, and a staircase which communicates with a fine room occupying the whole centre of the building on the first floor, and called from the statue which it contains the Emperor's room. On the same floor there are other apartments, employed for the meetings of the managers, and ornamented with full-sized portraits of various benefactors of the charity.

The wards for the reception of the patients occupy the outside of the building, and the wings which cross from end to end of the central space. The wards are long and lofty, and have large windows on the outside, and folding doors opening into wide corridors on the other side. They contain from thirty to forty beds each, two beds being placed in the piers between each pair of windows or of folding doors. The corridors have windows on the side opposite to the folding doors, and corresponding with them, so that the greatest facility is afforded for the perfusion of air through all parts. The superficial space is less than would be here thought necessary, but the cubic space is large from the great height of the wards. In the climate of Rio, where doors and windows can be constantly kept open, the space is probably very ample. The sides of the wards for from four to six feet from the floor are lined by blue and white tiles—"azuleos," and the floors are formed of dark-coloured ornamental woods, inlaid and polished. The building is two stories high, and the medical cases are placed on the ground floor, the surgical on the first floor.

From the reports published by the administrators, it appears that since October, 1871, the *personnel* of the hospital has consisted of a medical director, a vice-director, four resident physicians and three house-surgeons, of whom one is an ophthalmic surgeon, together with twelve visiting physicians and three surgeons, who are members of the Medical Faculty of the University. There are also special medical officers for the private rooms, and for the children and aged persons, with resident clinical clerks and dressers, who are students of the Medical Faculty. The wards are under the charge of French Sisters of Charity, of the order of St. Vincent de Paul; but the cleaning is done by hired servants, and there are two male attendants in each male ward. I found an English lady among the sisters, and understood that she had been several years in the order. I spoke to many of the English and American patients whom I found in the wards, and received the most satisfactory testimony to the kindness and attention which they received from everyone connected with the establishment. I was also assured that their religious views were in no degree interfered with.

Under the same management with the Misericórdia Hospital there is a Foundling Hospital, an orphanage and a

lunatic asylum, the Hospício de Pedro II. There is also the Hospício de Nossa Senhora da Sauda, which is apparently used as a casualty hospital to receive special cases in times when epidemics are prevailing. In 1875 and 1876 it received a large number of cases of yellow fever and small-pox. When also yellow fever is unusually prevalent local infirmaries are provided under the administration of the Misericórdia Hospital, at the expense of the Imperial Government, in different parts of the city of Rio.

The Misericórdia Hospital is maintained partly by funds which have descended to it from the convent to which it has succeeded, partly by donations and bequests, and partly by a monopoly which it possesses of the right to conduct the funerals of all persons dying in Rio, and also by lotteries. There are also private rooms in the hospital into which persons are admitted on payment. Every part of the hospital was scrupulously neat and clean, and altogether it may be pronounced to be admirably constructed and most excellently managed; and it is an institution of which any country might well be proud. Elaborate reports are published by the Brazilian Government of all matters connected with the financial condition and medical management of the hospital, and they are very liberally distributed to visitors. It appears that in 1877 and 1878 the number of patients in the hospital at the commencement of the official year, in July, was 1048. There were admitted during the year 14,043, making a total of 15,091; of this number 2232 died, giving a rate of mortality of 14 per cent. In the official year 1878-79 the number of patients treated was 13,870; and of these there were cured 9556, relieved 1892, not relieved 190, and died 2322—showing a rate of mortality of 16 per cent.

The report of the Misericórdia Hospital for 1873-7 is accompanied by reports of the Hospices and Infirmarys for the treatment of the cases of yellow fever. The infirmaries were five in number, and during the period of about four months in which in 1876 yellow fever prevailed they received a total of 1634 patients, of whom 620 died, giving a mortality of 38 per cent.; but it is stated that many of the patients were moribund at the time of their admission. The mortality varied considerably in the different hospitals, ranging from 32 per cent. in Santa Anna and Santa Rita to 48 per cent. in the Visitação. The cases in the Hospício de Nossa Senhora da Sauda had a mortality of 43 per cent. The reports—especially that of Santa Rita—contain some interesting details as to the mortality of the epidemic under different circumstances, such as the ages of the patients, the periods during which they had resided in Brazil, and the duration of the attack at the time at which they came under treatment. Between the ages of seven and fifteen the rate of mortality was 34.1 per cent.; between sixteen and twenty-five it was 21.6; between twenty-six and forty 45.2 per cent.; between 41 and sixty 47 per cent. In persons who had been resident in Rio for periods of one year or less the rate was 42.9 per cent. In those who had been in the city for various periods exceeding one year the rate was only 16.1 per cent. In persons admitted into the hospital after being ill for only one day or a shorter time the rate of mortality was 27.7 per cent. In those who had been ill from two to four days it was 37.3 per cent.; and in those ill for periods exceeding four days it was 42.1 per cent.

The Hospício de Nossa Senhora da Sauda received also during the year 1875-76 329 cases of small-pox, and of these 133 proved fatal, or 40 per cent., while forty-five cases of varioloid all recovered.

I also visited the Leper Hospital—the Imperial Hospital dos Lazaros. This is also partly an old building, a suppressed convent, and partly of recent erection. It is situated in the district of San Christavoa, on a slightly elevated knoll, close to the bay, of which the terrace in front of the hospital commands a beautiful view. It consists of a narrow centre, from which a long wing projects at each end. The wards are placed on the outside of the building, and a corridor runs on the inner side. In the old part of the building the wards only contain two beds; in the new part they are intended for a larger number—one ward contained ten or twelve beds, and afforded ample space. The new part of the building was in part built with funds obtained from the sale of decorations and titles. The hospital is supported by endowments, legacies, and donations. It is adapted for the reception of 100 patients, but at the time of my visit contained only forty. I examined the cases which I found in the hospital, but from having to conduct my inquiries through a gentleman who kindly accompanied me I was not able to make a satisfactory investigation. The cases were

described in the hospital case-book, which was shown to me, as cases of morphea, or elephantiasis of the Greeks, or the tubercular form of leprosy, and the subjects of the disease were white persons of Brazilian or Portuguese extraction, native negroes, and mulattos. There was also a case of the anæsthetic form in a native negro. The subjects of the disease were chiefly males, and the ages varied. Patients of whose cases I took notes were sixteen, eighteen, thirty, thirty-five, and thirty-six years of age. Taken as a whole, the cases were less marked and advanced than those which I saw at the Lisbon Leper Hospital in 1870.¹

I endeavoured to ascertain the generally-received opinion as to the probable causation of the disease, and was informed that it was generally ascribed to eating pork too exclusively, and in reference to the influence of a fish diet I was assured that the disease is very common in districts of Brazil where fish is not eaten—where, indeed, it is scarcely procurable.

In the return voyage we followed very much the same course as that adopted in the voyage out. We called in at Bahia and Pernambuco, sailed immediately on the west side of Fernando Noronha, so as to have a good view of that curious island, which, in the outward voyage, we had passed at night. We crossed the Line in 31° 15' W. long., coaled at St. Vincent, and then sailed to the westward of the Canary Islands, instead of through the group, as we had done in going out, passing close in on the west side of Ferro and Palma, and having distant views of Gomera and Teneriffe, the peak of the latter rising abruptly as a cone out of the sea, and being very distinctly seen at the distance of 90 to 100 miles.

In the outward voyage we left Southampton in the afternoon of the 9th of February, arrived at Lisbon on the 14th, crossed the Line in longitude 31° 43' W. on the 24th, arrived at Pernambuco on the 26th and at Bahia on the 28th, and anchored in the harbour of Rio on the 1st of March. On the return voyage we left Rio on the 10th of March, called in at Bahia and Pernambuco on the 13th and 15th, crossed the Line on the 17th in longitude 31° 15' W., arrived at St. Vincent on the 22nd, at Lisbon on the 28th, and moored to the extension pier at Southampton on the afternoon of the 31st, thus occupying in the whole voyage fifty-one days.

In going out we felt it warm at the Canary Islands, hot at St. Vincent, and very hot from thence to Rio. In returning it was cool at St. Vincent, and decidedly cold at the Canary Islands, and thence to Southampton.

I performed the voyage in the *Tagus*, one of the finest vessels of the fleet of the Royal Mail Steam Packet Company, and I should do injustice to my own feelings if I did not express my satisfaction with the arrangements of every kind on board the vessel, and my acknowledgment of the kind attention which I received from Captain Arthur Gillies and all his officers.

In summing up the results of my voyage I may say that though many years ago I had been in southern latitudes, and have seen some very beautiful tropical scenery, I have never seen anything to equal the luxuriance of the Brazilian vegetation. I was repeatedly told that the period of my visit was the time of fruit, not of flowers, but to me the country seemed everywhere covered with flowers. Around Rio the hedges were yellow with the blossom of the alameda. At Tijuca the forest was purple with the flowers of the quaresma, or flower of Lent, a species of melastoma, and a large tree with bunches of bright yellow flowers, called by the natives cozeira, was also very abundant on the mountain side. The bread-fruit trees and the mangos are also very beautiful, and it is almost worth a voyage to Rio to see the avenues of royal or imperial palms, the *Oreodoxa oleracea*, in the Botanic Gardens.

One of the most interesting features of a sea voyage, and especially of a voyage in southern latitudes, is the opportunity which it affords for the observation of the heavenly bodies. The sky being generally clear, and the stars shining with a brilliancy of which in this climate we have very little conception. In this respect, however, my late voyage was, in some degree, disappointing. I was anxious to observe the disappearance of the Pole star beneath the northern horizon, and the first appearance of the cross in the southern hemisphere; but while in the northern tropic, however clear the sky might be during the day, it uniformly became obscured towards the evening, and at night was generally covered with clouds, so that after reaching the Cape Verde Islands till we were south of the Line and well into the south-east

trade wind, towards the coast of Brazil, there was scarcely a clear evening. This might possibly be owing to the very slight north-easterly trade wind which we encountered, causing the equatorial cloud belt to be extended to the north beyond its ordinary limits.

Voyagers to the south for the first time are generally very anxious to see the constellation of the Southern Cross, and usually find it to fall very much below what their imagination had pictured it. This feeling is well expressed by Madame Agassiz in her account of her husband's expedition to Brazil²: "We saw the Southern Cross for the first time. With the visible image I lost a far more wonderful constellation, which had lived in my imagination; it has vanished with its golden glory. . . . In its place stands the veritable constellation with its four little points of light." I had myself frequently seen the constellation before, and had a tolerably clear recollection of its peculiarities, yet I felt very anxious to see it again, and partook very decidedly of the disappointment which, when seen, it generally leaves. As a constellation it is certainly very inferior to some of the groups of stars in the northern hemisphere, and especially it does not compare favourably with Orion, which being an equinoctial constellation, was visible during the whole voyage, and shone in the tropics with a brilliancy which I do not recollect to have ever seen equalled. Though, however, the Southern Cross is not imposing as a separate constellation, the portion of the heavens which it occupies is very beautiful, being very thickly studded with stars which though small, are very distinct and brilliant, much more so than those which constitute the milky way. The Megalanic clouds are very curious, as is also the patch of sky near the Cross, to which, from its apparent blackness, sailors have given the name of the "Coal-sack." This darkness is due to the entire absence of stars visible to the naked eye in a space surrounded by sky thickly studded with them.

Altogether the voyage was very pleasurable, and the time which I spent at Rio passed very agreeably, and was only too short, thanks to the kindness of friends with whom I passed it; and I returned home refreshed and invigorated, both in mind and body.

OBSERVATIONS ON THE BLOOD IN ANÆMIA.

By JOSEPH W. HUNT, M.D. LOND.,

PHYSICIAN TO THE WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

FOR the past few years, and especially since Dr. Gowers introduced to the notice of the profession his modification of Hayem's hæmacytometer,³ numerous observers in this country have been studying the condition of the blood, under varying circumstances both in health and disease. In a previous number of THE LANCET (May 10th, 1879) I published the results obtained from repeated examinations of the blood in ten cases of anæmia, occurring in unmarried girls. Several hundred observations which I have made since the publication of that paper have served to confirm the results and conclusions there set forth, while their value has been enhanced and their interest increased through the fact that the use of Dr. Gowers' hæmoglobinometer has, in many of the cases, enabled the amount of hæmoglobin to be estimated as well as the corpuscular richness of the blood.

As this instrument is probably unknown to many, a brief description of it may not be unadvisable.⁴ The colour of the blood, diluted with distilled water, is taken as an index of the amount of hæmoglobin. The standard consists of a dilution of a hundred times, or twenty cubic millimetres of normal blood in two cubic centimetres of water. (Owing to the instability of the standard dilution of blood, glycerine jelly tinted to correspond with a mixture of carmine and picocarmine of ammonia is used in its place.) The same volume of the blood to be tested is diluted till its tint is the

² Boston, 1879, p. 29.

⁴ Clinical Society's Transactions, vol. xii., pp. 64-67.

¹ See THE LANCET, 1870.

same as the standard, and the degree of dilution necessary for this indicates the relation the hæmoglobin bears to that of normal blood taken as 100. Thus, if a dilution of 50 times gives the same tint as that of normal blood diluted 100 times, the amount of hæmoglobin is just 50 per cent. of the normal. The two solutions are best compared by means of transmitted light and not by reflected, as unfortunately was done in most of the cases presently to be referred to, and therefore in comparing my results obtained by the hæmoglobinometer with those which may be afterwards published by others, it must be borne in mind that they are from 5 to 10 per cent. higher than those obtained directly by transmitted light.

And here I would say that though at first I was struck by what I considered to be the inefficiency of the hæmacytometer and the hæmoglobinometer, and regarded them merely as scientific toys, a more extended use has fully persuaded me of their great value. Each requires a certain amount of practice before the results obtained be thoroughly trustworthy, but that practice once acquired, and it is soon and easily done, I believe the results to be perfectly reliable, and to be of use, not only from a pathological standpoint, but also from a clinical aspect, both with regard to prognosis and treatment.

In examining the quality of the blood we must remember that, besides its richness in corpuscles and in hæmoglobin, a third factor must be regarded—namely, the amount of serum which dilutes the hæmoglobin and the corpuscles. In many diseases, doubtless, these latter are reduced out of all proportion to the serum, but in other diseases, and especially, as far as I have seen, the acute specifics, such as scarlet and typhoid fevers, all these constituents of the blood appear to suffer in about equal proportions. This observation is confirmed by others made by Drs. Buchanan Baxter and Willcocks lately published.⁵

Thus by the hæmacytometer and hæmoglobinometer we are unable to compute the amount of corpuscles and hæmoglobin in the blood, but only the proportion which these bear to the serum.

Greater experience has fully convinced me of what I hinted at in my former paper, that our estimate of the number of white corpuscles is considerably above the mark. The maximum number has been stated as '3 per hæmic unit, represented by two squares of Dr. Gowers' hæmacytometer—that is, 1500 corpuscles in the cubic millimetre of blood, but I believe that they very seldom exceed '2 per hæmic unit, and more frequently than not fall even below this. The average corpuscular richness of the blood in anæmia, as shown by observations in thirteen cases, all of which were at the commencement of treatment below 75 per cent., is about 63 percent.—a computation strikingly in accordance with my previously published results, where the average of ten cases was 62 per cent. As before pointed out by Dr. Gowers, myself, and others, the corpuscular richness of the blood is seldom accurately represented by the appearance either of the skin or mucous membranes. Not unfrequently have I examined the blood of young girls attending my outpatient room expecting to find a marked diminution in the number of the corpuscles, and, to my surprise, found it normal, or nearly so. Similarly, when at the commencement of treatment, the corpuscles may be considerably below the average, they regain the normal long before the symptoms have disappeared, and the patient has been restored to health. But though in such cases the corpuscles may be but little affected, the hæmoglobin is very far from being so. In nearly all cases the corpuscles became normal in from two to three weeks, while it takes three or four times that period for the hæmoglobin to reach anything like the usual percentage. For example, out of ten cases which I have charted with great care—observations being made weekly, and each case being so much improved that the patient no longer cared to attend,—in only one did the proportion of hæmoglobin exceed 90 per cent., in this case reaching 100 per cent.; while the average attained at the end of the treatment was only 70 per cent. The length of treatment varied from three to ten weeks, the average being six weeks. These facts are in the most striking contradistinction to observations made by Hayem. According to him, in anæmia treated by iron the hæmoglobin increases out of all proportion to the corpuscles—so much so that the richness in hæmoglobin may exceed the richness in corpuscles. Notwithstanding my very numerous experiments, I cannot recall

to my mind, and certainly I have no notes of, any case in which the richness in hæmoglobin at any period of the treatment ever equalled the corpuscular richness—indeed only once has it come within 10 per cent. of it. In regard to this point, Drs. Baxter and Willcocks⁶ similarly are in opposition to Hayem, and record results very similar in many respects to mine.

The amount of hæmoglobin at the commencement of treatment, as noted in fifteen patients, averaged 44 per cent., eight of these being 40 per cent. or below. Though, as remarked above, the corpuscles become normal in number long before the hæmoglobin, yet under judicious treatment the latter steadily increases in amount—about the same rate *proportionately* as the corpuscles. Thus, out of fourteen cases in which both the amount of corpuscles and the hæmoglobin were noted at the first visit, the former averaged 79 per cent. and the latter 44, a proportion of very nearly 9:5. After a week's treatment the percentage of ten of these was noted as 86 of corpuscles and 51 of hæmoglobin, a proportion of 8½:5; and after a second week the corpuscles had risen to 95 and the hæmoglobin to 55—that is, 8½:5.

In occupation these patients were mostly general servants, barmaids, pupil teachers, shop-girls, dressmakers, and such-like; and in age they varied from fifteen to twenty-five years old. In most of them there were hæmic murmurs heard at the base and in the carotids and jugulars; and in some apical murmurs, probably due to a temporary dilatation of the left ventricle, rendering the closure of the mitral valve imperfect; while increased tension in the pulmonary circulation was in many cases indicated by an intensified second sound heard at the pulmonary cartilage. As far as I have seen, hæmic murmurs have been not seldom absent when the corpuscular richness and the amount of hæmoglobin have been much below the normal. This requires further observation, and would be difficult of explanation unless under the supposition that there is a large excess of serum present, which, while it serves to dilute considerably the corpuscles and the hæmoglobin, helps also to maintain the quantity of the blood unaltered, and causes therefore no difference in the relationship between the quantity of fluid and the containing bloodvessels, which would be essential, according to many, for the production of hæmic murmurs.

I have watched with much interest the relation which the corpuscular richness of the blood bears to the catamenial periods. To do this exactly, of course, is difficult when patients are seen only once a week, as in most of my cases; but it appears to me that the catamenia generally diminish the number of corpuscles. This diminution is most marked if the blood be examined shortly before the onset of a menstrual period, though it is also found if the blood be examined soon after. This observation has been so frequently made that it cannot be a mere coincidence. Thus, out of twenty-two instances in which the blood was examined within three or four days either preceding or subsequent to the catamenia, in only three was there a continuous rise in the number of the corpuscles, while in four the previous rise was arrested, and in the remaining fifteen there was a distinct diminution either just before or after the onset of the catamenia. The amount of hæmoglobin appears to be less affected by the catamenia, and I have similarly noticed that it is less affected by other disturbing conditions which cause a decrease in the number of corpuscles. In other words, while the rise in hæmoglobin is not so rapid as the rise in corpuscles, it is more steady, and not so much affected by adventitious circumstances.

The treatment of the various cases differed considerably. In most, in addition to hygienic treatment, iron in some form or other was tried. The old and well-known compound mixture of iron, or Griffiths' mixture, gave as good results as any. The tincture of perchloride of iron was very valuable, and especially so when given in fairly large doses—fifteen to twenty minims. When given in smaller doses, as five minims, it did not effect nearly so much improvement in the blood condition. As a matter of experiment, arsenic (Fowler's solution) was tried in a number of cases by itself; though it occasionally effected a considerable rise in the number of corpuscles, this rise was very unsteady and liable to great fluctuations and relapses. Arseniate of iron, given in doses varying from one-sixteenth to one-third of a grain, frequently much improved the general condition, but did not effect any marked or steady change in the blood

⁵ THE LANCET, March 13th, 1880.

⁶ THE LANCET, March 20th, 1880.

condition—a fact easily accounted for by the small amount of iron present in the preparation.

In conclusion, I shall shortly relate the history of one patient. She was about twenty-one years old, engaged as a general servant, and had suffered from a want of good food and clothing. She came to my out-patient room complaining of headache, giddiness, palpitation, amenorrhœa, and the other usual symptoms of chlorosis. She was admitted as an in-patient on January 16th, when the hæmacytometer showed the percentage of corpuscles to be only 45. As a matter of experiment, she was ordered no medicine beyond a little camphor-water, but was put on good nourishing though plain diet. This was continued for a fortnight, during which time, though the general condition much improved, the corpuscles only rose 10 per cent. (to 56 per cent.) She was then ordered Fowler's solution of arsenic (five minims three times a day), with the same diet, for a week, during which time the number of corpuscles fluctuated considerably, rising at first to 64, but afterwards sinking again to 57 and finally to 52 per cent. She was, lastly, ordered iron on Feb. 3rd; from which time the corpuscles speedily and steadily rose in number, rising in three weeks nearly 60 per cent.; in other words, reaching 110 per cent. on Feb. 24th. As the catamenia had been absent for a long time, she was now ordered the liquid extract of ergot, and the iron omitted. During this period the corpuscles sank to 96 per cent., but, on the iron being resumed, rose again in three days to 102 per cent. At this point the catamenia recurred, and the corpuscles again sank to 96 per cent. immediately afterwards. This case is not chosen as being an especially favourable one; indeed, it is only typical of many others; and is chosen because it is the only one in a patient in whom frequent observations were made over a length of time. Subjoined are all the observations made.

Wolverhampton.

A FEW PRACTICAL REMARKS ON THE

TREATMENT OF TROPICAL DYSENTERY.

By J. H. COURTENAY, L.R.C.P. (LOND.), L.K.Q.C.P.I.
GOVERNMENT MEDICAL OFFICER, LUCEA, JAMAICA.

To those who have read the published writings of many eminent East Indian medical practitioners, it must be a matter of some surprise that the brilliant results they have obtained from the ipecacuanha treatment of dysentery should not have caused a universal belief in its efficacy, but that this remedy has not been had recourse to in the West Indies, unless in a few exceptional instances, I could give abundant proof.

Some practitioners whom I consulted when I first had to deal with this disease recommended acetate of lead and opium; others advocated calomel and opium; others, small doses of ipecacuanha and opium. Within the past three years I have had to treat upwards of 200 cases of dysentery, and I can safely assert that until I absolutely adopted the ipecacuanha treatment my results were anything but satisfactory, and since then some of the most apparently hopeless cases have made a rapid recovery.

The chief difficulty that young practitioners experience is

their inability to follow one definite line of treatment, so many varieties of administering ipecacuanha are advocated by the different writers on the subject. If I may, without presumption, attempt to simplify this variety of treatment, I think the best means to accomplish this end will be to make a brief statement of the course that experience and a careful study of the writings of others have led me to pursue.

As a preliminary measure, if the dysenteric phenomena have not displayed themselves in too marked a degree, I order half an ounce of castor oil with ten or fifteen minims of tincture of opium; the patient to be kept quiet and abstain from all solid and irritating food. This failing to check the disease, absolute rest in the recumbent position must be enjoined, twenty to twenty-five minims of the sedative solution of opium administered, and in twenty minutes afterwards thirty grains of powdered ipecacuanha in an ounce of water or syrup of orange-peel. The patient must then be kept perfectly quiet and abstain from all food, fluid or solid, for two or three hours. If the ipecacuanha is vomited immediately after it has been administered allow an interval of about half an hour to elapse, and then repeat the full dose again. In the further treatment of the case ten-grain doses of ipecacuanha should be given every six hours until convalescence is established; and when it is, to guard against a relapse, it is a wise precaution to give five or ten grains at bed-time for a few nights. In addition to this treatment a two-ounce starch enema containing twenty to twenty-five drops of sedative solution of opium, given at bed-time, has an admirable effect in controlling tenesmus and inducing sleep. With regard to nourishment I have never found, in adopting this line of treatment, that the nauseating effect of ipecacuanha produced any alarming intolerance of food; of course, food of the lightest nature, such as beef-tea, chicken-tea, arrowroot, milk, and the like, should only be administered. I think the use of stimulants should be dispensed with unless there is extreme exhaustion, and even then they should be given sparingly and extremely diluted.

And now it will be asked, Does the ipecacuanha treatment never fail, and is it an absolute specific for dysenteric disease? I can unhesitatingly answer, as far as my experience enables me to do so, that in the great majority of cases it most certainly does not fail, and that its effects are often magical; but I have met a few cases where no precautions or varieties as to administering small or large doses of the drug seemed to be able to avert the absolute intolerance of it. Under these circumstances I administered a bismuth and soda mixture containing five drops of sedative solution of opium in each dose. I also gave a powder containing mercury with chalk and compound ipecacuanha powder every four hours, and an opiate enema at night. Several writers on the subject say that when this intolerance is present hepatic complications are to be dreaded, but happily in the cases I have alluded to no such difficulties had to be encountered, and they quickly yielded to treatment; but I consider that when a patient suffering from dysentery is unable to take ipecacuanha his chances of recovery are seriously lessened by such inability. My utmost expectations will be fully realised if this very imperfect outline of the treatment of tropical dysentery enables some new-comers to grapple with a disease that admits of no parleying with, and if the re-opening of the subject is sufficient at least to arouse the attention of those who feel a great difficulty in yielding up preconceived ideas.

THOMSON'S AMETROMETER.

By R. BRUDENELL CARTER, F.R.C.S.,
OPHTHALMIC SURGEON, ST. GEORGE'S HOSPITAL.

I AM desirous to call attention of the profession in this country to a very ingenious instrument, which Dr. Thomson of Philadelphia, its inventor, has named the ametrometer. It is intended to measure the refraction of the eye without the aid of lenses; and it appears likely not only to accomplish this object, but also to effect a great saving of time for those who are habitually engaged in such investigations.

The ametrometer consists of a graduated bar, about a foot long, pivoted near one extremity, and carrying two

very small gas jets, one of which is stationary near the pivot, while the other slides freely to and fro along the bar. The patient is placed five metres from the instrument, and the lighted gas jets are separated, the bar being in a horizontal position. To an emmetropic eye, or to an ametropic eye fully corrected, the two flames will appear clearly and sharply defined; but, to an unaided ametropic eye, each flame will appear surrounded by a luminous band or halo, produced by the dispersion circle on the retina. The width of this band will be the measure of the ametropia, the amount of which may therefore be read off upon the graduated bar by bringing the flames so near together that the margins of the two luminous bands come into contact. The patient is then directed to move a slip of coloured glass slowly over the pupil, from the temporal side inwards. If the case be one of hypermetropia, the temporal side of the halo will remain white, while the nasal side is coloured by the glass; and, if it be myopia, the reverse of these conditions will obtain. In astigmatism, the luminous bands will be elliptical instead of circular; and, by turning the bar upon its pivot, the two ellipses may be brought into such a relative position that their major axes, if touching, would be in a continuous line. The bar then coincides with the meridian of greatest ametropia, which may be measured by bringing the bands into contact in the ordinary way. The instrument is furnished with a graduated arc, upon which the angular position of the bar may be read off, and it may then be turned to a position at right angles with the former, and the refraction of the opposite meridian measured in turn. With a patient of ordinary intelligence, the examination may be completed with great rapidity. It is hardly necessary to say that the eye examined must be fully under the influence of atropine or of duboisin, and that the other eye must be covered.

The graduation of the bar is such that the refraction may be read off in inches upon one side of it, and in dioptres upon the other. For the latter, each division measures two and a half centimetres, and is again subdivided into two.

In testing upon myself unknown degrees of ametropia and astigmatism, artificially produced by lenses, I have found the indications of the instrument perfectly accurate, but I have not yet had sufficient opportunities of observing how far it is to be trusted in the actual ametropia of patients. In certain eyes, probably from irregularities of refraction in their lenses, the diffusion halo is extended in some directions by prolonged rays, and some care will be required in causing patients to discriminate between these rays and the boundary of the diffusion halo itself. On this and on some other points of interest I shall hope to be able to make observations worthy of future publication; and my present object is to enlist the aid of others in the work. The ametrometer either is, or shortly will be, obtainable from Mr. Hawksley.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF CANCER OF THE UTERUS TREATED BY CHIANTURPENTINE.

(Under the care of Dr. GRAILY HEWITT.)

For the following notes we are indebted to Mr. J. E. Hine, obstetric assistant.

Mrs. O—, aged forty-eight, married, two children, no miscarriages, was admitted April 28th. The catamenia had ceased three years and a half before. There was no family history of cancer. She first noticed a vaginal discharge one year before admission. The discharge became offensive, and increased in quantity during the last three months. Bleeding was first observed in February, and continued in varying amount. There had been constant pain in the back and right iliac region for a similar period.

On admission, the cervix uteri was very close to the

vaginal outlet, and presented a broad surface the size of a wine-glass, rough and excavated, with a very sharp hard edge. The cervix was welded firmly to the adjacent structures all around.

The emulsion of Chian turpentine, containing eight grains in each dose, was given three times a day. The patient took this regularly till June 10th, when, owing to vomiting, it was changed for the pill of Chian turpentine, five grains three times a day. Syrup of the iodide of iron was given at the same time. She had an opium pill at night to relieve pain. Vaginal injections of warm water and iodine were used.

On June 21st the edge of the os uteri was thinner than when previously examined, the result of the destruction of a portion of the thickness of the os. There was evidence of ulcerative action, but in other respects the condition remained much the same.

Whilst the patient was in the hospital she progressively lost weight. On May 7th she weighed 7st. 4lb.; on June 17th 6st. 11lb.

The discharge had been very abundant, clots frequently being passed. The pain had increased in severity. She suffered latterly from vomiting, rejecting nearly everything she took. Accordingly, nutrient enemata were given.

Note.—Though there is no evidence that the disease has extended either locally or generally, the patient is at present decidedly worse than she was a month ago.

LINCOLN COUNTY HOSPITAL.

CASE OF CANCER OF THE RECTUM; COLOTOMY; RECOVERY.—CASES ILLUSTRATING USE OF PLASTER-OF-PARIS BANDAGE IN HIP DISEASE.

FOR the following notes we are indebted to Mr. W. J. Cant, house-surgeon.

Cancer of rectum and vagina; colotomy.—S. W.—, a cachectic-looking woman, was admitted (under the care of Mr. Sympton) August 10th, 1879, complaining of difficulty in passing her motions, severe pain in the rectum and vagina, and frequent bleedings. She said that twenty-two years before she had a fistula, which frequently gathered and discharged, and had never thoroughly healed. She stated that she was losing flesh and appetite, and was very much troubled with constipation. In the beginning of the year 1879 she took a dose of castor oil. The bowels not having been moved for about one month, the oil acted freely; but she noticed that some of her motion was passed per vaginam. On examination a dense nodulated and ulcerated mass was found filling up the rectum and vagina, discharging a fetid sero-sanguineous fluid. The motions were passed with difficulty through a fistula connecting the vagina with the rectum. The pain became more and more severe, the sanguineous discharge more profuse, and the bowels more difficult to relieve.

On October 2nd, 1879, colotomy was performed. An oblique incision, four inches long, was made in the left lumbar region, the tissues were carefully divided, and the colon exposed, two silk sutures were passed through the integuments and the gut, which was divided between them and secured to the edges of the wound by the four silk sutures, after which eight metallic sutures were introduced, and the gut accurately adapted to the edges of the external wound. The wound was dressed with carbolic oil and tenax. Fæces passed through the opening every day without much pain; firm and well-formed motions were passed.

Four days after the operation the wire sutures were removed. The wound was then healing rapidly, and there was only a slight amount of inflammation around, and a little pain at the umbilicus. Ten days after the operation all sutures were removed, and zinc ointment was applied around the edges of the wound, which looked healthy. Her appetite gradually improved, the patient gained flesh and felt much stronger, and the pain and hæmorrhage had greatly diminished. About three weeks after the operation she was allowed to get up and move about, a convex waterproof pad being applied over the artificial anus, from which she had no pain.

She was made an out-patient Nov. 1st, when she was well enough to resume her ordinary occupation, in which she was still engaged on April 18th, 1880. The appetite re-

maintained good, and her strength was only slightly diminished, although the cancer was gradually increasing in size, and the pain was frequently felt, for which she takes twenty drops of solution of hydrochlorate of morphia occasionally.

Plaster-of-Paris bandage for hip disease.—The application of plaster-of-Paris splint in hip disease seems to afford an effectual and inexpensive method of treating this disease, maintaining complete rest for the joint, with extension, and giving the patient at the same time the benefit of moving about. It would seem to be equally useful in acute and chronic cases, giving great relief with usually rapid improvement in general health. It may be used in those cases where abscesses have formed around the hip-joint, whether discharging or not; in the former case an opening must be made in the splint. The mode of application differs very little from that employed by Dr. Sayre in spinal disease. A flannel bandage is wound firmly round the limb extending from a little below the knee to about one inch above the anterior superior spine of the ilium, the muslin bandages having had plaster rubbed into them are moistened and then applied. Plaster-of-Paris made about the consistence of cream with water should be smeared on during the bandaging to give extra firmness on drying. It is an advantage to have the patient suspended during the application. Both hip- and knee-joints are immovably fixed. An iron patten is fastened to the sole of the boot belonging to the foot of the healthy side, so as to raise it two or three inches from the ground, thereby allowing the leg on the diseased side to hang extended, motionless, from the body, when the patient gets about by means of crutches.

R. S.—was admitted with all the symptoms of acute hip disease. She had frequent elevation of temperature (100°) with exacerbations of pain and night startings. She remained in hospital for seven months, being kept in bed during the whole time with only slight improvement. The plaster-of-Paris bandage was applied and she was made an out-patient, being able to move about easily without any pain. In one month she was able to leave off the splint and walk without crutches, the movement of the joint being free. Her health was very much improved and was free from pain.

S. W.—was admitted with hip disease, having excessive pain on the slightest attempt at movement. The patient was kept in bed for six months and counter-irritation was applied round the hip without any marked improvement. The plaster splint was put on and she was able to move about without pain. The general health rapidly improved. The bandage was kept on for some time, as pain was complained of when the heel was conussed.

H. D.—had disease of right hip with a large abscess on the buttock. The patient was very emaciated and complained of great pain. The plaster splint was put on and the patient was made an out-patient a few weeks afterwards. He came to the hospital six weeks afterwards very much improved in health and was free from pain; he could move about easily with the crutches. The bandage was removed to see the condition of the abscess, which was found to have slightly enlarged. About six ounces of pus were taken away by means of the aspirator, and the bandage was again applied.

Reviews and Notices of Books.

The Hysterical Element in Orthopaedic Surgery. By NEWTON M. SHAFFER, M.D., Surgeon in charge of the New York Orthopaedic Dispensary and Hospital, Orthopaedic Surgeon to St. Luke's Hospital, N.Y. G. P. Putnam's Sons. 1880.

THE fact that severe diseases and distortions of the spine and joints may be very exactly simulated by the obscure condition usually known as hysteria, has been recognised by surgeons in only comparatively recent times. Brodie and Skey both mention it and describe cases, but Paget in this country and Esmarch in Germany have done more than any others to draw attention to a fact of very great importance and only too generally overlooked. The simulation of local organic disease may be and often is, so exact that only the most careful and, usually, repeated observation can establish the diagnosis, and probably most surgeons of experience are able to recall cases that they have mistaken before they

were sufficiently alive to the occurrence of this "neuro-mimesis." Dr. Shaffer's essay was originally read before the New York Neurological Society, but is well worthy of publication in its present form. Several cases of hysterical disease of the knee, hip, spine—simulating both angular and lateral curvature—and club-foot are described, and the points relied upon for diagnosis discussed. We can only briefly note those affirmed to be of most general application. While the age and sex have some weight it is well to remember that the male sex is not free from neuro-mimesis, nor is it infrequent before puberty, and it may be developed in patients who have no knowledge whatever of the symptoms of the disease feigned. Pain and muscular rigidity usually come on together, and the expressions of the former are often exaggerated and voluntary, while in the local disease rigidity precedes pain, and the pain shows itself in a peculiar expression of countenance and by involuntary signs, and often during sleep. Hysterical rigidity varies from time to time, can be overcome by continuous traction, or by drawing off the attention by sleep, opium, or chloral; the rigidity of joint disease is constant, cannot be overcome by traction, sleep, or narcotics, but only by complete anaesthesia. The muscles of the limb merely waste from disuse, and show no diminution of reaction to the faradaic current in hysteria, while in true joint disease there is exaggerated wasting and great loss of electrical reaction. In the simulated disease there is no alteration in local temperature nor swelling, unless from superficial hyperaemia and oedema, as from counter-irritants, and spots of hyperaesthesia both near the joint and at a distance are frequently observed. In hysterical disease of the spine there is no limitation of the natural movements if a careful examination is made, and the deformity often results from relaxation rather than spasm of muscles, and the scoliosis is unattended with rotation of the vertebrae. Hysterical talipes is peculiar in having flexion of the toes commonly superadded. Dr. Shaffer's illustrative cases are well and honestly reported, and although the author does not attempt to clear up the mystery in which these conditions are shrouded, he certainly marks out the way in which surgeons may best avoid confusing the so-called real and feigned joint diseases.

Elements of Modern Chemistry. By ADOLPHE WURTZ, Member of the Institute, Honorary Dean, and Professor of Chemistry of the Faculty of Medicine, Paris; Member of the Academy of Medicine, &c. Translated and edited with the sanction of the Author, from the fourth French Edition. By WM. H. GREENE, M.D. With 132 Illustrations. London: W. Swan Sonnenschein & Allen. 1880.

M. WURTZ's excellent little manual is already known in its original language to many English readers, the high and well-earned reputation of its author drawing instant attention in England to all his works. But Dr. Greene, who is evidently an accomplished chemist as well as a good translator, has done well to give us an English edition, adding thereby one more good elementary text-book to several which we already possess.

M. Wurtz is an experienced teacher, and has succeeded very well in giving enough and not too much matter to beginners, a task by no means easy. He has, moreover, judiciously blended the theoretical and the practical; and as the exposition is always clear, it is not wonderful that the book has been popular and useful. Nevertheless we cannot say that it is perfect, or even that it is better than some English text-books. The arrangement adopted in the organic portion is not happy, the nomenclature is in some cases inferior to that now adopted in England, and some important modern discoveries and theories are either omitted or too slightly noticed, especially if they do not belong to France.

THE LANCET.

LONDON: SATURDAY, JULY 17, 1880.

THE present meeting of the General Medical Council is by far the most discreditable meeting in its history. Before the meeting there was nothing to lead even judges to think that the Council could find excuse for sitting more than three days. The Executive Council had met less than a month before, and there seemed little in its references to the Council to occupy the latter body more than a few hours; but when the first programme of business appeared on the day of the Council's assembling, it was evident that the members had no intention of a short sitting. The programme literally bristled with questions which, when once opened, admit of indefinite discussion. These questions had reference chiefly to preliminary education. The first thing that the Council did was to spend two days in debating whether to put the subject into the hands of a committee merely to prepare it for discussion. Twenty-four of the leading members of the profession in the United Kingdom spent two days of their precious time, and £400 of the Council's funds, in making up their minds to have the subject put into shape for them on the third day. Of course in this discussion speakers aired all their views on the whole range of subjects, actual and desirable, included in preliminary examinations. At the end of the second day the Council arrived at the great conclusion to have a Special Committee to arrange for further high debate. This began on Friday and continues to the time of our writing. Every conceivable question was raised, from the claims of Greek to those of Dutch, and most of the questions were raised three times over, and the speakers had so many opportunities of repeating themselves. Sir WILLIAM GULL said very truthfully: "We fight our battles three times over, and never come to any result," and added plaintively: "We shall go on so *for ever*—yes, for ever, till time shall be no more!" Dr. ANDREW WOOD was more fortunate than Sir WILLIAM. He was struck with the humorous aspect of the situation, as Sir WILLIAM was the grave one, and even this redoubtable champion of the Council was constrained to say, when Dutch appeared on the scene, "This is really becoming ludicrous—where are the examiners to come from—are we to send over to Holland for one?" The ludicrousness and the gravity of the situation are not realised by merely studying the course of this debate. We have to consider that the Greek Question was the subject of an exhaustive debate in 1866, and that the subject of Mechanics was the subject of exhaustive debate and definite ruling only last year. Mr. SIMON and Dr. FERGUS in 1879 carried the resolution that the subject of Elementary Mechanics of Solids and Fluids—meaning thereby Mechanics, Hydrostatics, Pneumatics, and Hydraulics—be made compulsory. This year the Council resolves that there shall be an examination in the Elementary Mechanics of Solids and Fluids, and Mr. TURNER and Dr. ANDREW WOOD move—and carry their resolution—"That the examination

in the Elementary Mechanics of Solids and Fluids shall comprise the elements of Statics, Dynamics, and Hydrostatics. Hydraulics are left out in the cold, though what they have done since 1879 to merit such treatment is known only to the members of the Medical Council. But so the time is spent of twenty-four gentlemen than whom individually it would be difficult to find twenty-four more eminent or more estimable within the bounds of the profession, and so the money of the profession is wasted and squandered.

We must not be misunderstood. We do not mean to deny that the speeches have been good and the discussion interesting. Some of the speeches have been exceedingly able. Nothing could be better or more effective than Professor TURNER's account of the Examination in Arts in the University of Edinburgh; than Sir JAMES PAGET's discourse on the question of making Greek compulsory—we do not speak of the view or the argument, but of the speech as a speech; than Dr. HAUGHTON's strong Irish denunciation of all shams in the examinations; than Dr. ROLLESTON's repeated defences of the practical subjects as distinguished from those which an urgent age can dispense with, or than Mr. SIMON's vindication of Mechanics. But the Medical Council does not meet to hold fine discussions and to repeat its own conclusions. It professes to be an instrument for doing certain work, and it is constantly showing itself to be a most ineffective and costly instrument. As a debating club it would win a prize. As a medical authority it is condemned even by its own best members, and by the universal consent of the profession to which it owes all its importance. The question forces itself, Who is to blame for all this? Just when it is of supreme importance that the Council should behave itself with dignity and discretion it makes a most signal exhibition of the worst faults that were ever attributed to it by its most conscientious critics. Who is to blame? Answers vary. Some say the PRESIDENT; that he labours under a defect of force and power of leading and advising. We cannot but admit that the PRESIDENT lays himself open too constantly to such criticism. But he is by no means solely to blame for the discredit that has accrued to the Council by the meeting now concluding. There are other members of the Council who, by their personal character, their long connexion with the Council, and the recognised value of their time, would have been justified in appealing very seriously to the Council on the first day of its meeting. But they sat silent. Mr. SIMON made on Thursday, July 8th, an appeal, but it was an imperfect one. He should have proposed a motion expressive of the objections to the course the Council deliberately entered on. But he contented himself with a few words of earnest protest. He came in for severe castigation at the hands of Dr. ANDREW WOOD, and was not supported by members of the Council, from whom better things might have been expected.

WE learn from one of our Northern contemporaries that Mr. J. T. HIBBERT, M.P., the Parliamentary Secretary of the Local Government Board, replying to a question regarding the accuracy of certain statistics submitted to a public meeting of anti-vaccinators at Oldham, has written a letter of which the following is given as the text:—"It is scarcely fair to

say that 'in 1875 there perished in England 26,000 infants who would have lived had vaccination been as little in vogue as in 1874.' In the first place the increase of 26,000 deaths after allowing for increase of population, is caused principally by two diseases—viz., diarrhoea and bronchitis, the former having risen from 5143 deaths in 1874 to 15,477 in 1875, and the latter from 2506 deaths to 14,506, which together show an increase of 22,334 deaths. It cannot be said that either of these two diseases is largely influenced by vaccination. The deaths of infants under one year from small-pox have fallen from 1074 in 1874 to 142 in 1875, and while I admit that in 1871 and 1872 the deaths were 3161 and 2656, the average annual percentage of deaths from small-pox of infants under one year was largely diminished. On the other hand, the return shows an increase of deaths from syphilis of infants under one year from 255 in 1874 to 1554 in 1875, in my opinion one of the most unsatisfactory features in connexion with vaccination, and one which leads me to support the proposed modification of the Vaccination Law now before the House of Commons."

By what process of reasoning Mr. HIBBERT connects the reputed increase of deaths among young infants from syphilis with vaccination we shall not pretend to say, and do not care to conjecture. By far the most important consideration arising out of this letter (if we are to accept the text as accurate) is that the Parliamentary Secretary of the Local Government Board accepts without qualification one of the most pernicious and least justifiable assumptions of the anti-vaccinators. Further, he avers that so far as he is concerned with the Vaccination Acts Amendment Bill before the House of Commons, of which he is a promoter, he supports it because he regards the alleged increase of infantile syphilis as connected with the practice of vaccination! What relation between the provisions of the Bill and this question can exist is not easy to understand, unless it be conceived that Mr. HIBBERT sees in it the beginning of the end of compulsory vaccination. Be this as it may, we have the spectacle of the President of the Local Government Board justifying the Bill on the ground of political expediency, and the Parliamentary Secretary of the Board intimating, as it would seem, that he supports it on "anti-vaccination" grounds. This intimation must tend to cast doubts upon the real motives underlying the Bill, and will no doubt receive attention in its further progress.

Our own position in regard to the measure is well defined, and should be intelligible. We are concerned to [maintain the compulsory principle in full efficiency. If it were politically possible to enforce vaccination on the law-breakers, by having their children vaccinated under magisterial supervision, we would advocate that plan of procedure. To borrow an idea from the anti-vaccinators, the policeman should take the child from the mother and hold it while the beneficent operation, which in its principle and practice embodies the genius of *preventive* medicine, is performed. This policy is, however, in the present state of public opinion, impracticable. It remains, therefore, to look at the question from the practical standpoint, and viewing the matter thus, we feel that it will be an advantage to get rid of the grievance of multiple fines. Obviously nothing is gained to the cause of vaccination by the infliction of fines. The circumstance that the parent is

mulcted for the offence of refusing to have his child vaccinated does not protect it from the small-pox, or, in obstinate cases, procure compliance with the law. The law-breaker who will not obey the statute after two fines have been inflicted is not likely to do so afterwards. The first fine may be assumed to act as a warning to the negligent; the second has probably as much influence as it is possible to bring to bear on the obstinate. After this second infliction, unless the community is wise enough to enforce vaccination by direct means, it is simply creating a claim to martyrdom to pile up penalties. The law is, in fact, placed in the ludicrous position of having to tease its antagonist without being able to compel his obedience. A man who happens to have money at his command, either his own property or a fund placed at his disposal by some Society, may earn considerable distinction in the eyes of the unthinking crowd by his payments of fines, and if he chooses to put up with a few days' imprisonment as a first-class misdemeanant, he may become famous. This child's-play is the cause of infinite harm to the interests of public health. It tends to disguise the real position of affairs; and so falsifies appearances, that instead of seeking solely the good of the people, the law seems to be striving, vainly, to enforce a practice against which those who oppose it revolt. We further object to this misrepresentation because we are convinced that the parents who refuse to have their children vaccinated are few, and do *not* represent even a small class of society. There are always turbulent spirits in a large community, and at times when there is a lack of burning questions on which to "agitate" such persons will fall back on social questions. The *Anti-Contagious Diseases Acts*, the *Anti-Vivisection*, and the *Anti-Vaccination*, movements are the only opportunities for public excitement which just now offer themselves. If the grievance-mongers lose their "cry" by the passing of this Bill, we shall be glad, and the maintenance of the Compulsory Vaccination Acts will be assured. This is the view we take of the matter, and to the policy suggested by such a view we adhere.

It is not more difficult to cross Niagara upon a tightrope than to steer a course along that narrow channel which separates free-will from necessity, health from disease, insanity from criminality. For some days a man lay under sentence of death, concerning whom it had been proved that he suffered from what was probably a delusion arising from insanity; a wretched woman is committed for trial on a charge of murdering her maid-servant, and concerning whom it is admitted that she laboured under a similar delusion—viz., that she was watched by persons who intended to do her evil; a medical officer has been committed for trial on a charge of manslaughter, because, it is alleged, that he imposed insufficient restraint upon a man who committed a homicidal act (the man who committed the act being at the same time committed on a charge of *wilful* murder!); and a lady has been committed for an offence against the lunacy laws for receiving lunatics into an unlicensed house, and without orders or certificates.

The best comment we can make upon the custom which is prevalent, of allowing common juries to judge between criminality and insanity, is to call attention to the dilemma into which coroner and jury have fallen in the matter of the

Polish Jew who killed an inmate of the City of London Union Infirmary. The facts of the case are well known to our readers. A Polish Jew named SALEWSKAL, suffering from some form of delirium, was admitted to the infirmary, and was placed in the imbecile ward. Dr. BANCORBE, the medical officer, asked another of the inmates named HARRIS, who knew the Polish language, to go to the ward and converse with him, and at the same time he warned the attendant in the ward to "keep his eye" upon the Pole. During the absence of the attendant SALEWSKAL fractured HARRIS's skull with a chair and killed him. The result of the inquiry before the coroner is this, either that the jury recognise SALEWSKAL as a sane man and commit him for wilful murder (for it is obvious that no delirious patient can have any will), and at the same time commit the medical officer because he did not impose *unlawful* restraint upon a person capable of exercising both will and judgment; or that the jury recognise SALEWSKAL as a lunatic who ought to have been more carefully restrained, in which case the charge of manslaughter (against the medical officer) might possibly stand, but the charge of murder (against SALEWSKAL) most certainly could not be sustained. Supposing the latter view to be the more correct of the two, and supposing SALEWSKAL'S condition to be curable, what effect will the anxieties of his trial have upon his mental condition?

On the whole this is the prettiest sample of "crowners' quest law" which we have encountered for many a long day, and by their verdict the jury have done a terribly cruel thing either to a poor invalid who merits all our deepest sympathy or to a professional gentleman whose only fault has been that he did not break the law.

The offence for which Mrs. RUTLEY stands committed is for disregarding the 90th section of the Act of 8th and 9th VICT., chap. 100, by which it is enacted that no person (except a committee) may for profit take charge of a single lunatic without an order and certificates. Mrs. RUTLEY is also charged with receiving more than one lunatic into an unlicensed house. If these charges be proved against her, the offence is clear. The prosecution will have to show: 1st, that the persons were insane, and, 2nd, that restraint was imposed. If restraint has been imposed upon persons who are not insane, Mrs. RUTLEY has laid herself open to an action at law by the aggrieved parties.

In the case of the unhappy man SWEETLAND, the point which the jury were called upon to decide was whether the crime had its origin in drunkenness or insanity. The distinction between the two is not always easy, for it is well known and universally admitted that suspicion of others is a very common symptom in delirium tremens. The prisoner was a wild, dissipated character, and had been "on the drink" for three days prior to the murder, and had consumed very nearly a pint of raw gin just before he committed the act. Had he committed suicide instead of murder, a verdict of temporary insanity would have been returned to a certainty; and had he made his will on any of the three days preceding the act, that will would have been set aside to an absolute certainty. Unfortunately he committed the very act which in the case of SALEWSKAL afforded the most unanswerable proof of *insanity*, and a jury have consequently handed him over to the executioner. Supposing we admit that SWEETLAND was drunk and not mad, we have in the case of

MAINWARING a precedent for altering the punishment to one of penal servitude for life; and should he, as a prisoner, afford undoubted evidence of insanity, he could then be removed to an asylum, and be liberated on a ticket of leave should his recovery be fully established. As it is, the sentence imposed upon him seems to have been respited without deciding the question of insanity, in which we are principally interested.

Annotations.

"Ne quid nimis."

THE GROCERS' LICENCE QUESTION.

THE EARL OF ONSLOW did good service on Friday last in the House of Lords by again calling attention to the great question of Grocers' licences. In the course of his remarks his lordship said:—

"Grocers' spirit licences had been largely on the increase. Those licences could be refused only on two statutable grounds—either that the person or the house was not entitled to such a licence. The grocer paid for his licence £28 11s. 2d. a year; while the licensed victualler, with a house valued at £100 a year, now paid £16 10s., and under the change proposed by the Chancellor of the Exchequer would in future pay £30. The number of grocers' licences was likely to increase in consequence of the change. There was an objection to those licences being granted by magistrates because of the invidious position in which these functionaries must be placed if they had two applicants of equal respectability from the same street; but he should like to see power given to the magistrates to say the number of those grocers' licences which were to be granted and to put them up to public tender. In that way the number of grocers selling spirits would be kept down. It was a convenience to many persons to be able to buy spirits in the shops of their grocers, but it had been stated in evidence to the Select Committee that much mischief was caused by the facility for the purchase of spirits which the shops of those licensed grocers afforded to women, and that some of the grocers consented to enter as 'goods' the spirits had by women. Indeed, one gentleman told the Committee that this was so common in Scotland that whenever he found the entry 'goods' in a grocer's account he at once understood it to mean spirits."

The Bishop of Carlisle asked, "Why should not the entering of spirits as 'goods' be treated as a fraud, and why should not the selling of spirits to boys or girls under the age of sixteen be made penal?"

The Earl of Kimberley, on the part of the Government policy of letting this practical question drift, intimated that,

"In his opinion, and in that of the majority of the committee, the evidence given before them completely failed to prove that any appreciable increase of drunkenness could be ascribed to those particular licences. They were licences which were possibly liable to attack on various grounds, but no direct evidence had yet been produced of an immediate connexion between them and the prevalence of drunkenness. He had not found the assertions with regard to alleged increase of drunkenness among women supported by the evidence; and as to grocers' licences, they were only 2000 or 3000 out of a total of 100,000 licences for the sale of intoxicating drinks. He merely made these remarks to show the noble lord that he had not lost his interest in the subject. He did not express any opinions on the subject; he wished to be quite unfettered with regard to any Bill which the Government might think it proper to bring in."

Such a statement of official opinion leaves the question in something worse than a quagmire. The Select Committee began by excluding evidence—in the only practicable shape,—then drew an unwarrantable inference from the supposed absence of evidence! The Government has confounded the whole business by accepting a Report based on proceedings thus faulty.

SANITARY REGULATIONS OF THE AUSTRIAN NAVY.

THE Minister of Marine of the Austro-Hungarian Empire has recently issued a circular to all the seaport and maritime authorities. Several cases of small-pox had occurred on board some merchant ships, and this has incited the Government to formulate more stringent and precise regulations in respect to this disease. The circular in question is written in the Italian and the Illyrian languages, and these are its principal passages:—1. Any sailor or passenger, whether showing evident symptoms of small-pox or only suffering from an eruption of a doubtful character, shall not be allowed to land. 2. Sailors, subjects of the Austro-Hungarian Empire, must be provided with a certificate proving that they have been vaccinated during the previous ten years. 3. If during the journey a case of small-pox should occur, the patient must be at once isolated, placed on special diet, and the use of wines or spirits absolutely forbidden. 4. The excreta, &c., of the patient must be disinfected with sulphate of iron, and then thrown into the sea. 5. The patient, when convalescent, shall not be allowed to associate with the other persons on board till the period of desquamation is terminated. 6. The cabin occupied by the patient must be disinfected according to the system to be subsequently described. 7. When there are several cases of small-pox the entire ship must be disinfected.

With regard to the method of disinfection, many experiments have been made both in Germany and Austria, which have resulted in the recommendation of the following well-known system: Sulphur to the extent of twelve grammes per cubic metre of space to be disinfected is to be burnt in an earthenware basin, placed in the centre of some sand, to prevent all risk of fire. All the linen clothes, &c., are to be hung across the cabin, which is to be hermetically closed for three hours, and then exposed to the strongest possible draught for twelve hours. Then the walls, floor, ceiling, &c., are to be washed with a solution of one kilogramme of lime, or one-half a kilogramme of chloride of zinc per hundred litres of water.

NURSING AND NURSING.

The Council of the Nightingale Fund have issued, along with their report for 1879, reprints of two articles from the *Edinburgh Medical Journal*, one entitled "Nurses and Doctors," written by the Lady Superintendent of Nurses in the Edinburgh Royal Infirmary: the other, on the Nursing in the Edinburgh Infirmary, by Dr. Joseph Bell. We welcome this protest (for such it is) from the Executive of this Fund against that hysterical sentimentalism which is being introduced into the practice of nursing in certain hospitals and institutions, and which is a mischievous caricature of the system of nursing represented by the Nightingale Fund. There is considerable risk of nursing in hospitals being seriously prejudiced by the fussy energy of women, weak and kindly, who have latterly taken to nursing as a sentimental service or mission rather than as a serious duty, but who lack any real knowledge of those domestic arts which form no inconsiderable part of a nurse's calling, and do not possess the aptitude for learning, without which a good nurse is an impossibility. Ladies of this sort are prepared to do anything—except the painful, wearisome details of nursing, and having almost everything to learn, and none of the habits or temper of mind which makes the nurse's duty sit comparatively light upon the person who undertakes it; they hold themselves, after the study of a few books and a superficial acquaintance with the brighter side of hospital life, capable of instructing all. The paper, written by the female Superintendent of the Edinburgh Infirmary, indicates the distinction between nursing as a serious

duty for cultivated women, and nursing as the sentimental, not to say hysterical, outcome of unacknowledged, but not the less real, idleness. The old system of nursing was bad in some of its details, but, as she says, it had its redeeming qualities, and not the least important of these, still insufficiently apprehended, was the fuller apprehension of the wants of the patients and the greater approximation between the feelings of patient and nurse. We question whether, if the matter were carefully looked to, the evils of the old system, such as they were, are not outdone by many of the evils of the "new system," so-called. Who familiar with the class of nurses in question has not been made conscious that the patient has been made to serve the self-beatification of the nurse, and not the occasion for the development and manifestation of the most lovable of the characteristics of womanhood? What hospital surgeon or physician has not, moreover, had anxiety and trouble from the growing tendency among these nurses to profess to be outraged in feeling (heaven save the mark!) by the ordinary and necessary incidents of surgical and medical practice in ward life? The publication, by the Nightingale Fund, of the papers which have been referred to, will serve to make evident to the public, when the question of "a new system of nursing" is under discussion, that a distinction has to be made between one new system and another, and happily a standard of the new system which should be followed is to be found in the wards of St. Thomas's Hospital, and in the work of the Nightingale Fund.

THE VIRGINIAN PRUNE.

Few drugs have a wider repute in the United States, and have failed more completely to gain a position in the practical therapeutics of this country, than the Virginian prune bark. In spite of the recommendations of Dr. Clifford Allbutt and others, it is still almost unknown to the bulk of practitioners. An instructive and fairly complete account of the history and uses of the drug, by Dr. Van der Espi, has recently been published in the Belgian *Journal de Médecine*, and some of the facts there mentioned may be interesting to our readers. The tree grows in all the States of the Union, but it attains the largest size in the southwestern States. Everywhere in the northern States it is reputed one of the most useful of indigenous remedies. According to Proctor, the bark yields a volatile oil, of pale-yellow colour, which has the odour of bitter almonds, and contains hydrocyanic acid in such quantity that two drops will kill a cat in five minutes. The prussic acid does not exist as such in the bark, being formed, as in bitter almonds, by the action of emulsion on amygdaline. It contains also tannic and gallic acid, starch, resin, salts of lime, potash and iron, a fatty matter, woody fibre, and a red colouring matter. These facts have been confirmed by the author of this memoir, and he has further proved that the amygdaline exists in the Virginian prune bark in a crystallisable form. Its quantity is, however, very variable; it is different in each kind of bark; that of the root contains more than that of the trunk, and the latter more than that of the young branches; it varies also with the age of the tree, with the time of year at which it is collected, with the age of the bark, and with the mode in which it is preserved. The contact of moisture causes the emulsion to act upon the amygdaline, and the bark is therefore best preserved in zinc cases, hermetically closed. The red colouring matter he finds to be analogous to the soluble red substance found by Pelletier and Caventou in the chinchona bark.

A gramme of the powdered bark has a taste which is at first astringent and afterwards bitter, and resembles that of prussic acid. It causes a sensation of warmth at the

epigastrium, and appears to have a tonic (or stimulant) action, increasing the general sense of energy. Diminished sensibility, retardation of the pulse, and lowered temperature follow, due, no doubt, to the prussic acid which is formed. Strong doses, taken several times a day, were found to reduce the pulse from 65 to 50. When the dose exceeds three grammes, it causes a sensation of fulness at the stomach, nausea, and diarrhoea. Larger doses cause dangerous symptoms, due to the hydrocyanic acid, which appears to combine with the hæmoglobin of the blood.

The value of this substance in medicine appears to depend chiefly upon the constituent tannin and prussic acid, and it is said to be useful in debility of the digestive organs, general debility, accompanied by local or general irritation, in the convalescence from local inflammations, in acute febrile diseases, and in painful affections of the stomach. It has been recommended in intermittent fever. Tannin has been held in high repute in the treatment of ague (Chancere, Pezzoni), and so also has prussic acid in the form of bitter almonds. The prune bark is much used in America in the treatment of phthisis; it is said to have a marked effect on the pyrexia, on the cough, on the expectoration, and on the night sweating. It has been used by Van der Espi with success in whooping-cough. Hydrocyanic acid is an old remedy in the affection. In this country the bark has been used chiefly in heart disease, and it is said to be of very marked value as a cardiac sedative, most useful in the cases in which digitalis is not well borne. In bronchitis the sedative effect of the prussic acid on the cough, and of the tannin upon the expectoration, is said to be valuable. It has been recommended as an external application to ulcers and as an application to the eye in catarrhal ophthalmia. In the latter Van der Espi asserts that it is much more useful than simple tannin. These are the chief alleged uses of the drug, but the list does not by any means exhaust the class of diseases in which it has been recommended, and which comprehends a large proportion of known maladies. The bark is administered as a powder, in an infusion, a syrup, or a tincture. By evaporating the tincture, an extract is obtained which the Americans call prunin or cerasin, the dose of which is from two to ten grains. Possibly the reason why it has been so little employed in this country is the deterioration of the bark before it reaches us.

SEAMEN'S HOSPITAL SOCIETY.

THE Seamen's Hospital as a charitable institution is unique of its kind. Seamen of all nations not only receive relief from it when sick or otherwise distressed, but are retained within its walls till sufficiently strong to resume the duties of their calling. From the last annual report we are pleased to learn that the finances of the institution are in a flourishing condition. Not only have the subscriptions increased, but the reserve funds now amount to over £120,000. With this fund it is proposed at some future date to build a permanent hospital, the present building being only lent by the Government. With so large a sum in hand, it is to be hoped the Committee will see their way speedily to commence operations, for the building they now occupy is certainly not suited to the requirements of a general hospital. Besides, it is out of the way of the sick sailor. Formerly, when the old *Dreadnought* lay in the river, ships as they passed up to dock dropped their sick as they passed. Since the removal of the institution ashore this is seldom done, and the ship goes on to port and the sick sailor has to be transported back to Greenwich. Practically when once in port it is easier for the sailor to go to the London, Guy's, St. Bartholomew's, and the German hospitals than make a long journey across the river back to Greenwich. There is very little doubt that of late an increasing number of sick sailors, especially those suffering from acute diseases, have found their way to

the wards of the hospitals we have named. At present the Seamen's Hospital is on the wrong side of the river, and should the Committee determine to build they should endeavour to secure a site in the very midst of the docks. The establishment of an out-patient department at the docks will in no way meet the case, as this arrangement will not get over the difficulty of the transportation of acute cases across the river back to Greenwich. The Committee hold a noble sum of money in trust for the sick sailor, and we hope it will not be frittered away. Till, however, they begin to build, they have from the interest of this money an ample sum to aid towards their yearly expenses, and can well afford to allow the current of private charity to flow for a time in directions which urgently require it. It is anomalous for one hospital to be accumulating a prodigious reserve, whilst another, like Charing-cross, has to close some of its wards from lack of funds to provide for its ordinary requirements.

EXPLOSIONS.

THERE can be no question as to the substantial accuracy of the finding in the case of the recent explosion of a mixture of gas and common air in a main near the Tottenham-court-road, to the effect "that the deaths were caused by an explosion, that that explosion was caused by a light being ignorantly placed to a pipe by Hawkes, the gas having been introduced into the new main by some defect in the valve in Howland-street." The jury appended to their verdict a rider, giving it as their opinion that additional care should be taken by the Gas Light and Coke Company in the testing of new mains. Another explosion precisely of the same class, and from a like cause, has occurred at Bilston. It is, as the *Daily Telegraph* in an able leader on the subject points out, a grievance "that we should have gasmen as ignorant in their ways of dealing with gas as the untrained householder. . . . Everybody knows that it is quite safe to light an ordinary burner in a room; so that if any leakage is comparable to the common gas jet no harm will result by applying a burning match to it. Yet in that case the leakage must be an escape under strong pressure. If not, if it be a mere ooze, if the gas has stagnated either in a long pipe with a free opening to the air, or in a confined space to which air gets access, then as the atmosphere and the gas are of different degrees of heaviness a process of diffusion takes place. The gas comes to the surface, and air forces its way behind, where it may remain mixed with the gas in the proportion of one part to fifteen. If in these circumstances a light be applied the surface film burns, and its flame runs back until it ignites the explosive mixture behind—that mixture being the amalgamation of inflammable vapour and air, which has been formed in obedience to the law of diffusion." This is a very fair popular account of the facts, and if it should have the effect of opening the eyes of the gas companies to the nature of the article with which they have to deal—teaching them the rudiments of their business, so that they can educate their servants up to the point which is necessary to public safety,—the *Daily Telegraph* will have done good service. Meanwhile, M. Kæuffer, in the *Annales de la Société Médico-Chirurgicale de Liège*, has a lesson for us, of the medical profession, and for dispensing chemists and the public, which we are glad to be able to reproduce. The facts recited are easily forgotten, and should be kept in memory by prescribers. In some instances it is even possible that they may be unknown. We quote from the *Canadian Journal of Medical Science* :—

"M. Kæuffer has published, in the *Annales de la Société Médico-Chirurgicale de Liège*, an interesting study of pharmaceutical preparations, which in certain cases, often not well marked, may give rise to explosions. Amongst these very numerous substances we will cite only the most important.

The author, for example, while preparing a pomade composed of chloride of lime, flowers of sulphur and other substances, saw small detonations produced, and the entire mass entered into deflagration. Another time, essence of turpentine having been poured into a bottle in which remained some sulphuric acid, the vase burst. These explosions may be produced in many other cases. A German journal reports that in America, one of the most dangerous substances, nitro-glycerine, is found in all the homœopathic pharmacies. The hypophosphites may also be the cause of accidents. In one case, the mixture of hypophosphite of lime, chlorate of potash, and acetate of iron produced a violent detonation, which burned the preparator and put his life in danger. The trituration of the hypophosphite alone may be dangerous when the substance is very pure. The solutions of oxidising bodies in glycerine demand the greatest prudence. Thus, chromic acid in glycerine has been able to give rise to a violent detonation. In this case the solution should be made drop by drop in order to avoid accidents.

"The solution of permanganate of potash in glycerine presents an analogous danger. Pills of oxide of silver have equally been able to determine on the one who carried them a formidable explosion. The iodide of nitrogen, which may be formed in certain circumstances, is also detonating. Now, in America there are frequently seen prescriptions ordering a mixture of tincture of iodine with ammonia, which necessarily form iodide of nitrogen; if the explosion is rarely produced, it is because the trituration is generally made in the presence of water, which prevents this result. In any case, this mixture should only be made in very small quantities. A pharmacien ought then to refuse to fill a prescription for which tincture of iodine is to be mixed with an ammoniacal liniment; he ought also to refuse to make every mixture of chlorate of potash mixed with sulphur and analogous substances. Thus chlorate of potash mixed with tannin is dangerous, and these bodies ought only to be delivered separately, in the case where the physician prescribes them in substance, and not under the form of gargle. A tooth-powder, pointed out by Price, composed of chlorate of potash and cachou, and used with a dry brush, would be capable of producing a detonation in the very mouth of the patient. Price also noted danger from concentrated solutions of permanganate of potash in alcohol and water, which may be filled but never delivered in uncorked bottles; if not, explosion follows infallibly.

"Chlorate of potash with glycerine also constitutes a dangerous mixture. Once a gargle prescribed by one of the most renowned physicians of New York, containing equal parts of chlorate of potash, perchloride of iron and glycerine, exploded with great violence, not in the pharmacy, but in the saddle-bag of the bearer.

"Another time, a similar mixture exploded, only some time after its preparation, under the influence of the rays of the sun. This time the explosion caused the burning of the house. Lately there has been noticed an explosion of a powder containing chlorate of potash and hydrochlorate of morphine."

ROYAL COLLEGE OF SURGEONS.

FROM the annual report of the receipts and expenditure of the College from midsummer-day, 1879, to midsummer-day, 1880, and which has just been published, it appears that the income from all sources amounted to £15,612 17s. 5d., derived principally from fees paid by candidates for the diplomas of the College producing the large sum of £12,683 15s. Rents from chambers adjoining the College and dividends on stock yielded £2527 3s. 1d. Fees paid by members of the College on their election to the Fellowship, and which formerly added so largely to the funds of the College, only produced thirty guineas during the past year. Members of the Council and Court of Examiners paid on their admission as such just 100 guineas. Receipts from Trust Funds amounted to £247 7s. 10d. The annual expenditure amounted to £15,482 19s. 7d. The largest item appears in fees paid to the members of the Council—Courts and Board of Examiners—viz., £6326 18s. Salaries and wages to the large staff of officers and servants in the three departments of museum, library, and office, is not large in £3950 3s. 5d. For taxes, rates, and diploma stamps,

£1348 18s. 6d. was required; the lecturers receiving £144 18s. Museum specimens, &c., £606 11s. 8d. Books for the library, £368 6s. 11d. Notwithstanding these necessarily heavy expenses there appears a balance at the bankers of £384 14s. 7d. The accounts are all carefully examined by a committee of auditors consisting of six members of the Council.

MEDICAL NEWS FROM RUSSIA.

ON the initiation of the Medical Society of Tver, and with the support of the Municipal Council of the Zemstvo, it has been decided to establish a colony for the insane in the vicinity of the city. The colony is to give accommodation to 400 patients, and it is estimated that each patient will cost 632 roubles annually. The municipality have made a grant of 253,615 roubles towards the establishment of the colony, that sum representing 50 per cent. of the presumed total cost.—At the sitting of the Municipal Council of St. Petersburg on the 24th ult., the question of the deficiency of hospital accommodation in the city was debated. The deficiency was estimated at 2000 beds, and it was considered whether these should be provided by temporary hospital buildings or by weeding the hospitals of convalescents and placing them in buildings which might be prepared for them at a less cost than hospital buildings proper. In the end the Council determined to make a grant of 200,000 roubles for temporary hospitals and 30,000 roubles for the establishment of a convalescent institution.

THE DEATH OF MR. TOM TAYLOR.

THE medical profession will think regretfully of the death of Mr. Tom Taylor. He was a man of culture, and outside his work as a dramatist had a claim on the respect of the community. As one of the principal contributors, and in late years the editor, of our facetious contemporary *Punch*, Mr. Tom Taylor was always appreciative of the efforts made by the medical profession to relieve suffering and promote the public good. In his writings for the stage and for the leading satirist of the day and the age, he showed himself ready and anxious to help, instead of sneering at, the cause of public health promotion and the endeavours made in good faith, if not always successfully, by THE LANCET to inaugurate and advance useful sanitary and hygienic reforms. It is only fitting that we should record the regret we feel at having lost so excellent a friend, and in so doing we express the personal respect and regard which a large circle of friends in the medical profession entertain for the deceased gentleman.

THE GOVERNMENT AND THE IRISH FEVER CASES.

THE Report of the medical men sent to the districts where fever prevails is in the hands of the printers, and may be expected daily. Four nurses, too, have been sent down to the cases from the Hardwicke Hospital.

KING'S COLLEGE HOSPITAL will be closed from the 17th inst. until the 19th September (inclusive). Arrangements have been made to transfer the more serious cases to other hospitals. We hear that Professor Lister will remove about twelve of his more urgent cases to a private hospital in Fitzroy-square, so that they may continue under his personal supervision.

THE Medical Council has done one new thing which will require grave consideration at another time. It has passed a Resolution imposing a new examination on medical students, or on students before entering the profession—an examination corresponding to the Preliminary Scientific Examination of the London University.

THE
GENERAL COUNCIL OF MEDICAL
EDUCATION & REGISTRATION.

Session 1880.

Thursday, July 8th.

THE General Medical Council resumed its sittings on Thursday, the 8th inst., Dr. Acland, President, in the chair.

A report was read from the Committee on Ophthalmology and Midwifery with reference to the memorials received from ophthalmic surgeons and from the Obstetrical Society. The report stated that the memorials had been submitted to the licensing bodies, and answers had been received from all of them except the Universities of Cambridge, Durham, and Queen's, in Ireland. It added:—"With reference to ophthalmology, the opinion of the bodies is almost unanimous that, under the present arrangements of their respective examinations, the subject of ophthalmology receives its fair share of attention, and that it would not be desirable either to require attendance on a special course of lectures on ophthalmology as part of the curriculum for a medical student, or to make ophthalmic surgery a distinct subject of examination (separate from surgery) at the pass examination for a licence to practise. The Committee see no reason to dissent from that opinion of the licensing bodies, and they accordingly do not advise the Council to recommend that a special course of study of Ophthalmology, or a distinct examination in that subject, should be required. With reference to the subject of Midwifery, there is considerable difference in the requirements by the different licensing bodies as to the extent of study, some requiring as many as a hundred lectures, and others fifty or fewer, and some requiring as many as twenty cases of labour to be attended, while others do not require more than six. Seeing that the Council have not hitherto deemed it expedient to specify in their Recommendations the exact quantity of study to be certified in any particular subject, the Committee do not advise the Council to follow an exceptional course with regard to Midwifery. With reference both to Ophthalmology and to Obstetric Medicine, it appears to the Committee that if the Council should hereafter have to reconsider the conditions of the medical curriculum as a whole, part of such reconsideration must of course consist in the Council's satisfying itself that each of the several branches of practical study will receive its due share of attention from every candidate who proposes to present himself for examination; and the Committee can at present only suggest that, whenever the time for such general reconsideration may come, it will be well for the Council to refer again to the two memorials which are now reported on."

Dr. HUMPHRY moved that the report be entered on the minutes, and that copies should be sent to the memorialists.

Dr. HAUGHTON objected to dealing with the subject of ophthalmology on the same footing as the important subject of midwifery. He proposed that the latter subject should be at once considered by the Council, and that Dr. Humphry's motion should apply only to the former.

The consideration of the question was postponed till after the adjourned debate on preliminary education.

Dr. BANKS, in resuming the discussion, defended the Queen's University of Ireland from the imputation of neglecting preliminary education, and compared the requirements of that body with those of the Medical Council. He said that the great difficulty of the University had been the deficiency in the middle-class schools in Ireland—a deficiency that would no doubt be remedied by the measure on intermediate education passed by the late Government. He maintained that the University had fulfilled its mission to the utmost of its ability, and endeavoured to raise the standard of general and medical education. He had no doubt that better days were dawning, and that better prepared candidates would be sent up for the matriculation examination. As a proof of the stringency of the examinations of the University, he alluded to the small number of rejections of its student by the Army Board.

Dr. SCOTT ORR vindicated the Faculty of Physicians and Surgeons of Glasgow from the imputation of neglecting preliminary education, and asserted that its examinations were quite abreast of the requirements of the Medical Council.

Dr. PYLE made a similar vindication with reference to the University of Durham.

Dr. ROLLESTON alluded to the defects which had been pointed out in Glasgow, and expressed his regret that the Scotch bodies had opposed the scheme of conjoint examination.

Mr. TURNER complained of the course adopted by Dr. Storrar, and compared his speech to the Commination Service. He explained the nature of the examinations of the Scotch universities. He said there was no entrance examination to the Faculty of Arts in any of the Scotch universities, in which respect they resembled the Oxford and Cambridge Universities; but the Universities of Edinburgh and Glasgow had arranged to bring such an entrance examination into operation next winter. The examinations in general education for medical students, he said, were largely conducted by non-professional examiners, and were fully up to the requirements of the Council. Referring to the system of "remanet" examination, denounced by Dr. Storrar, he said that in Scotland the matriculation certificates of the English universities were accepted as far as they went, but the holders were required to be examined in additional subjects not included in those certificates. He objected to unduly harassing the student in regard to his preliminary education, and approved of the principle of one examining body accepting the certificates of another as far as they went. He opposed the suggestion of Dr. Storrar to refer the question to a Committee. There had been committees enough appointed already, and the time had arrived when the whole question should be considered by the Council itself. The standard ought no doubt to be raised, and then the preparation of students would be proportionately improved. The subjects of examinations, he thought, might be increased. He had a list of subjects which he was prepared to recommend, but this was perhaps not the fitting occasion for bringing it forward.

Mr. SIMON thought that the Council should at once deal with the reports of the Branch Councils, instead of referring to a Committee questions which had again and again been reported upon. He did not object to referring new questions, such as a revision of the system of preliminary examination; but to refer matters already reported upon would only be ridiculous. He thought it would be unwise, in the present provisional position of the Council, to enter upon any large prospective undertakings. They had all been advocating considerable and radical changes in the licensing system; and the constitution of the Council itself had been challenged; and until questions of that kind were settled, prospective resolutions, such as those proposed, would be of little use. For twenty years the Council had recommended that preliminary examinations should not be conducted by the licensing bodies; but the recommendation had not been regarded. He was himself prepared to take a vote upon the subject whether such examinations should be considered satisfactory for the purposes of the Medical Act. The question should be settled by the Council, and not referred to a Committee.

Dr. WOOD deplored the speech of Mr. Simon, which he said was tantamount to a proposal to the Council to abdicate its functions and declare itself incompetent. He agreed that it was useless to refer the question under consideration to a Committee. He denied the statement of Dr. Storrar that nothing had been done in regard to the improvement of preliminary education. The recommendations of the Council had been largely adopted by the licensing bodies. He admitted that they declined to adopt the recommendation to abandon their preliminary examinations, and they intended still to decline to follow that recommendation. The Council had its remedy, and could take the bodies, if it desired, before the Privy Council. The present Government had stated that it was not at present prepared to legislate; and it appeared to him, therefore, that the present was a breathing time for the Council, in which it could undertake the reforms which it considered necessary. He protested against waiting for possible legislation, which might not come till the Greek kalends. A waiting policy would only be throwing water on the licensing bodies in their efforts to meet the views of the Council in regard to education and examination. A number of important proposals were upon the programme for the present session; and he hoped those

questions would be considered in detail by the Council. With regard to the proposal to take away from the corporations the right to conduct preliminary examinations, he maintained that the Council had no more right to take away that power than it had to take away the power of conducting professional examinations. The examinations were conducted by eminent and competent men, and they were not a sham but a reality. In the body which he represented there had been at a recent examination 101 students examined in English, and of these 82 passed and 19 were rejected. In Latin, of 134 examined, 78 passed and 58 were rejected. In arithmetic, of 93 examined, 52 passed and 41 were rejected. In algebra, of 112 examined, 69 passed and 43 were rejected. In Euclid, of 125 examined, 99 passed and 26 were rejected. In mechanics, of 66 examined, 40 passed and 26 were rejected. In French, of 87 examined, 52 passed and 35 were rejected. As to the system of "remanets," he contended that it was not open to the objections brought against it. He saw no reason why a student who had passed a creditable examination in Latin, French, and arithmetic, and failed in algebra and Euclid, should not be allowed within a reasonable time to come up again for the latter subjects. He knew it was contrary to the system adopted in England, but they claimed in Scotland to be allowed to judge for themselves on that point and act according to their own genius. No doubt in some of their professional examinations there was a great deficiency in regard to grammar and spelling; but how did they know that some of the students had not been examined by the great universities? In some cases it had been proved that such was actually the case. He had no doubt that many improvements might be made, but he asked the Council to pause before raising the standard too high, and thus unduly to limit the number of general practitioners required by the country.

Mr. TEALE moved as an amendment, "That a Committee be appointed to draw up a series of propositions to be submitted to the Council, which shall embody the various motions on the programme in reference to preliminary examinations, and such other questions on the same subject as it shall seem desirable to such Committee to submit to the vote of the Council; this report to be brought up at the opening of the meeting on Friday, in order that a distinct vote may be passed upon them during the present session; and that the Committee consist of the following members:—Mr. Teale (chairman), Dr. Humphry, Dr. Storrar, Dr. A. Wood, Mr. Turner, Dr. Leet, Rev. Dr. Haughton, and Dr. Fergus." He objected to a waiting policy, as recommended by Mr. Simon, as it was very doubtful whether the subject would be taken up early by the Government; and it was very desirable to arrive at some definite conclusions on certain points. Many proposals had been made, and it would be a saving of time if a Committee were appointed to formulate the subjects for the consideration of the Council.

Dr. A. WOOD seconded the amendment.

Dr. HAUGHTON objected to the appointment of a Committee as proposed by Mr. Teale, believing that the desired result would not be obtained in time for discussion by the Council during the present session.

Dr. ROLLESTON also opposed the amendment, and spoke in favour of Dr. Storrar's resolution.

Dr. STORRAR said he was in no way opposed to the proposal of Mr. Teale, and was willing to adopt it instead of his own motion.

Dr. FERGUS urged the importance of the Council having some check upon preliminary examinations.

Dr. A. SMITH suggested that the Council should resolve itself into a Committee to consider the question.

Dr. STORRAR then replied, and asked permission to withdraw his motion in favour of that proposed by Mr. Teale.

Dr. HAUGHTON objected to the withdrawal of Dr. Storrar's motion, and it was accordingly allowed to stand.

Mr. Teale's amendment was then put and carried, and was also adopted as a substantive motion. Dr. Storrar's motion therefore fell to the ground.

On the motion of Dr. A. SMITH, seconded by Dr. QUAIN, the standing orders of the Council, as revised by the Committee appointed for the purpose, were received and adopted.

An application for registration from Mr. John Dwyer having been referred to the Council by the Executive Committee, with the recommendation that the evidence produced of his having acted as surgeon in the public service prior to 1858 be accepted as a qualification for registration, the application was granted.

A similar application was received, and granted, from Dr.

William Wotherspoon Ireland, who had acted as assistant-surgeon in the East India Company's Service prior to 1858.

A certificate was read of the conviction of George Frederick Totter (M.R.C.S. Eng. 1867, L.R.C.P. Lond. 1867) for manslaughter in January last at the Leeds assizes. The offence was that of riding over a boy, who died from the effects of the shock. The prisoner, it appeared, had been fined on several occasions for furious driving and once for drunkenness. The Council deliberated on the case in private, and resolved that it was not deemed expedient to remove the prisoner's name from the Register.

The Council then adjourned.

Friday, July 9th.

The Council reassembled under the presidency of Dr. Acland.

OPHTHALMOLOGY AND MIDWIFERY.

Dr. HUMPHRY moved the adoption of the Report of the Committee on Ophthalmology and Midwifery.

Dr. HAUGHTON objected to the reception of the report. It would be wrong, he said, to allow the arrangements of the licensing bodies for the teaching of midwifery to continue for another year in their present disgraceful condition, but he had no objection to postpone the consideration of ophthalmology, or any of the other "ologies" pressing for recognition. It often happened that a young man was appointed to a regiment or to a ship where he had to deal with midwifery cases, of which he was unable to take charge. The University of Dublin, in the view of such contingencies, had required from its licentiates a six months' course of lectures on midwifery, and a six months' attendance on a maternity, including thirty cases personally attended. Ophthalmology was an ornamental subject that was not of the pressing importance of midwifery, and its consideration might well be postponed. He proposed that the Council should recommend the plan adopted by the University of Dublin.

Mr. MACNAMARA seconded the proposal, and said that the College of Surgeons in Ireland was alive to the importance of the subject of midwifery, in which it had a distinct examination, and it did not allow a student to come up for a surgical licence until he had brought forward satisfactory evidence that he had been engaged in the study of midwifery. As to the number of cases of labour to be attended, that was a matter which should be left to the Branch Councils, but some amount of attendance should always be required. The Committee declined to recommend any exceptional dealing with midwifery; but he contended that there should be a special examination in a subject of such serious importance.

Dr. A. WOOD said that the subject was everywhere made part of the medical curriculum. It was considered by them all as a most important subject. The Council, however, ought not to lay down minute details as to the number of lectures or labour cases that should be attended, which might well be left to the bodies themselves. In Scotland it would be impossible to send each student to thirty cases of labour. Before the requisite number of accouchements could be provided it would be necessary to import a colony of Irishwomen.

Dr. A. SMITH thought that the Council should take care that every practitioner should be well qualified in midwifery; but the details of the subject might be left to the licensing bodies.

Dr. QUAIN said that midwifery was already one of the subjects a knowledge of which was required by the Council; and he did not know that anything further was needed.

Mr. SIMON said that the rule had hitherto been to recommend certain subjects of study, but not to prescribe the details of the lectures, &c.; and that rule had been followed in reference to midwifery. He thought the rule a safe one, and hoped it would be adopted by the Council. The Committee had not, as suggested by Dr. Haughton, proposed to deal with midwifery and ophthalmology as on the same footing, though it had dealt with them in the same report.

Dr. BANKS objected to laying down details of study and examination in midwifery, as proposed in Dr. Haughton's resolution.

Dr. HAUGHTON said he should be willing to modify his amendment by stating that the Council recommended a course of lectures in midwifery and a course of instruction in practical midwifery, without stating the number of attendances required.

Dr. HUMPHRY, in reply, said that the Committee had thrown no slur upon the study of midwifery, and had expressed no opinion as to the comparative value of that subject and of ophthalmology. The only question was, whether they were to deal exceptionally with midwifery, treating it in a different way from all other subjects. No such legislation as that proposed by Dr. Haughton had taken place in reference to anatomy, surgery, or other subjects, and he saw no reason for it in reference to midwifery.

The amendment was then negatived, and the motion for the adoption of the report was put and carried.

GREEK.

Dr. LEET proposed, "That on and after the 1st of January next Greek be included among the compulsory subjects of the preliminary examination for medical students." He stated that the Apothecaries' Hall in Ireland included Greek among its subjects of preliminary examination for medical students, and it did not feel disposed to lower its standard. Dr. Leet urged the importance of a knowledge of Greek in the way of general culture, and as affording a clue to the meaning of scientific terms; and cited the opinions of several eminent educationalists to that effect. He called attention to the fact that many years ago the Council had adopted Greek as a compulsory subject, but had never given effect to its resolution.

Mr. MACNAMARA seconded the motion.

Dr. A. SMITH said that Greek was now, according to the standing orders, an optional subject. He thought it should be compulsory; but he objected to the inadequate examination to which some students were subjected: it was no guarantee that a useful amount of knowledge of the language had been acquired.

Dr. STORRAR said he had fought the battle of Greek at the Council as long as he could, but he finally gave it up. Modern education was increasingly disregarding Greek, and he believed that before long the language would only be cultivated by a few scholars for its own sake. The London University gave its degrees in Science, Medicine, and Law, without a knowledge of Greek; and it was considered that German gave the student many of the educational advantages supposed to be limited to the older languages. Considering the limited time that could be devoted to preliminary education, he should vote against Dr. Leet's proposal.

Mr. SIMON, while acknowledging the great importance of Greek, believed that if it were made compulsory the supply of medical men for the public would be unduly limited.

Dr. ROLLESTON regretted that he could not vote for making Greek compulsory, which would, he said, exclude a number of boys attending the modern public schools, where Greek was largely superseded by modern languages and science.

Dr. FERGUS cited the opinions of several authorities, including Professor Huxley, against rendering Greek compulsory, and urged that there were other subjects, having a more direct bearing upon medicine, that would equally exercise the student's mental powers.

Dr. HAUGHTON, in supporting Dr. Leet's motion, said that from time immemorial law, physic, and divinity had stood side by side; but the proposal to lower the educational standard of medical men by declaring Greek unnecessary was the first step to placing them in an inferior position. He was aware that many of the Greek examinations of medical students were of a very unsatisfactory character; but the Council could always raise the standard. In the Apothecaries' Hall in Ireland the Greek examination was of a very high-class. Nothing was so distressing as to try and teach an uncultivated brute of a student who had never learned Greek, and he hoped that the Council would declare the subject compulsory.

Dr. BANKS supported the motion, and said if Greek were excluded the profession would enter on a downward course.

Dr. PETTIGREW said it was not proposed to exclude Greek, but only to allow it to remain, as he thought it ought to be, an optional subject. He believed that there were many other subjects equally valuable as instruments of intellectual training; while there were some students possessing excellent talents, and worthy to enter the profession, to whom the study of languages was a matter of great difficulty.

Dr. HUMPHRY regretted the loss of Greek, but thought that they must bend before the wind. A large number of schoolmasters had reported to the University in Cambridge in favour of giving up Greek as a compulsory subject,

adding that many of the boys were prevented by its retention from entering the University. The subject was accordingly no longer compulsorily required; and if that were the case at the University, it could hardly be contended that it should not be the case with the medical profession. If the standard were too high, there was a great danger that the number of persons entering the profession would be greatly reduced, to the disadvantage of the public.

Dr. A. WOOD reminded the Council that they were legislating for a minimum; and if they erected a barrier which it was very difficult to pass, a great evil would be inflicted upon the community.

Sir W. GULL said it was not honest to require Greek of ordinary medical practitioners. Such knowledge of Greek as the majority of medical students would acquire was nothing but a sham. He did not desire to depreciate scholarship; he wanted Greek for his idle hours as an amusement, but he did not require it for the practice of his profession. He ridiculed the notion of employing a few well-known passages in the Greek New Testament as a test of the student's knowledge of the language.

Sir JAMES PAGET said he agreed with Mr. Simon that the question in this case was what was the least amount of knowledge which a man must possess in order to be a safe practitioner. To say that a man could not acquire enough knowledge to allow him to begin to learn medicine unless he knew Greek was somewhat startling. He had a profound respect for a knowledge of Greek, but only for that which might fairly be called knowledge which would affect the whole of a man's life, or the whole of his mental character. But it would be absurd to suppose that that kind of knowledge could be possessed by all medical students. All that could be expected would be but a smattering, which would vanish in a year or two of serious work in the profession. It might be said that all the other subjects were in the same position, but though a man might come to the study of medicine with only a very elementary knowledge of mechanics or chemistry, that knowledge must almost of necessity grow with every step he took in the profession. That was not so with regard to Greek. Most persons must have noticed in reading medical literature that men often covered very bad English by the use of Greek words, which were ill understood and badly expressed. No doubt it was true that the derivation of English words was frequently taught in schools, but that method might give utterly false explanations. Such words as "asphyxia" and "hypertrophy" would be wrongly explained by their derivations. Much of the discussion seemed to proceed on the supposition that it was proposed to give up Greek, but that language was only to be made optional. He hoped that the Council would not declare that no man could be deemed fit to begin the study of medicine unless he possessed a knowledge of Greek.

The PRESIDENT said when this subject was first discussed in 1866, he had the honour of representing the University of Oxford, and therefore he thought it his duty to consult some of the skilled scholars connected with that University, among others Mr. Goldwin Smith and Dr. Temple, the then Head Master of Rugby. They all agreed in saying that whatever was done should be done thoroughly. It would lower the literary character of the profession to require the mere minimum. To make Greek compulsory would be to reverse the policy of the Council. It was true that it was at one time intended to enforce it after a certain date, but before that time arrived, the Council reconsidered its decision, and decided that it should not be made compulsory.

The motion was put and lost, the numbers being, for it 4; against 17.

Dr. HAUGHTON then proposed: "The General Medical Council being of opinion that the existing Preliminary Examination in Arts is unsatisfactory and insufficient, propose to replace it by the following Examinations:—(1) An Examination, previous to Registration, in the following subjects only:—(a) English; (b) Arithmetic; (c) Latin; (d) Elements of Geometry; (e) Elements of Algebra. (2) An Examination, to be passed not later than at the end of the first year of professional study, in the following subjects:—(a) Greek; (b) Elements of Mechanics. (3) An Examination, to be passed not later than at the end of the second year of professional study, in the following subjects:—(a) French or German; (b) Elements of Hydrostatics and Optics." He said he had been long satisfied that the preliminary arts examination was overloaded, and the consequence of its being so, and of there being seventy-two bodies for conducting it, was that the examination was becoming a farce. He there-

fore thought the Council should lay down a definite regulation. He would like to see more attention paid to handwriting and spelling. The resolution passed in July last year distinctly recognised the principle on which he had founded the latter part of his resolution.

Dr. LEET seconded the motion.

Dr. ROLLESTON objected to it on the ground of its multiplicity. He particularly objected to the suggestion to postpone a part of the preliminary examination till after the student had commenced his professional studies. He submitted as an amendment: "That the treble examination proposed by Dr. Haughton is in principle inadmissible."

The amendment was seconded by Mr. Simon, and supported by Dr. Pettigrew. On being put to the vote, the amendment was carried by a large majority, and subsequently was agreed to as a substantive motion.

Mr. TURNER moved: "That the Preliminary Examination should be raised to the following minimum standard—(a) English to include literature, history, grammar, composition. (b) One ancient language, either Latin or Greek. (c) One modern language, either French or German. (d) Arithmetic, including vulgar and decimal fractions. (e) Elements of mathematics, comprising algebra, including simple equations, geometry, first three books of Euclid or the subjects thereof. (f) Elements of mechanical philosophy, comprising statics, dynamics, hydrostatics, and optics; it being understood that the examination in this branch may be passed either as preliminary or as part of the first professional examination." After pointing out the differences between his proposal and the present regulations, he moved the adjournment of the debate; and the Council shortly afterwards adjourned.

Saturday, July 10th.

The Council reassembled under the presidency of Dr. Acland.

The Council went into Committee on Mr. Turner's motion with reference to preliminary examination.

Dr. HUMPHRY desired to make an explanation with reference to an agenda on the programme of the day. It would be remembered, he said, that a resolution had been passed by the Council in July, 1879: "That the subject of 'Elementary Mechanics of Solids and Fluids'—meaning thereby Mechanics, Hydrostatics, Pneumatics, and Hydraulics—be no longer recommended by the Council as an optional subject of preliminary education, but be recommended as one of the subjects 'without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered,' it being understood that the examination in this branch of knowledge may be passed either as preliminary or as first professional; and that it be referred to the Executive Committee to amend to this effect sub-Section 6 of Section 4, and sub-Section 1 of Section 23, of the edition for 1879 of the Council's standing *Recommendations*." Various bodies had modified their examinations in accordance with that resolution, but scarcely any examination had been instituted in hydrostatics, hydraulics, &c. One of the difficulties that had been mentioned was that if that class of subjects were made compulsory, one other language would be also made compulsory, which the Executive Committee felt was not the intention of the Council. It appeared that the intention of the Council could not be carried out in the way desired. The subjects in question did not form part of the preliminary examinations of the great examining bodies recognised by the Council, and under all the circumstances the Executive Committee had resolved:—"That the Executive Committee, having fully considered this resolution in all its bearings, finds that there are such difficulties connected with carrying it into effect, that it deems it right to refer it back to the General Council for reconsideration." The Council, he thought, ought to be cautious in prescribing additional subjects for the preliminary examinations. The great educational bodies would not modify their examinations in accordance with the wishes of the Council if changes were frequently made; and unless some great object were to be obtained, the Council should hesitate before making alterations.

Mr. SIMON thought that the Executive Committee had been outstepping its functions in not giving effect to the resolutions of the Council. Dr. Humphry's speech would have been appropriate enough last year when the subject was brought before the Council, but it was inappropriate

now. But that the general question of preliminary education was about to come before the Council, on Mr. Turner's motion, he should have felt it his duty to propose a vote of censure on the Executive Committee.

Mr. TURNER moved, "That the preliminary examination be raised to the following standard:—(a) English Language, including literature, history, grammar, and composition. (b) One Ancient Language, either Latin or Greek. (c) One Modern Language, either French or German. (d) Elements of Mathematics, comprising arithmetic, including vulgar and decimal fractions; Algebra, including simple equations; Geometry, including the first three books of Euclid or the subjects thereof. (e) Elementary Mechanics of Solids and Fluids, it being understood that the examination in this branch may be passed either as preliminary or previous to the first professional examination." He said it was not proposed to bring these subjects into the examinations at once, as that would be hardly fair to the students who had commenced their studies. It might be desirable that there should be a year's or two years' grace. He proposed to make distinct motions in reference to each of the subjects, and would first propose that an examination in the English language form part of the preliminary examination.

Sir JAMES PAGET seconded the motion.

Mr. ROLLESTON thought that the question should be referred to a committee, which could discuss it fully and with advantage before the next session of the Council.

Dr. A. WOOD thought it would be absurd to expect a knowledge of English literature from a lad sixteen or seventeen. He objected to making the changes proposed by Mr. Turner, believing that the present regulations were quite sufficient.

Dr. HAUGHTON seconded the amendment.

Mr. TURNER suggested that it might be convenient, for the sake of discussion, to strike out the word "language," and he would simply propose that there should be an examination in "English."

This was unanimously adopted.

Mr. TURNER then proposed: "That the examination in English embrace language, composition, and grammar, and that the General Medical Council will not consider any examination in English sufficient that does not fully test the ability of the candidate; (a) to write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (b) to write a portion of an author to dictation; (c) to explain the grammatical construction of one or two sentences; (d) to point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature; and (e) to give the derivation and definition of a few English words in common use; also (f) that a knowledge of at least two of following subjects be required:—English literature, history, modern geography."

Dr. ROLLESTON seconded the motion.

Sir W. GULL ridiculed the proposal and said it would be better to allow the regulations to remain as they stood.

Dr. A. WOOD said he believed the proposed legislation would only work mischief, and he proposed as an amendment: "That the examination in the English language be such as is now provided for in the 'Recommendations' of the Council, except that the last two lines of the footnote to p. 8 of the last edition of the 'Recommendations' be in future omitted."

Dr. HAUGHTON seconded the amendment, and objected to the introduction of literature and history, as subjects of too wide and vague a character for the preliminary examinations of the students.

Dr. ROLLESTON objected to the omission of literature, and dreaded lest medical men should not be able to hold their own with other classes of society. There were excellent text-books on literature which could be easily studied and mastered, and which would give the required information to the students.

Sir W. GULL supported Dr. Wood's amendment.

Mr. TEALE also supported the amendment.

Dr. HALDANE thought that an elementary knowledge of English literature, history, and geography should be compulsory. Ignorance on such subjects was absolutely disgraceful to the profession.

Sir JAMES PAGET said the Council was bound to make the best use of the improvements that had taken place of late years in general education. To say that more English should not now be required than was required fifteen or twenty years ago, seemed to him unreasonable. He thought

that the proposed change was desirable, supposing it to come in force two or three years hence. Of course the subject of literature would not take an unlimited range; a certain definite range could be prescribed, as in the case of many other subjects.

Mr. SIMON thought that instead of prescribing additional subjects, the examinations in existing subjects should be more complete. The student would almost necessarily take up the subjects of literature, history, and geography; and it was most desirable that he should do so; but he did not see his way to making the subjects compulsory. It would be an immense advantage if every student passed an examination in Shakspeare, but it could not be considered essential.

Mr. TURNER said he was greatly disappointed at a proposal being made and supported to allow things to remain as they were, notwithstanding the greatly improved means of education possessed by students at the present day. There was not, he supposed, a school in the country where history and geography were not taught, and he could not understand the objection to include those subjects in the preliminary education of medical students. The objection really meant that the Council was not to advance with the times, and the Council would be covered with ridicule if it gave effect to that view.

Sir W. GULL said the great error of the present day was the want of thoroughness. He repudiated the notion that he did not wish the Council to advance with the times, but he opposed Mr. Turner's proposal.

After some remarks from Dr. A. Wood,

Dr. ROLLESTON referred to the educational requirements of German medical students, and urged the necessity of insisting on literary culture for medical practitioners if they were not to occupy an inferior position in society.

Sir JAMES PAGET said that the College of Surgeons examined in two out of the three proposed subjects, and low as the examination was it had the effect of excluding two-fifths of the students. He thought that the Council was bound to do its best to encourage an enlargement of education in all the schools, and to work constantly with them.

Dr. PITMAN hoped that the present regulations would be amended. As far back as 1867 the Council had adopted the report of a Committee, which urged the necessity of literary and scientific education; and attention had recently been drawn to complaints that had been made by the licensing bodies with regard to the insufficiency of general education among the candidates presenting themselves. In the face of those facts he thought it strange that it should now be proposed to allow the present regulations to remain unaltered.

Mr. MACNAMARA pointed out that the subject of history would be difficult to deal with in Ireland, owing to the prevalence of sectarian prejudices.

Dr. BANKS thought that the subjects under consideration should be compulsory, and he did not regard as serious the objections stated by Mr. Macnamara.

Mr. TURNER said he was willing to modify his motion by requiring students to pass in two out of the three subjects.

Dr. A. WOOD objected to any change being made in the motion.

Dr. HUMPHRY said if Mr. Turner's proposal were adopted the examinations, which did not include the subjects in question, would not be accepted, and that would be a most serious result. He doubted the possibility of carrying out the proposal.

The amendment was then put; the votes were—for, 12; against, 8; majority, 4. On the amendment being put as a substantive motion,

Dr. HAUGHTON moved, as an amendment, that students should also be required to pass either in modern geography or English history. He was glad, he said, that the "misty bugbear" of English literature was removed out of the way. He agreed with Mr. Macnamara that many Irish students would decline to take up English history, but they would not object to geography.

Mr. MACNAMARA seconded the amendment.

Dr. WOOD pointed out that Dr. Haughton's proposal was not an amendment, and should be submitted as a distinct motion.

After some discussion on this point of order, Dr. Haughton's proposal was put as a substantive motion.

Dr. ROLLESTON proposed as an amendment that the

student should have the option of passing in literature, history, or geography.

Mr. SIMON admitted the extreme value of the subjects in question, but would rather trust for them to the stimulus of social circumstances than to any compulsion.

Mr. TURNER thought that candidates should be specially encouraged to cultivate literature, and he therefore seconded Dr. Rolleston's proposal.

Dr. A. WOOD opposed the motion, and alluded to the numerous subjects required by the Council, asking it not to lay too heavy a burden upon the student.

Dr. HUMPHRY asked the Council to pause before adding fresh subjects of examination, which, he said, would be likely to lead to cramming and superficiality, which were the great defects of modern education. He did not think that the optional system was a good one, and would prefer that definite subjects should be prescribed. It should be remembered that at present examinations the rejections were very numerous. If more subjects were added the standard in the others would necessarily be lowered. He denied the utility of text-books on literature, which, he believed, would rather give a student a dislike to the subject, than prove an incentive to its study.

Mr. MACNAMARA hoped that Dr. Rolleston would not persist in his amendment.

Sir W. GULL ridiculed the notion of the Council discussing the question whether a medical student should be examined in such a subject as geography.

Sir JAMES PAGET asked in what way a student could be better tested than by ascertaining whether he had been able to learn the subjects that had been set before him at school.

Dr. QUAIN urged the importance of a good preliminary examination, and mentioned that at an examination at the College of Surgeons a student, when asked what was the principal event in the reign of King John, replied, "The ship *Magna Charta* was lost off the Wash."

The amendment was then put, and the numbers were—for, 10, against, 11. It was accordingly lost; and the original motion was put and carried.

Mr. TURNER then moved the adoption of the next subject: "One ancient language—either Latin or Greek."

Dr. HAUGHTON said he had an important amendment to move to that resolution.

Mr. TURNER: What! Is there to be no ancient language?

Dr. HAUGHTON: No. I am going to ask the Council to follow out its resolution to its logical conclusions; and I shall propose: "That in the opinion of the Council the English language is the only language absolutely necessary for the Preliminary Arts Examination in Great Britain and Ireland." There must be no Greek sham, no Latin sham, no French sham, no German sham. You have opened up a dangerous precedent.

As the hour for adjournment had nearly arrived, it was resolved to postpone the debate on Preliminary Examination.

The Council then resumed; and on the motion of Dr. Quain, seconded by Mr. Simon, adopted the following financial report:—

The Finance Committee begs to report that the income of the General and Branch Councils for the year ending January 5th, 1880, has been £6381 17s. 9d., an amount which exceeds the income of the year 1879 by £175 4s. 2d. The expenditure during the year 1879 has been £5420 7s. 9d., which is less in amount than the expenditure of the preceding year by £902 7s. 7d. The Committee has therefore the satisfaction of reporting to the Council that, as the result of this increase of income and diminution of expenditure, the actual income has exceeded the expenditure by the sum of £961 10s. Of the tables annexed to this Report, Table (B) indicates the increase or decrease in the several items of expenditure which has taken place during the years 1877, 1878, 1879 respectively. Comparing the items of expenditure of the year 1879 with those of 1878, it will be seen, first, with reference to the items of increased expenditure, that they amount altogether to the sum of £381 4s. 1d., consisting of £23 10s., the cost of improvements in the printing of the Medical Register, and £202 2s. additional for house expenses, due chiefly to the cost of painting and decorating the Council-room. Comparing the items of decrease of expenditure during the years 1879 and 1878 respectively, it will be seen that the principal items of diminished expenditure are in the fees paid to members of the General Council—viz., £660 6s. 6d., and to the Executive Committee £144 18s. There is also a decrease in the cost of printing to the amount of £175 13s. 1d. It will be further noticed that there is a decrease in the items of law expenses, advertisements, &c., amounting to £151 2s. 6d. Table (C) shows the average income and expenditure of the General and Branch Council during the last seven years. It will be seen that the average excess of expenditure over income is £131. The same table shows, however, as already stated, that the income of the year exceeds the expenditure by the sum of £961 10s.

DENTAL FINANCE.—Reference must be made to table (D), which shows the receipts and expenditure of the Dental Registration Fund for the year ending January 5th, 1880. It will be seen that there remained then to the account of the Dental Fund a sum of £7253 17s. 8d. of New Three Per Cent. Stock, and of £3665 13s. 4d. in the Bank of England.

The treasurers have informed the Committee that of this latter sum £2000 has since been invested in the purchase of £2027 17s. 7d. New Three Per Cent. Stock. By request from the Committee, the Registrar has prepared the following approximate estimate of the probable future annual income and expenditure of the Dental Fund:—

ESTIMATED INCOME.		ESTIMATED EXPENDITURE.	
	£ s. d.		£ s. d.
Dividends	274 0 0	Proportion of General Council's Fees	306 0 0
Fees (at present rate)	250 0 0	Fees for Executive and Dental Committees	105 0 0
Total income	524 0 0	Proportion of General Expenses	452 0 0
Deficiency	755 0 0	Printing	290 0 0
		Law Expenses	16 0 0
		Miscellaneous	80 0 0
	£1279 0 0		£1279 0 0

This table shows a probable future excess of expenditure over income of about £750, which, of course, must be met by drafts on the invested capital.

The Council then adjourned.

Monday, July 12th.

At the meeting of the Council to-day,

Dr. HAUGHTON brought forward his amendment to Mr. Turner's motion on Saturday. He contended that the Council had nothing to do with the higher education of medical practitioners, and that a knowledge of Greek, Latin, French, or German was not necessary for the man who had to learn Chemistry, Physics, Medicine, Surgery, and Midwifery in such a way as to be a safe practitioner in the humble position to which he might be called. He therefore proposed, "That the English language is not absolutely necessary for the minimum preliminary examination." He did not know that Hippocrates spoke any other language than Greek, and he maintained that the only language absolutely necessary to the medical practitioner was that of the people among whom he practised. If Mr. Turner's motion were carried an injustice would be done to the students who were preparing themselves in Greek, which was largely taken up in Ireland. Of the 3218 students who went up for the intermediate examination in Ireland under the Act of last session 1209 went up in Greek, 2120 in Latin, 1602 in French, and 121 in German. Greek and Latin, he contended, ought to go together, and it would be a great hardship to students if Mr. Turner's proposal to dissociate them were adopted. If Greek were abandoned, Latin ought not to be retained. He denied that Latin formed any considerable part of the English language, although attempts had been made by Milton and others to latinise the tongue. The language of Swift, Fielding, Smollet, and John Bright, the language of the people, was connected not with Latin, but with the Romance languages and Anglo-Saxon. As to the writing of prescriptions in Latin, God forbid that he should degrade the language of Cicero and Horace by calling medical prescriptions Latin! How many medical men could parse a prescription? The whole thing was a mere *hocus pocus*, and an imposition upon the public—an attempt to hide from every one but the apothecary and the doctor what the unfortunate patient was taking.

Dr. HALDANE, in seconding the amendment, said that Latin, as taught to the majority of students, was of little or no good in the way of mental training; nor could it be said to be a language which would be of any great advantage to the ordinary medical practitioner in his professional career. At the final examinations what little Latin had been learned was often forgotten; for when the students were required to write a Latin prescription without contractions, the ignorance displayed in doing so was simply deplorable. The rank and file of medical men were not now expected to be classical scholars.

Dr. ROLLESTON cited the evidence given by Sir R. Christison before the Royal Commission, in which he stated that he knew no more admirable training for the youthful mind than the study of Greek and Latin. He protested against cutting away the common ground and culture that linked together all the learned professions.

Sir W. GULL said that it was not for the Council to lay down special subjects for preliminary examination, but to look to the school training of the day and simply demand such a test as would be prescribed by intelligent schoolmasters.

Dr. BANKS supported Mr. Turner's motion, and said he should deeply regret the omission of Latin from the preliminary examinations of medical students. Every boy in Ireland learned Greek and Latin at school.

The amendment was then put, and negatived, there being only three votes in its favour.

Mr. MACNAMARA then moved another amendment to Mr. Turner's motion, "That the present recommendations of the Council with regard to Greek, Latin, French, and German, do stand." He said that all students in Ireland learned Latin and Greek, and if neither of those languages was accepted instead of a modern language, great injustice would be done to those students.

It was ruled that the amendment was not then in order, and it was postponed.

Mr. Turner's motion in favour of "one ancient language" was adopted.

Mr. TURNER then moved, "That the candidate may select Latin or Greek, and that the examination shall include translation and grammar."

Dr. A. WOOD objected to giving the student an alternative. It would, he said, be a retrograde movement if Latin were not to be made imperative. It was the best mental trainer ever devised, and it would be a disgrace if it were not rendered compulsory. He should be ashamed to go home to Edinburgh and say that Latin was no longer regarded as a necessity to the medical student. He moved as an amendment that, as at present, there should be an examination in Latin, including composition and grammar.

Dr. STORRAR seconded the amendment.

Dr. ROLLESTON urged the importance of giving the widest scope to spontaneity, and supported Mr. Turner's proposal to give the student an option between Latin and Greek.

Mr. SIMON was also in favour of giving the student a choice between the two languages. The systematic study of any language was a good mental training, and the same might be said of the study of scientific subjects.

Dr. HUMPHRY was in favour of a more liberal view as to the basis of education, and therefore supported Mr. Turner's motion. The time would probably come when the Council would not be able to demand either Latin or Greek as compulsory.

Dr. QUAIN contended that Latin was an essential portion of medical education, and supported the amendment.

The amendment was then put, and the votes were—for, 11; against 11.

The PRESIDENT declared that, there being an equality of votes the amendment was not carried. On the names being taken down, however, it appeared that there were 12 for the amendment, and 11 against. It was accordingly declared carried.

MODERN LANGUAGES.

Mr. TURNER moved: "That an examination in one modern European language form part of the preliminary examination." He said that at present French and German were merely optional, but he thought the time had now come when one modern language should be regarded as an essential part of the preliminary examination. There could be no doubt that it was of great importance to enable a practitioner to become acquainted with what was going on in the science and practice of medicine in foreign countries. The report on the condition of the Scotch universities was very decided on this point. It had been suggested to him that if the principle were approved they should draw the limit at the two languages he had spoken of. At present no country in Europe was more actively engaged in scientific medical work than Italy. Dutch was also a very important language in its scientific aspects, and the option might be extended to that. The same thing might be said of the Scandinavian languages. The schools from which the students came usually taught French, and Dr. Haughton had showed that out of 3218 candidates in Ireland no fewer than 1602 were willing to present themselves for examination in French. The experience at the University of Edinburgh was that whilst very few went in for German yet most of those who did passed.

The motion was seconded by Dr. Banks.

Dr. HAUGHTON said the difficulty he found in voting for the motion was that he conceived the Council was drifting into a possibility of conflict with the higher educational bodies. No one could accuse the University of Dublin of a desire to lower the standard, for with the single exception of Oxford they were the only university in the United Kingdom that required a degree in arts as a preliminary to a degree in medicine, and that degree in arts was only granted after four years' study. But while they had 1200 students in arts on their books not more than 300 of those were

students in medicine. They did not believe in a medical curriculum in arts. Therefore, if the Council came to a decision to require as a compulsory thing a modern language from a medical student, it would clash with the present regulations which had been considered and carefully revised several times during the last ten years, and which made Latin and Greek compulsory and modern languages optional. It would place the University in the unpleasant position of being practically called upon to alter their whole curriculum for all their students, or, on the other hand, if they still continued to follow out their own idea of arts culture, they might run the risk of their students ceasing to register. For these reasons he should vote against the motion.

Mr. TURNER said none of his propositions were intended at all to interfere with that portion of the recommendations of the Council which provided that a degree in Arts of any university in the United Kingdom or the colonies should be considered a sufficient test of preliminary education.

Dr. HUMPHRY moved as an amendment that Greek, French, and German be optional subjects, as at present. He considered that Mr. Turner's motion would practically exclude Greek, for if Latin and one modern language were made compulsory it would be almost impossible that students should take up Greek. The Council had to a certain extent gone out of its way to demand a preliminary examination, and no doubt had done well in doing so. The educational bodies had responded to the wish of the Council, and had modified their requirements accordingly; but if the Council put a strain upon them and demanded a foreign language, he could quite understand that they might be disinclined to respond to it.

Dr. A. WOOD seconded the amendment. If another compulsory subject were added to the curriculum he would much prefer that it should be mechanical philosophy.

Dr. PETTIGREW thought if an additional compulsory subject were introduced it should be Elementary Mechanics of Solids and Fluids, without which no step could be taken in physiology or anatomy.

Sir W. GULL said it would be a serious thing if after a parent had spent a small fortune on a boy in a public school where modern languages were held in contempt he should be rejected by the Medical Council because he did not know a little French.

Mr. HALDANE suggested that the Council had better first settle what subjects were to be compulsory, and then go on to the optional subjects.

This suggestion was approved of, and the amendment was withdrawn.

The motion was put and lost, five only voting for it.

MATHEMATICS.

Mr. TURNER moved, "That an examination in the Elements of Mechanics form a necessary part of the preliminary examination."

The motion was seconded by Dr. FERGUS, and agreed to.

On the motion of Mr. Turner it was also agreed that it should include Arithmetic, including vulgar and decimal fractions.

Mr. TURNER moved, "That Algebra, including simple equations, should also be included."

Mr. SIMON regarded simple equations as not worth having, and recommended that the algebra should extend to quadratic equations.

Sir JAMES PAGET agreed with Mr. Simon in his opinion as to the uselessness of simple equations; but as he had never in his profession found it necessary to use algebra, he thought if mechanics were added algebra had better be left out altogether.

Dr. ROLLESTON moved, and Dr. FERGUS seconded, "That quadratic equations be added."

Dr. ANDREW WOOD said they could not get quadratic equations.

Dr. HUMPHRY said the preliminary examination was already very extensive. By adding to it they would not improve general education, but would lead to more and more cram, and more superficiality.

The amendment, to include quadratic equation, was put to the Council, and rejected.

The Council then adjourned.

Tuesday, July 13th.

At the meeting of the Council to-day,

Dr. ROLLESTON asked the President whether any communication or reference had been made to him by the Govern-

ment on the subject of the Vaccination Bill. He said there could be no doubt that there would be an increase of mortality if there were any relaxation of the Vaccination laws. He was about to speak further on the subject, when

The PRESIDENT interposed, and said that it was out of order for a member to make a speech when asking a question.

The PRESIDENT said, as far as he knew, no communication had been made to him by the Government on the subject of the Vaccination Bill. A copy of the Bill had been sent to him by the President of the Royal Society, and addressed to him as President of the Medical Council; but on what ground it was sent, or whether in pursuance of instructions from the Government, he did not know.

The Council then went into committee for the consideration of the adjourned motion on preliminary examination.

Mr. Turner's motion, "That the examination in mathematics include algebra and simple equations," was put and carried.

Mr. TURNER moved that the examination in geometry include the first three books of Euclid or the subjects thereof.

Dr. ROLLESTON moved, as an amendment, the addition of Euclid, book iv. prop. 1—9.

Dr. HAUGHTON said it was absurd to stop short at proposition 9; the 10th proposition being, he said, the gem of the whole book.

Dr. ROLLESTON said he was willing to include the whole of the 14th Book, and would alter his amendment accordingly.

Dr. HUMPHRY opposed the introduction of the additional subjects, and said that the great examining bodies of the country only required the first two books of Euclid.

Sir JAMES PAGET also spoke against the addition, and said it would be difficult to compel all the bodies to conform to the wishes of the Council. If any additional subjects were prescribed, they should be such as would have a direct utility in regard to the study of medicine. It would be absurd to reject a student who came from Canada, for instance, simply because he had only been examined in two books of Euclid instead of four.

Mr. MACNAMARA objected to overloading the curriculum, and preferred a stricter examination in a more limited set of subjects.

Dr. BANKS said that the Queen's University recommended two books only, and he agreed in that recommendation.

Dr. PETTIGREW also opposed an overloading of the preliminary curriculum.

After some further observations from members of the Council, Dr. Rolleston's amendment was put and negatived.

Dr. HUMPHRY proposed another amendment, to the effect that two books of Euclid only, as at present, be required; and this was carried by a large majority.

Mr. TURNER said that taking stock of what had been done, he was afraid it would be best represented with a round O; for with the exception of two trifling alterations, they remained just as they were at the beginning of the discussion. They had recommended an examination either in English history or modern geography, and had struck out an objectionable foot-note to the effect that in the English examination a sufficient grammatical knowledge of the English language was all that was required. He regretted that the Council had not seen its way to add something to the requirements of the preliminary examination. Judging from the spirit which had been manifested by the Council, he feared that the motion he was about to make with regard to the elementary mechanics of solids and fluids might be rejected. Last year, however, a resolution on the subject had been passed by the Council, and the only reason why it had not been confirmed was that the Executive Committee found that there were certain technical difficulties in the way. All he asked of the Council at present was its sanction to the general proposition that the elementary mechanics of solids and fluids should form part of the preliminary examination. There might, however, be some difficulty in forcing the subject into the preliminary examination, because there were so many schools in which it was not taught; and he would therefore add to his resolution:—"It being understood that the examination in this branch may be passed either as preliminary, or before, or at the first professional examination."

Dr. HAUGHTON, in seconding the motion, said the subject included in it was absolutely necessary for the furniture of a student's mind. So great was the ignorance on the subject on the part of army officers in India, that

some of them did not know the difference between a barometer and a thermometer.

Dr. PETTIGREW approved of the introduction of the subject, but thought that it should be rendered compulsory before the commencement of the medical curriculum, and he moved an amendment to that effect.

Dr. A. SMITH expressed a similar view, and seconded the amendment. He said he did not think there would be any difficulty in the acquisition of sufficient knowledge of the subject. He believed that the educating bodies would fall in with the requirements of the Council in reference to a subject of so much importance.

Dr. ROLLESTON also moved an amendment giving the student the option of taking the elementary mechanics of solids and fluids; qualitative chemistry, with practical work; botany, geology, or the elements of logic.

Sir W. GULL seconded Dr. Rolleston's amendment.

Mr. SIMON said he would take his stand upon the resolution of the Council last year that the subject of elementary mechanics of solids and fluids should be recommended as one of the subjects "without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered." Local officers of health were taken from the rank and file of the profession; and how could they advise the local authorities on matters of ventilation, drainage, and the like, unless they possessed some knowledge of the subject in question? The period at which the knowledge was acquired was a matter of comparative indifference so long as it was regarded as compulsory before the giving of a registrable qualification.

Dr. A. WOOD hoped that the Council would not go back from its previous resolution.

After some further discussion Dr. Rolleston withdrew his amendment.

Dr. SCOTT ORR spoke in favour of Dr. Pettigrew's amendment, that the subject be made a compulsory part of the preliminary examination.

Dr. A. SMITH also urged the importance of making the subject part of the early training of the student.

Mr. TURNER suggested that his motion should be divided into two parts, and that a vote should first be taken on the simple question that there should be an examination in the elementary mechanics of solids and fluids, making the period at which it was taken the subject of a distinct motion. This course was agreed to, and the question was unanimously decided in the affirmative.

Sir W. GULL ridiculed the idea of the Council going over the same ground as last year, and said they appeared to be constantly deciding the same thing over and over again, and always congratulating themselves on their success.

Dr. Pettigrew's amendment was then put and negatived, and Mr. Turner's motion as to the period of the examination was carried by a large majority.

Mr. TURNER then moved: "That the examination in the Elementary Mechanics of Solids and Fluids comprise statics, hydrostatics, and dynamics," which, after a short conversation, was agreed to.

This concluded the discussion on compulsory subjects.

Dr. FERGUS then brought forward a motion relating to the optional subjects. He said he had been accustomed to regard the Council as a body which aimed at elevating the education of the profession, but he was now afraid that they had been leveling down instead of up. They ought to have increased the stringency and breadth of the examinations. More than one-third of the candidates who came up to the first professional examination were rejected. Such a state of things ought not to exist. The preliminary examination should be such as would weed out the incompetent, and therefore should be greatly extended. Instead of that the Council had for the last few days been bringing the examination down to the level of boys fresh from school. It had been said that in the interest of the practitioner it should be made as easy as possible, but if any man entered the profession merely as a trade for a morsel of bread and cheese and silver he would be the most miserable being in the world. His object should be the performance of duty. The Council should not try how rapidly they could manufacture doctors, but in every way to elevate them. He moved: "That one of the following optional subjects must be passed as preliminary—namely, French, German, Greek, Logic, Moral Philosophy, Botany, Chemistry, Zoology, Geology."

Dr. ROLLESTON seconded the motion.

Mr. SIMON said he was not quite clear that even one

optional subject was necessary, but he thought a distinction might very properly be drawn according to whether or not the examination in the elements of mechanics had been passed as a part of the preliminary. He was disposed to think that if a candidate practically said, "My educational circumstances have not allowed me to learn elementary mechanics in time for the preliminary examination," an optional subject should be required. In that way he would hold out an inducement to the students to pass the examination in elementary mechanics as a preliminary, and if they did so they should be excused from all the optional subjects.

Dr. HAUGHTON thought chemistry should be excluded from the list. The Council would have a very mean opinion of what chemistry was if they considered the wretched schoolboy knowledge as sufficient. A few years ago, when intermediate examinations for Ireland were started, meetings of all the schoolmasters in the country were held, and the overwhelming majority were of opinion that the amount of chemistry that could be acquired at school was not worth possessing. Any one who had experience in teaching higher chemistry knew that when a schoolboy came to learn it the first process he had to undergo was to unlearn all that he had previously learned of so-called chemistry. Contrary to the advice of the Irish schoolmasters chemistry was kept on last year by the Intermediate Education Commissioners, who thought, like the Council, that they were a great deal wiser than those who had practical knowledge of the subject. The result was that the highest prizes at the examinations in chemistry were taken by men who had never seen an experiment in their lives, and who had obtained all their knowledge from books.

After some discussion, it was agreed to postpone the question of whether one or two of the subjects should be required until the subjects themselves had been decided upon.

French, German, and Greek were agreed to.

On the suggestion of Mr. TURNER, Italian and Dutch were added to the list.

Logic was also agreed to.

On the proposal to include Moral Philosophy,

Dr. HAUGHTON said this was a subject which required a mature mind, and he thought it would be a misfortune to send forth into the profession a crowd of pert prats who fancied they understood it. He would not give sixpence for all the knowledge of moral philosophy which a schoolboy could possess.

On being put to the vote, the proposal was negatived.

Botany was agreed to.

With regard to the proposal to include Chemistry,

Mr. TURNER said he should like to know what was meant by putting it as an optional subject in the preliminary examination. Was it intended by doing so to exclude chemistry from forming a necessary part of the professional examination? If that was so, he should most strongly protest against it. It was perfectly clear that such a knowledge of chemistry as was necessary for the requirements of the profession in regard to physiology, pathology, materia medica, and therapeutics could not be tested by any examination that could be imposed upon a student in the course of his preliminary. He would be sorry if the Council adopted any resolution which would lead the licensing bodies or the students to believe that, if acquired, a certain minimum of chemistry for the preliminary examination that would absolve them not merely for further examination in the subject, but also for attendance on a systematic course of lectures and instruction.

Dr. PITMAN drew attention to the fact that there were no less than ten optional subjects proposed, and the preliminary examining boards must be prepared to meet the requirements of every candidate. That was a very serious matter, and the Council would do well to limit the number of its subjects.

Mr. TEALE said what was intended was that the door should be opened for a student to select an examining board which was prepared to test him in his special subject.

Dr. HUMPHRY agreed with Mr. Teale's view. With regard to the examination in chemistry, he thought there was nothing that would prepare a man for his future studies in medicine better than a rudimentary knowledge of chemistry. He did not set so low an estimate as Dr. Haughton did on the knowledge of the subject which could be obtained from books. He remembered that on one occasion at Cambridge a man attained a very high position in chemistry, though it was well known that he had received no practical instruction in it. Of course it could not be a perfect knowledge, and

he would not think of substituting the preliminary for the professional examination in chemistry.

Dr. WOOD considered it a most heretical doctrine to lay down that anyone could learn chemistry from a book, and if it was allowed to be scamped at first the students would not devote themselves to a serious study of it in after life.

Dr. ROLLESTON regarded chemistry as the very alphabet of natural science, and thought it should be recognised in the preliminary examinations.

Dr. SMITH said all that Dr. Fergus meant by the proposal was the merest elementary chemistry, and it was most desirable to introduce that into the preliminary examination.

Dr. STORRAR said there were a great number of schools in which chemistry was taught in the laboratory, and he was in favour of including it among the optional subjects.

Elementary Chemistry was then agreed to, but Elementary Zoology and Elementary Geology were negatived.

Mr. SIMON suggested that a higher qualification in one of the compulsory subjects should be regarded as a substitute for a smattering in one of the optional subjects.

Dr. FERGUS said he had at first intended to include higher mathematics, and was quite prepared to propose it now.

Dr. HAUGHTON seconded the motion, which was lost.

A short discussion followed upon the question whether one or two of the optional subjects should be required. It was ultimately resolved that only one should be regarded as necessary.

Mr. SIMON moved as a rider to the resolution: "Provided that if the candidate have passed his examination in the Elementary Mechanics of Solids and Fluids he shall be excused for the examination on the optional subject."

Dr. HUMPHRY seconded the motion, which was negatived.

The Council then resumed. The Registrar read the whole of the resolutions passed in Committee, and Mr. Turner moved their adoption.

The Council then adjourned.

Wednesday, July 14th.

The Council reassembled under the presidency of Dr. Acland.

Mr. TURNER asked the President if he could furnish the Council with information why the Naval Medical Department had ceased to furnish a statement of the results of the examinations for admission to the Medical Department of the Navy; also if the returns from the Army Medical Department include the candidates for commission in the Medical Department of the Indian Army.

The PRESIDENT replied that there had been some delay in obtaining the desired information, and he was unable to give a complete answer. He had reason, however, to believe, from communications he had had with both Departments, that there would be no difficulty in obtaining the information.

Dr. HAUGHTON said that the subject was under the notice of Parliament, and it was important that the information asked for should be communicated.

The PRESIDENT said that as soon as it was received it should be communicated to the Council.

Mr. SIMON called attention to an answer given by the President on Tuesday with reference to the transmission to him of a copy of the Vaccination Bill by the President of the Royal Society, and he said he assumed that document was sent by Mr. Spottiswoode in his private capacity, and not officially. He said he had himself received a copy of the Bill from Mr. Spottiswoode.

The PRESIDENT stated that the document had been sent to him on Royal Society paper, and was addressed to him as President of the Medical Council. In former years there had been considerable inconvenience from their seeming to be compelled to receive communications on all sorts of subjects, and he had acted in the cautious way described, not knowing whether the communication in question was to be considered as official.

The debate on Mr. Turner's motion for the adoption of the resolutions passed by the Council with regard to preliminary examination was resumed.

The following resolutions were adopted without discussion:—(1) "That an examination in English form part of the preliminary examination." (2) "That the examination in

the English language be such as is now provided for in the 'Recommendations' of the Council, except that the last two lines of the footnote to p. 8 of the last edition of the 'Recommendations' be in future omitted."

On the motion (3) "That No. 2 of clause 4 of the 'Recommendations' be as follows: either English History or Modern Geography," Dr. QUAIN suggested the substitution of the word "and" for "or," and contended that the two subjects could not well be separated. Mr. Turner adopted the suggestion, and the motion was altered accordingly, and agreed to.

The following resolutions were adopted without discussion:—(4) "That an examination in one Ancient Language form a part of the preliminary examination." (5) "That Latin, including Translation from the original and Grammar, be the Ancient Language which is to be rendered compulsory." (6) "That an examination in the Elements of Mathematics form a necessary part of the preliminary examination." (7) "That the examination in Mathematics comprise: (a) Arithmetic, including Vulgar and Decimal Fractions." (8) "That the examination in Mathematics comprise: (b) Algebra, including Simple Equations." (9) "That the examination in Geometry comprise, as at present: (c) Geometry, the first two books of Euclid or the subjects thereof." (10) "That there be an examination in the Elementary Mechanics of Solids and Fluids." (11) "That it be understood that the examination in the Elementary Mechanics of Solids and Fluids may be passed either as preliminary, or before, or at the first professional examination, so that the passing of this examination is not to be regarded as necessary for registration." (12) "That the examination in the Elementary Mechanics of Solids and Fluids comprise the Elements of Statics, Dynamics, and Hydrostatics."

Mr. TURNER proposed the adoption of the next resolution:—(13) "That the following be the optional subjects: Greek, French, German, Italian, Dutch, Logic, Botany, Elementary Chemistry."

Greek, French, German, and Italian were adopted as optional subjects without discussion.

Dr. ROLLESTON opposed the introduction of Dutch—a language which, he said, was of very little value in the way of mental training.

Sir JAMES PAGET thought if Italian were to be taken as an optional subject, Dutch should also be included. There was a great deal of good scientific literature in that language.

Dr. HAUGHTON suggested that, instead of Dutch, "any one modern language" should be accepted.

Mr. TURNER accepted the suggestion.

Sir WM. GULL asked the Council not to make itself ridiculous. He believed that all the work of the last few days had been a mistake. The question discussed should have been referred to a committee of gentlemen who were well acquainted with the education of boys up to sixteen or seventeen. With regard to the proposal to examine in Dutch, he thought they might as well propose to examine in the patois spoken in the Channel Islands or in Sanscrit.

Dr. PETTIGREW said, if a student presented himself for examination in Dutch, and there was no examiner to be found, the examining body would be in a serious fix.

Dr. A. WOOD said the Council would be adopting a ludicrous course if it assented to the proposal, and he strongly opposed it.

After some further discussion, the proposal for the adoption of "any one modern language" was agreed to.

Logic, Botany, and Elementary Chemistry were also agreed to as optional subjects.

Dr. HAUGHTON moved the addition of zoology (which he thought ought not to be separated from botany) to the optional subjects.

Dr. BANKS seconded the motion, and said that zoology was taught in all the national schools in Ireland.

The motion was negatived.

It was then resolved, "That one of the foregoing optional subjects be made compulsory."

On the motion of Mr. TURNER, seconded by Sir JAMES PAGET, the following resolution was agreed to:—"That the General Council's amended Recommendations on education and examination be communicated to the several examining boards, whose examinations are recognised by the Council, that their attention be drawn to the changes which have been made; that they be informed that the Council proposes that the additional requirements be not made obligatory on students until Jan. 1st, 1882; and that on and

after that date no person be allowed to be registered as a medical student unless he shall have previously passed a preliminary examination in the subjects of general education as specified in the following list" (the list agreed to during the present session).

Mr. SIMON proposed: "That, in the opinion of the Council, it is desirable that intending candidates for the medical profession should, before they enter on the purely medical curriculum, have been instructed and examined in the rudiments of natural science—physical, chemical, and biological, and that, in proportion as this can be done, the present medical curriculum and present professional examinations should be lightened of all such matters." He said there was no reform on which competent persons were more entirely agreed than the necessity of their getting, if possible, a preliminary scientific examination; it would be a most important assistance to the progress of medical education in this country.

Dr. FERGUS seconded the motion.

Mr. TURNER said he was entirely at one with Mr. Simon as to the importance of having an examination in the natural sciences as a part of the general training required from students of medicine, and that the examination on these subjects should, of course, take place before the examination in subjects more directly bearing on medical training. He should like, however, to have some further information as to what Mr. Simon meant by the "rudiments of natural science"; was it intended to place this examination on the same level as the elements of chemistry and botany which they were willing to accept as optional subjects, or was it to be something further, and to be taken after registration?

Mr. SIMON said he had endeavoured to avoid unnecessary detail. The Council was not a regulating body, but a recommendatory one, and they would be troubling themselves needlessly by going minutely into detail provided the principle was properly stated. The examination should be after the preliminary general examination, and before commencing the distinctively medical curriculum, or at the latest before the end of the first year. It should, in his opinion, embrace an elementary knowledge of mechanics, solids, and fluids, of heat, weight, and electricity, of general chemistry, and of the constitution of plants and animals.

Sir JAMES PAGET was satisfied that no conclusion could be arrived at on this subject during this session of the Council, and, therefore, if Mr. Simon's motion was adopted it must be on the understanding that it should not come before the Council, but should be referred to a committee.

Sir WILLIAM GULL, in supporting the motion, said the result would be that more time must be occupied in the study of the profession than was the case at present. It was quite impossible to educate a man so that he should be fit to enter on the practice of his profession at the age of twenty-one. It could not be done, and, therefore, they ought to ask that a man should be twenty-three at least, and perhaps twenty-four, before he was entitled to practise. In making this inquiry they certainly must take in the whole question of professional time.

Dr. HAUGHTON said the practice of the University of Dublin was precisely in accordance with the proposal of Dr. Simon, the Arts curriculum and the medical teaching occupying together six years. He did not object to the resolution, but it must involve an additional time of study after registration before commencing practice.

Dr. ANDREW WOOD said this was a very important subject, and one well deserving the consideration of the Council, but he might put it to Mr. Simon, whether on this the penultimate day of the session the Council was in a condition to enter upon the consideration of this matter. He had made out a very good case for a Committee, and no doubt a Committee over which Mr. Simon presided would be able to lay before the Council a most valuable report. It would be a most important subject to bring before the next session of the Council.

The motion was then put to the Council, and agreed to.

Mr. SIMON, after expressing his gratification at seeing the principle of his resolution so entirely approved by the Council, moved: "That this resolution be referred to a Committee of seven, with instructions to propose to the Council before the close of the present session the draft of a communication to be addressed to the licensing authorities with a view to giving it practical effect." He did not propose anything like a Committee of investigation, but simply a Committee to draw up a letter to be sent to the licensing bodies.

Dr. FERGUS seconded the motion.

Mr. TURNER thought there would be some difficulty in getting a satisfactory communication drafted and approved by the Council this session, as it would no doubt involve some discussion.

Mr. MACNAMARA suggested the omission of the words, "to giving it practical effect," and substituting "of getting their opinion thereon." That would not pledge the Council to anything, and would enable the licensing bodies to forward by the next meeting of the Council a report that would be very valuable for the discussion of the subject.

Dr. HALDANE, although entirely agreeing with the principle involved in Mr. Simon's resolution, would not vote for it, because it involved so complete a change in medical education. This was a point of very great importance, and the Council should not take action in the matter without consulting the various licensing bodies. He therefore proposed as an amendment: "That the Council having agreed to the preceding resolution, a copy of this resolution be sent to each of the licensing bodies, with a request that they will at an early date express their opinion on the subject."

Dr. ANDREW WOOD seconded the amendment.

Sir JAMES PAGET said if the amendment was carried it would really defer all possible progress until the beginning of next session. He urged the formation of the Committee, whereby the whole information might be collected and placed before the next meeting of the Council.

Mr. SIMON, in order to meet objections, asked leave to withdraw his motion and to substitute the following: "That the resolution be communicated to the licensing authorities under the Medical Act, and that it be recommended to those authorities to consider whether they can separately or conjointly take steps to promote the establishment of a preliminary scientific examination, and to require of candidates for their respective licences that after passing the preliminary examination in general education, and either before commencing the purely medical curriculum or at latest before the end of the first year thereof, shall pass such preliminary scientific examination as is proposed."

After some further discussion Dr. Haldane's amendment was put in the following form: "That a Committee be appointed to communicate on the subject with the licensing bodies, and to report to the Council at its next meeting." This was agreed to.

On its being put as a substantive motion,

Mr. MACNAMARA moved as an amendment: "That this resolution be referred to a Committee of seven, with instructions to propose to the Council before the close of the present session the draft of a communication to be addressed to the licensing authorities, with a view of getting their opinion thereon."

Mr. SIMON seconded the amendment, which on being put to the Council was negatived by a majority of 10 to 9.

The motion as proposed by Dr. Haldane was then put and agreed to.

The Committee was appointed, comprising Dr. Storrar, Dr. Rolleston, Dr. Hudson, Mr. Turner, and Dr. Haldane, with power to add to their number.

Mr. SIMON then moved the following resolution: "That in Section 3 of Chapter 1 of the Council's Recommendations on Education and Examination the list of bodies from which testimonials of proficiency in preliminary general education may, in the opinion of the Council, be properly accepted by the licensing authorities under the Medical Act, be amended by omission of its Part II—this amendment to take effect on and from the 1st of January next; and that notice be forthwith given to each licensing authority that after the end of the present year the examinations mentioned in Part II. of the aforesaid list will not be regarded by this Council as satisfactory for the purposes of the Medical Act." He was proceeding in his address to the Council in support of the motion when the time for closing the discussion arrived, and the debate was adjourned.

An application for registration by Mr. Nathaniel Chappell, referred to the General Council by the Executive Committee, was refused.

The Council then adjourned.

Thursday, July 15th.

The Council was occupied during the early part of to-day's sitting with Dental business. A motion was passed to the effect that the bodies conferring licences in Dental Surgery be requested to furnish yearly a statement of the nature of

the examinations, and the number of candidates, showing the numbers passed and rejected. Certain letters received from the British Dental Association, and other persons, with reference to Dental Registration, were referred to the Dental Committee. A motion to the effect that the opinions of counsel on Dental Registration should be read was adopted; but strangers were requested to withdraw, and the Council deliberated on the subject for some time in private. The later hours of the sitting were devoted to the further consideration of Mr. Simon's motion, proposed on Wednesday, with reference to testimonials of proficiency in preliminary general education. After a lengthened discussion, at the suggestion of Dr. Storrar, who seconded the motion, the motion was withdrawn, and the Council adjourned to Friday.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

New and Old Swindon.—New Swindon is the town created by the Great Western Railway Company in the vicinity of the station on its line so well known to travellers. Old Swindon is the neighbouring town, and the original Swindon from which the railway station and the new town took their name. Last year both towns suffered from a severe outbreak of scarlet fever, and the Local Government Board directed their inspector, Dr. Blaxall, to make inquiry as to the circumstances of the outbreak, and generally as to the sanitary condition of the two towns. The report of this inquiry has now been made public. It describes of both towns that common-place condition of things which is now so frequently found in small towns, and which we must look to another generation fully to remedy. Both towns have not hesitated to spend money on sewerage; and New Swindon is supplied wholly, Old Swindon partly, with fair water from the works of a Company. But the sewerage is incompletely carried out in several important respects. Old Swindon has still recourse too largely to shallow wells; and in both towns that continuous sanitary supervision and care, without which the best arrangements for sewerage and water-supply must largely fail of their object, are conspicuously wanting. Both towns carefully store their excrement in privies adjacent to the houses; and both hold the medical elements of their sanitary work properly provided for by appointing medical officers of health, one each, at a salary of £10 a year—New Swindon having a population of 16,000, and Old Swindon of 4250! Dr. Blaxall's recommendations indicate that the ordinary sanitary administration of both places is generally neglected, and that in respect to infectious diseases there is no serious hope of checking them until the administration is much amended.

Castleford Registration District.—An unusual prevalence of scarlet fever and enteric fever in this district led the Local Government Board, early in the year, to cause a medical inspection of it to be made by Dr. H. F. Parsons. His report of the results of this inspection is now before us. The district contains four principal centres of population, Castleford, Whitwood, Methley, and Glass Houghton, and the report instructively illustrates the slowness with which sanitary work makes progress among semi-rural communities. Castleford has been the subject of repeated official inquiries regarding its sanitary condition, nevertheless, after the expenditure of much money, and notwithstanding the aid of extraneous skilled advice, Dr. Parsons describes much that is defective in the sanitary administration and state of the town. This, it appears, is not to be attributed to parsimony, but to the failure of the Sanitary Authority "to apprehend and apply the ascertained principles of sanitary science to the suppression in details of the particular nuisances which have characterised the district from the time of Mr. Babbage's inquiry [for the General Board of Health] in 1850 to the present time." An instructive illustration of the wasteful inaptitude of the sanitary authority in carrying out its work is given in an account of their attempt to introduce a pail system of excrement disposal,

and the frustration of the attempt by their way of going about it. Whitwood and Methley (Glass Houghton being included in the district administered for sanitary purposes by the Pontefract Rural Sanitary Authority) have the common characteristics of West Riding communities, which depend on shallow wells for water-supply, on the old-fashioned open midden privy for the deposit of excrement, and on surface drains for drainage. Whitwood has begun to sewer, and so far gives promise of amendment; Methley stands at ease, so to speak, in her filth. Scarlet fever and enteric fever are endemic in the registration district, and the mortality among infants from diarrhoea there is "excessively" high. A much higher standard of sanitary administration will have to be reached before reasonable hope of holding in check scarlet fever or removing the conditions fostering enteric fever can be entertained. Dr. Parsons terminates his report by a long list of recommendations to the several sanitary authorities in the district—recommendations which pretty well cover all the things they were appointed to do, and have not done.

SMALL-POX IN DUBLIN.

The Public Health Committee of the Corporation of Dublin have recently issued a report on the prevalence of small-pox in that city. They refer to the neglect of the Guardians in not putting into force the powers conferred on them by the Vaccination Act, and recommend that vaccination should be made compulsory. They believe that there is much force in the suggestion that temporary houses should be provided for families in which infectious disease has occurred, pending the disinfection of their dwellings, and that observation wards and a convalescent home should be established. Further, that the governors of the Cork-street Fever Hospital be requested to help in establishing a hospital for the treatment of small-pox patients and a convalescent home in connexion with their hospital; the Corporation to contribute to the erection and maintenance of such an institution. We may add that during the June quarter 125 deaths were registered in Dublin from small-pox, being an increase of 64 as compared with the first three months of the present year.

THE PUBLIC HEALTH (IRELAND) ACT (1878) AMENDMENT BILL.

A Bill has been introduced into the House of Commons by Mr. Redmond and others to amend the Public Health (Ireland) Act, 1878. This Bill provides that notwithstanding anything contained in that Act the Local Government Board may, on the application of the urban sanitary authority of any urban district, vary, amend, or enlarge any existing provisional order, notwithstanding that such provisional order was obtained previous to the passing of the Public Health (Ireland) Act, 1878.

THE "FEVER" IN MAYO.

Mr. W. E. Forster laid upon the table of the House of Commons on the 12th inst. a report received from Dr. Nixon, who had been sent to the fever-stricken districts of Mayo to report on their condition. Notwithstanding the warnings given several months ago with regard to the probable appearance of fever sooner or later among the populations of these districts, it is to be gathered from the report that they had been unheeded, and that the guardians were quite unprepared to deal with the outbreak. The sanitary condition of the infected districts is described as deplorable. From other sources we learn that both maculated typhus and relapsing fever exist there.

In answer to a question from Mr. Hastings, the President of the Local Government Board stated in the House of Commons on the 12th inst. that some further time must elapse before his department would be able to commence the issue of vaccine lymph from the calf. He observed that as the department would be held responsible for the quality of the lymph, great care was necessary in maturing the plans for its cultivation and issue.

The vestry of St. Mary Abbott's, Kensington, as sanitary authority for that important district of the metropolis, have prepared a petition for presentation to Parliament against the Vaccination Acts Amendment Bill. The petition has been published in the form of a circular prefaced by an abstract from a report on the subject by Dr. Dudfield, their medical officer of health.

Mr. J. A. Forrest, the Chairman of the Scavenging Subcommittee of the Liverpool Corporation, has prepared a report on the final disposal of those products of the scavenging operations of that city which possess no value to the farmer. It would seem that in Liverpool part of these materials is used in raising the level of new streets and in covering marsh lands along the line of the Lincolnshire canal, and part has been carried out to sea in a barge constructed for the purpose and sunk there. It proves that the carriage of these refuse matters out to sea is the most economical method of disposal, and the Corporation is to be asked to sanction the construction of one or more additional barges.

The question of a district medical officer ordering out-door relief was considered at a recent meeting of the Medway Board of Guardians, one of the general inspectors of the Local Government Board being present. It seems strange that a question of this sort should arise, seeing how clearly the Orders of the Central Authority set forth the respective duties of the medical officer and relieving officer; and it causes a suspicion that the Poor Law Authorities are not sufficiently careful in making medical officers, when first appointed, acquainted with the rules which should govern the performance of their duties.

The members who represented St. George's, Hanover-square, on the deputation from metropolitan vestries and Boards of Guardians to Mr. Dodson, on the Vaccination Amendment Bill, reported the result of their interview with that gentleman to the meeting of their Board on the 7th instant, and the Board passed the following resolution:—"That this Board regret the introduction of the Bill limiting the penalties for refusing to have children vaccinated, and would gladly see the compulsory powers increased by giving the Guardians power to enforce the Act."

The Eccles and Barton Local Board, it is reported, have had to request their medical officer of health to refrain from introducing political controversy into his reports. In a recent report, it appears, this gentleman had offered some observations on the free-trade policy of the country, he, seemingly, being a staunch protectionist; and in so doing he had given offence to the Board.

The recent heavy downfalls of rain have caused overflows from the sewers and flooding of basements in several parts of the metropolis. The evil seems to have been most markedly experienced in Limehouse, along the line of the low level main-sewer. Deputations from the several districts which have suffered have had interviews with the Metropolitan Board of Works on the subject.

A story is current in the press of a sewer-man at Chester having narrowly escaped suffocation in the mud of a blocked sewer. When will the local authorities of our ancient cities learn that it is a disgrace to lag behind the time in matters of sewerage, and that even the antiquity of a place does not justify the retention of arrangements for the disposal of filth which are pernicious to the inhabitants?

Scarlet fever, which has been prevalent at New Brompton, is now reported to have disappeared from the locality.

VITAL STATISTICS.

HEALTH OF LARGE ENGLISH TOWNS.

The rate of mortality in our large English towns continues unusually low. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5072 births and 2760 deaths were registered last week. The births were 113, and the deaths as many as 515, below the average weekly numbers during 1879. The deaths showed an increase of 38 upon the number returned in the preceding week, and were equal to an annual rate of 19.2 per 1000, against 18.9 in each of the previous three weeks. During the thirteen weeks which ended on the 3rd inst. the death-rate in these towns averaged but 20.4 per 1000, against 23.3, 22.7, and 22.2 in the corresponding periods of the three years 1877-78-79. The lowest death-rates in the twenty towns last week were 10.1 in Hull, 13.2 in Birmingham, 14.6 in Brighton, 14.7 in Bristol, and 15.6 in Portsmouth. The rates in the other towns ranged upwards to 21.4 in Manchester, 23.7 in Salford, 24.1 in Sunderland, 25.3 in Liverpool, 28.9 in Oldham, and 29.8 in the city of Norwich. The comparatively high rates in these

last-mentioned towns, with the exception of Manchester, were due to excessive zymotic fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had risen from 406 to 476 in the four previous weeks, further rose in the week ending Saturday last to 522; these included 183 from diarrhoea, 130 from scarlet fever, 81 from measles, and 74 from whooping-cough. The annual death-rate from these seven diseases averaged 3.6 per 1000 in the twenty towns; it was but 1.4 in Wolverhampton and 1.9 in Brighton, whereas it ranged upwards to 5.9 and 7.3 in Salford and Norwich. Scarlet fever showed the largest proportional fatality in Norwich, Sheffield, Sunderland, and Salford; measles in Leicester, Oldham, and Sunderland; and whooping-cough in Norwich, Liverpool, and Bradford. Small-pox caused four deaths in London and one in Birmingham, but not one in any of the eighteen other large towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the two preceding weeks had been 237 and 216, further declined to 191 on Saturday last; 17 new cases of small-pox were admitted to these hospitals during last week, against 50, 47, and 38 in the three preceding weeks. The number of patients in the Highgate Small-pox Hospital was 10, against 11 and 10 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 176 and 177 in the two preceding weeks, were 171 last week, and corresponded with the corrected weekly average; 99 deaths were referred to bronchitis and 51 to pneumonia. The annual death-rate from diseases of this class did not exceed 2.4 in London, whereas the rate from the same diseases was equal to 3.5 in Liverpool, and 4.5 in Salford.

HEALTH OF LARGE SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20.4 per 1000, against 20.6, 20.5, and 20.9 in the three preceding weeks; it exceeded, however, by 1.2, or 6 per cent., the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 13.3 and 14.6 in Leith and Aberdeen, to 23.4 and 25.5 in Perth and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns were 97 last week, and included 36 from diarrhoea, 20 from whooping-cough, 15 from scarlet fever, 9 from measles, and 9 from fever. The annual death-rate from the seven diseases averaged 3.9 per 1000 in the eight towns, and in the twenty English towns it was 3.6; this zymotic rate corresponded with the average of the three preceding weeks, and while it was but 1.0 in Aberdeen and 2.3 in Dundee, it ranged upwards to 5.3 and 5.8 in Paisley and Perth respectively. The 9 deaths from fever showed a decline from the recent increasing weekly numbers, and included 5 in Glasgow. The mortality last week from measles decreased, whereas that from scarlet fever showed a marked excess. The 36 deaths from diarrhoea exceeded by 11 those returned in the previous week, and included 19 in Glasgow, 6 in Dundee, and 4 in Edinburgh. A fatal case of small-pox was returned last week in Glasgow, the first from this disease in any of the Scotch towns since the week ending 3rd April last. The deaths from acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 79 and 91 in the preceding weeks, were 90 last week, and were equal to an annual rate of 3.6 per 1000; the rate from the same diseases in London last week did not exceed 2.4 per 1000. As has been noticed in recent weeks, the excess of mortality in the Scotch towns compared with the English appears to be mainly due to the excessive mortality from lung diseases and to zymotic fatality.

THE HEALTH OF DUBLIN.

The annual rate of mortality in the city of Dublin, which had been 32.7 and 33.7 in the two preceding weeks, declined last week to 31.2, the lowest rate recorded in any week since the beginning of April. The annual rate of mortality in Dublin during the thirteen weeks on the 3rd inst., without any correction for defective registration, averaged no less than 36.6. In London, during the same period, the death-rate averaged but 19.4 per 1000. The 188 deaths in Dublin last week included 47, or 25 per cent., which were referred to the seven principal zymotic diseases, against 48 and 53 in the two preceding weeks; 12 resulted from scarlet fever, 10 from small-pox, 9 from whooping-cough, and 9 from

fever. The annual death-rate from these seven diseases was equal to 7·8 per 1000 in Dublin, against 3·6 in London, and 3·4 in Edinburgh. The fatal cases of small-pox, which were 19 and 14 in the two preceding weeks, further declined to 10 in the week ending Saturday last.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

FAMINE AND DEARTH.

Although under the term of the "Irish distress" (and careful avoidance of the word "famine" with reference to Ireland), we have sought to veil from ourselves, after a fashion, the actual suffering from scarcity of food in the distressed districts in the sister island, there can be no doubt that we have been and are dealing there with famine in a sufficiently painful, although not in its most painful, form. We may congratulate ourselves, at least, on having been able to stave off that awful extremity of famine which has existed for several months, and still unhappily exists, in parts of Asia Minor. The scarcity observed in Ireland is but one of many manifestations of scarcity which have occurred, or are now occurring, over vast tracts of territory in Europe, Asia Minor, and in Central Asia. The state of the southern and eastern provinces of Russia in respect to food is such as to awaken the profoundest anxiety. There is little doubt that in not a few localities the scarcity is such that the peasantry must be suffering actual famine, and the prospect for the coming winter is of the darkest. The food supplies kept in store were so largely exhausted by the sufferings of the past winter that in not a few districts the seed corn was consumed, and large tracts of ground were unsown. Moreover, such crops as were sown, and which during the spring gave promise of abundant harvest, have been now very largely destroyed by an invasion of locusts and other insects. The local governments are in despair in face of this dreadful plague of insects. Hands fail to deal effectually with it. Migrations during the dearth of winter partly depopulated some districts, and in others the superstitious feelings of the peasantry have proved an effectual impediment to their rendering help to save themselves from the impending scarcity. "It is the will of God," they say, and it is questionable whether even the interference of the Church will serve to remove their apathy. Rye, which forms the staple food of the peasant and lower orders, and which in June, 1875, sold in St. Petersburg at 6 roubles 40 c. the 8 pouds, 32 lb., had risen to 11 roubles and 50 c. for the same quantity in June, 1880. It is probable that we shall never know accurately the details of the dreadful famine which prevailed over a great part of Central Asia during the last winter and spring, and which there is reason to believe annihilated several tribes. The famine which still prevails over a large part of Asia Minor, of Kurdistan, and of Turkish Arabia, has become better known to us through numerous correspondents in the daily press, and the reports from the various missionary stations in the distressed districts. The famine in European Turkey appears to have attracted less attention, but, nevertheless, it would seem that the population of the districts visited by the late war are suffering from extreme destitution, and in some of them the people are dying from actual famine.

THE OUTBREAK OF FEVER IN SWINFORD UNION.

Dr. Grimshaw, Registrar-General for Ireland, has recently gone through the records for the Swinford district for the past ten years, and has analysed minutely those for the last year and the first half of the present. During the ten years he finds that fever has prevailed there—in fact, is endemic—and that there is, therefore, nothing remarkable about its presence this time more than at any other. Beginning with 1870, in that year there were 24 deaths from fever, in the next 25, in the next 22, in the next 38, in the next 33, in the next 13, in the next 18, in the next 16, in the next 36, and last year there were 48 deaths. In the first half of the present year there were altogether 22 deaths from fever, while in the first half of last year there were 23, so that this half year there has been one death less than in the corresponding period of last half. In the second quarter of this year there have been 8 deaths from fever in the whole of the Swinford Union, which contains a population of 53,000. For the first half of this year the deaths from all causes in Swinford Union has been

508, while in the corresponding period of last year it was 585, or a decrease of 77. The most fatal epidemic disease during the last year has been whooping-cough, which has proved very destructive. The average death-rate of the Union has been only 14·8 per 1000 for the ten years, and the average death-rate per annum for the second quarter during the ten years has been 12·5, while for the second quarter this year it was 18·8, which is probably below the average for the whole of Ireland. So far as can be ascertained, these outbreaks of fever are quite common among the people of Ireland. For example, there has been on outbreak on the Kilkerran Islands, another in Skibbereen, another in Donegal, besides others at places where there has been no exceptional distress at all.

THE "HOWARD MEDAL."

It is announced that five essays have been received by the Council of the Statistical Society in competition for the "Howard Medal" of the present year, the subject being "The Oriental Plague." It is further announced that the subject for the Howard Medal for 1881 is "Jail Fever, from the earliest Black Assize to the last recorded outbreak in modern times."

The municipality of Paris have decided to establish (as a beginning) three ambulances, to be distributed in various parts of the city, for the removal to hospital of persons suffering from infectious sickness, hitherto the ordinary public carriages having been used for the purpose. Much importance is now being attributed in Paris to the introduction of infection by travellers in reference to recent outbreaks of disease there. It is stated that the later prevalences of small-pox have all begun in furnished apartments, and these and hotels are to be subjected to special supervision in view of infectious diseases.

The Sanitary Institute of Great Britain held its anniversary meeting in the Royal Institution on the 8th inst. The Earl of Shaftesbury, K.G., presided, and distributed the medals and certificates awarded for useful sanitary inventions and appliances exhibited at Croydon last year; and Captain Douglas Galton, R.E., C.B., read a paper on "Some Preventible Causes of Impurity in London Air." In the evening the members of the institute dined together at the St. James's Hall Restaurant, Dr. B. W. Richardson in the chair.

We learn that the reports as to the prevalence of small-pox in Norway are much exaggerated. To the 8th inst. the total number of cases which had occurred amounted to 120, of which 89 had taken place in Christiania. Of these cases 7 (all young unvaccinated children) had proved fatal.

Recent reports from Russia state that diphtheria is raging among the working classes of the government of Saratov; but that the disease is declining in the government of Catherinoslav.

INTERNATIONAL MEDICAL CONGRESS.

At the meeting of the Committee of Organisation, held on Tuesday last, the list of sections and officers subjoined was finally decided upon. The Congress will meet from the 3rd to the 9th of August, 1881, in rooms granted by the University of London and the Royal and other learned Societies meeting in Burlington House. Invitations to attend the meetings will be issued to all legally qualified medical practitioners in the United Kingdom, and will be sent to the different countries of Europe, to America, the Colonies, and India. Papers may be read in English, French, or German, and will be published in the volume of Transactions in the language in which they are read. We presume it is only an oversight that the word "male" is omitted from the qualifications of those to whom invitations are to be sent. The names of many of the officers of the sections are an assurance that the "lady-doctors" will not be asked to attend and contribute; but if by any want of clearness in issuing the invitations mistake should occur, a very considerable proportion of the leading members of the profession will, of course, decline to co-operate. The point should be determined at once.

It will be necessary for all who wish to make communica-

tions to the Congress to intimate their intentions to the secretary before the end of March, 1881.

All communications respecting the Congress should be addressed to William MacCormac, Esq., Hon. Secretary-General, 13, Harley-street, London, W.

The following is the list of officers:—

President of the Congress.—Sir James Paget, Bart., LL.D., D.C.L., F.R.S.

Vice-Presidents of the Congress.—President of Royal College of Physicians, London; Presidents of Royal Colleges of Surgeons of England, Ireland, and Edinburgh; President of Royal College of Physicians of Edinburgh, and of the King and Queen's College of Physicians, and Faculty of Physicians and Surgeons, Glasgow; Master of Society of Apothecaries, London, Governor of Apothecaries' Hall, Ireland; Professor Acland; Sir George Burrows, Bart.; G. Busk, Esq.; Dr. W. B. Carpenter; Sir Robert Christison, Bart.; Luther Holden, Esq.; Sir J. Hooker; Dr. Hudson; Professor Huxley; Sir W. Jenner, Bart.; Thomas Keith, Esq.; Professor Lister; Robert MacDonnell, Esq.; Professor Owen; Professor George Paget; Professor Burdon Sanderson; Professor Spence; Professor Allen Thomson; Sir Thomas Watson, Bart.; Spencer Wells, Esq.

Section I., ANATOMY.—*President:* Prof. Flower, F.R.S. *Vice-Presidents:* Prof. Macalister, M.D., Dublin; Prof. Rolleston, M.D., F.R.S., Oxford; Prof. Turner, F.R.S., Edinburgh. *Secretary:* Prof. Thane.

Section II., PHYSIOLOGY.—*President:* Prof. Michael Foster, F.R.S., Cambridge. *Vice-Presidents:* Dr. F. W. Pavy, F.R.S.; Prof. John Mallet Purser, M.D., Dublin; Prof. William Rutherford, M.D., F.R.S., Edinburgh. *Secretaries:* Dr. C. S. Roy; Prof. Gerald Yeo.

Section III., PATHOLOGY AND MORBID ANATOMY.—*President:* Dr. Samuel Wilks, F.R.S. *Vice-Presidents:* Dr. John Syer Bristowe; Jonathan Hutchinson, Esq.; Professor Sanders, M.D., F.R.S.E., Edinburgh. *Secretaries:* Dr. J. F. Payne; Marcus Beck, Esq., M.S.

Section IV., MEDICINE.—*President:* Sir William Gull, Bart., M.D., F.R.S. *Vice-Presidents:* Prof. Gairdner, M.D., Glasgow; Dr. Quain, F.R.S.; Dr. William Roberts, M.D., F.R.S., Manchester. *Secretaries:* Dr. Duckworth; Dr. W. M. Ord.

Section V., SURGERY.—*President:* John Eric Erichsen, Esq., F.R.S. *Vice-Presidents:* Professor E. H. Bennett, M.B., Dublin; Professor Humphry, M.D., F.R.S., Cambridge; W. S. Savory, Esq., F.R.S. *Secretaries:* H. Greenway Howse, Esq.; Thomas Smith, Esq.

Section VI., OBSTETRIC MEDICINE AND SURGERY.—*President:* Dr. McClintock, LL.D., Dublin. *Vice-Presidents:* Dr. Barnes; Dr. Matthews Duncan, LL.D., F.R.S.E.; Dr. Priestley. *Secretaries:* Dr. Galabin; Dr. John Williams.

Section VII., DISEASES OF CHILDREN.—*President:* Dr. West. *Vice-Presidents:* Dr. Gee; Timothy Holmes, Esq. *Secretaries:* Dr. Donkin; R. W. Parker, Esq.

Section VIII., MENTAL DISEASES.—*President:* Dr. Lockhart Robertson. *Vice-Presidents:* Dr. Crichton Browne, F.R.S.E.; Dr. Maudsley. *Secretaries:* Dr. Gasquet; Dr. Savage.

Section IX., OPHTHALMOLOGY.—*President:* William Bowman, Esq., F.R.S. *Vice-Presidents:* G. Critchett, Esq.; Henry Power, Esq., M.B.; Dr. Argyle Robertson, F.R.S.E., Edinburgh. *Secretaries:* Dr. W. A. Brailey; E. Nettleship, Esq.

Section X., DISEASES OF THE EAR.—*President:* William B. Dalby, Esq. *Vice-Presidents:* Dr. Cassells, Glasgow; Dr. Fitzgerald, Dublin. *Secretaries:* Dr. Urban Pritchard; Dr. Laidlaw Purves.

Section XI., DISEASES OF THE SKIN.—*President:* Erasmus Wilson, Esq., F.R.S. *Vice-Presidents:* Dr. Cheadle; Dr. R. Living. *Secretaries:* Dr. Cavafy; Dr. Thin.

Section XII., DISEASES OF THE TEETH.—*President:* Edwin Saunders, Esq. *Vice-Presidents:* John Tomes, Esq., F.R.S.; Charles Spense Bate, Esq., F.R.S. *Secretary:* C. Tomes, Esq.

Section XIII., STATE MEDICINE.—*President:* John Simon, Esq., C.B., F.R.S. *Vice-Presidents:* Dr. George Buchanan; Professor de Chaumont, F.R.S.; Dr. Douglas MacLagan, F.R.S.E., Edinburgh; J. Netten Radcliffe, Esq. *Secretaries:* Professor Corfield, M.D.; Dr. Thorne Thorne.

Section XIV., MILITARY SURGERY AND MEDICINE.—*President:* Surgeon-General Professor Longmore, C.B. *Vice-Presidents:* Sir William Muir, M.D., K.C.B., Director-General Army Med. Dep.; Sir Joseph Fayrer, M.D.,

K.C.S.I., F.R.S., India Office; Dr. J. W. Reid, Director-General Med. Dep. of Navy. *Secretaries:* Surgeon A. B. R. Myers, Coldstream Guards; Surgeon-Major Sandford Moore, Aldershot.

Section XV., MATERIA MEDICA AND PHARMACOLOGY.—*President:* Professor T. R. Fraser, M.D., F.R.S., Edinburgh. *Vice-Presidents:* Dr. Lauder Brunton, F.R.S.; Professor Sydney Ringer. *Secretaries:* Dr. E. B. Baxter; Dr. F. T. Roberts.

MUSEUM OF SCIENTIFIC APPARATUS AND MATERIA MEDICA.—*Museum Committee:* Jonathan Hutchinson, Esq., *Chairman;* Waren Tay, Esq.; C. Stewart, Esq.; Dr. G. V. Poore; Dr. F. Macnamara; J. F. Goodhart, Esq.

Reception Committee: Prescott Hewett, Esq., *Chairman;* Sir Trevor Lawrence, Bart., M.P.; Sir Henry Thompson; Dr. Farquharson, M.P.; Dr. Lyons, M.P.; J. H. Puleston, Esq., M.P.; Dr. A. Vintras; Dr. Lionel Beale; Dr. Andrew Clark; Dr. Philip Frank; J. Cooper Foster, Esq.; Ernest Hart, Esq.; Dr. George Johnston; John Marshall, Esq.; Dr. W. O. Priestley; Dr. Owen Rees. *Secretaries:* Dr. Samuel West; Dr. Seymour Sharkey.

Executive Committee.—Dr. Risdon Bennett, LL.D., F.R.S., Pres. Roy. Coll. Phys., London, *Chairman;* Sir W. Jenner, Bart., M.D., K.C.B., D.C.L., F.R.S.; Sir James Paget, Bart., LL.D., D.C.L., F.R.S.; Sir William Gull, M.D., F.R.S.; Luther Holden Esq.; Professor J. Lister, D.C.L., F.R.S.; Dr. H. A. Pitman; W. Bowman, Esq., F.R.S.; Dr. Sieveking; Dr. Herman Weber; Jonathan Hutchinson, Esq., Dr. J. Matthews Duncan, LL.D., F.R.S.; Prescott Hewett, Esq., F.R.S.; Dr. Andrew Clark; A. O. Mackellar, Esq.; Dr. A. B. Shepherd, Dr. P. H. Pye-Smith, W. MacCormac, Esq.

Correspondence.

"Audi alteram partem."

ON THE EXCISION OF OBSTRUCTION AT THE NECK OF THE BLADDER.

To the Editor of THE LANCET.

SIR,—Will you kindly permit me, through the columns of your magazine, to give publicity to the few comments I wish to make upon the subject of Dr. Mercier's operation of excision of prostatic valvules, to which, I think—for brevity's sake, if for no other reason—the name of "Prostatectomy" should be given, while, for the same reason, "Prostatotomy" may be applied to incision of the valvules. I now broach this question on account of the appearance of a letter by Mr. G. Buckston Browne in THE LANCET of June 5th, 1880, p. 896.

Mr. Browne begins his communication by challenging Mr. Teevan's statements concerning Mercier's operation; but as Mr. Teevan is well able to make good all his utterances, I shall leave him to fight his own battle, feeling confident that he will be victorious, for I am sure he is right in all that he has said about Dr. Mercier and prostatectomy. Dr. Mercier, however, does not know English; he is an aged man, needing rest of mind and body; and besides, he is now at his country-house to recruit his shattered health, and may not be aware of the present attack upon his good name and fame.

It is as a friend and disciple of Dr. Mercier, and as a lover of fair-play, that I write to refute the statements of Mr. Browne regarding prostatectomy. It seems to me that Mr. Browne has been hasty in condemning this operation, as it does not appear in his letter that he has the warrant of actual experience and observation for his denunciation; on the contrary, he acknowledges that the operation has never been performed in England. His views and objections are therefore purely theoretical, and must fall before Mercier's facts. If Mr. Browne will for several years carefully study the four volumes pertinent to the subject written by Dr. Mercier, make numerous trials of prostatectomy and prostatectomy upon the cadaver, and then perform these operations upon the living, and wait at least a year for the final result, he may possibly come to the point of advocating them as strongly as I do; if not, then it is to be hoped that he will propose some-

thing better, but until that time his condemnation should go for nothing. I do not think it fair to say, of a gentleman of Mr. Teevan's erudition, that he does not "appear to have consulted the chief English literature" of the subject upon which he has lectured so well. I believe Mr. Teevan to be thoroughly familiar with all the literature—good, bad, and indifferent—of the subjects which he treats, otherwise he never would have been appointed Lettsomian Lecturer by the learned body which has the power of conferring that honour.

The statement that the "operation is rarely if ever employed by more than one surgeon in Paris, and that many years ago, and now abandoned there," is not correct. It has been performed by other surgeons in Paris within a few years, and has never been abandoned, at least by Dr. Mercier. It has been very badly done by some surgeons, who, not understanding it, never should have undertaken it. They have abandoned it, and wisely too. All those who refuse to study the operation as it should be studied will either execute it badly or refuse to perform it. In bad hands it is worse than useless; in good hands it is eminently successful. Mr. Teevan has doubtless looked carefully into all the facts connected with prostatectomy, and deserves to be thanked for calling the attention of a learned Society to so important a subject, about which one-third of mankind after the age of fifty is so deeply concerned.

To the best of my knowledge and belief I declare that Dr. Mercier has performed his operation on upwards of four hundred patients. Hæmorrhage has been more frequent and abundant in incision than in excision, but has never been fatal. He considers it as merely a bugbear; consequently the Italian method is unnecessary. In a prostatectomy followed by prostatotomy (the excision and incision giving a depth of two centimetres) performed by me a week ago the patient lost half an ounce of blood, and the urine was tinged with blood for two days only. He sat up half of the day following the operation, and was up and dressed every day thereafter. He has not had a bad symptom. I may say the same of another patient sixty-seven years of age—operated upon two months ago—who sat up in bed in a few days and was up and dressed in a week. My oldest patient was seventy-six, was operated upon nearly two years ago, and is now in fair health and better of his urinary trouble than he had been for several years before.

The operation which I performed a week ago was done with an improved instrument, a modification which I made of Mercier's first excisor. I have within a few days ordered a new prostatectome, whose male blade will be much more easily opened to seize the valve than Mercier's present excisor, and with which one centimetre of the depth of the valve can at once be removed.

I have several new cases under preparation for prostatectomy, and see no reason why I should not continue to perform the operation. After my results have become generally known, this operation will, I think, make great progress in America. May it thrive in England, and may Mr. Browne be the first in Great Britain to say of it, in the language of Chaussier and Percy when they reported upon lithotomy, that it is "equally glorious to French surgery, honourable to its author, and consoling to humanity."

I am, Sir, very respectfully yours,

JOHN W. S. GOULEY, M.D.,

Professor of diseases of the genito-urinary system in the
Medical Department of the University of the
City of New York, Surgeon to
Bellevue Hospital, &c.

New York, June 22nd, 1880.

TEACHING AND EXAMINATIONS IN THE UNIVERSITY OF EDINBURGH.

To the Editor of THE LANCET.

SIR,—In the course of a pleading in favour of the one-portal system, you have given publicity to statements regarding the teaching of, and examining in practice of, physic in the University which are quite erroneous, and I shall be obliged if you will insert this letter, and give the same publicity to the contradiction as you have accorded to the assertion.

I have never objected to any question put by an assessor in any examination, and the area of examination has never been restricted. I cannot imagine the possibility of my objecting to any question put by such examiners as those with whom I have been associated—Dr. Dyce Duckworth of St.

Bartholomew's Hospital, and Dr. Duffin of King's College—with both of whom I have enjoyed the most complete accord, and for whose depth of knowledge and precision in examining I have the highest admiration.

As to my course of lectures, I beg to refer you to the University Calendar, p. 82, from which I extract the following paragraph:—"It is intended that each course shall be, so far as possible, complete; but that while the general principles (included in Part 1) shall be fully discussed each session, the diseases of individual systems (included in Part 2) shall be taken up in different order year by year, and certain systems selected for more minute consideration."

It must be obvious to any one acquainted with what you justly call the "great theme" of practice of physic that no one can at the present day give a satisfactory course in a single winter session. I am personally of opinion that the Universities, and even the General Medical Council, should require two courses on such a subject. But considering that in the meantime only one course is required, I have uniformly striven to condense as much as possible, and each session include some account, at least, of the diseases of each physiological system. I venture to think that the course which you have selected for criticism would be found, on inquiry, one of the most complete delivered anywhere in a single session.—I have the honour to be, Sir,

Your obedient servant,

T. GRAINGER STEWART.

July 12th, 1880.

** We gladly insert Dr. Grainger Stewart's letter. Taken in connexion with Dr. Duckworth's letter and others which we publish, it makes it pretty clear that if the Edinburgh University student is not prepared for his examinations in the Practice of Medicine, it is not the fault of his teachers or their modes of teaching. If Dr. Stewart will read our remarks over again, he will see that while giving publicity to the "notion" of our correspondent as having possibly some basis in truth and raising one or two interesting questions, we expressed our belief that he was in actual error in his main suggestion, that an assessor in examinations was hindered in his choice of subjects by the professor. The case is very much as we surmised. Dr. Stewart's exposition of the Practice of Medicine in its completeness can only be got by a student attending two courses. Further proof that Dr. Stewart does not merely repeat himself is found in the large classes of students who attend two courses of his lectures, though only required to attend one. We agree with Dr. Stewart that it is scarcely possible in a single winter session to cover the wide field of practice of physic. But we think that the professor should not only overtake in each session the diseases "of each physiological system," but should emphasise the common and serious diseases of each chief organ, even if at the expense of some incompleteness of detail and system.—ED. L.

To the Editor of THE LANCET.

SIR,—Under the heading of "Teaching and Examinations in the University of Edinburgh," you make a statement which I feel it incumbent upon me immediately to correct. You there say "an assessor in the University of Edinburgh, examining in the practice of physic, put a very proper and straightforward question, which was objected to by the examining professor on the ground that the subject had not been discussed by him in the course of lectures which the student had attended."

Being the assessor referred to, I beg emphatically to deny that any restriction was placed on the subject-matter at my disposal. It was from the first clearly understood that the range of my examinations was not to be in any way limited by the group of subjects which Professor Grainger Stewart had touched upon during the preceding winter. Far from that, Professor Stewart expressly desired me to examine upon any and every subject that might legitimately be included as "practice of physic." "The men are presumed to have prepared these subjects, whether they have heard them lectured upon or not." Professor Stewart never even gave me a list of the subjects that had formed part of his

previous winter course, and I am at this moment ignorant of what his curriculum comprised. As a matter of fact, I drew my questions from the whole range of the practice of physic, and was extremely gratified at the good "all round" standard of excellence they elicited.

I am, Sir, your obedient servant,

ALFRED B. DUFFIN, M.D.,

Physician to King's College Hospital.

King's College, London, July 12th, 1880.

To the Editor of THE LANCET.

SIR,—I read with regret your remarks on "Teaching and Examinations in the University of Edinburgh," and as first senior medallist of the class of Practice of Physic, I have been asked to represent the class; and so I beg of you that you will do the Professor of the Practice of Physic the justice of publishing the following:—

The whole range of medicine cannot possibly be satisfactorily discussed in a hundred lectures of one hour each, but one set of systems is fully treated of in alternate sessions—the remaining systems not being neglected, but so dealt with as actually to give the student the most important points, and guide him to the rest. Consequently in no session is any system left untouched; and if one of the systems receiving a minor share of attention in any year happens to be the respiratory system, certainly such a disease as pneumonia would in any case be fully studied. In point of fact, I have attended the class of Professor Grainger Stewart during the past two sessions, and, after comparing the notes taken during these courses, I can state definitely and precisely that your fears of a necessarily imperfect education of the Edinburgh University medical student are entirely groundless. At the opening days of the session Professor Stewart distinctly told us that in the systematic course he would not be able to go over the whole subject with us, but said what he would do, and recommended the text-books necessary to get up the rest. Moreover, the Professor in his clinical lectures and bedside teachings constantly endeavours to illustrate more fully the imperfectly treated subjects; and since every student must attend the clinical lectures, and most students attend his clinics in the Infirmary at least one session, I am decidedly of opinion that if any student be imperfectly educated the shortcomings are not from the side of Professor Grainger Stewart.

I am, Sir, yours obediently,

Edinburgh, July 13th, 1880.

ANDERSON STUART.

To the Editor of THE LANCET.

SIR,—In your issue of the 10th inst. I find attention called to the conduct of the Examinations in Practice of Physic at Edinburgh.

Inasmuch as the alleged circumstances in your paragraph must refer either to Dr. Duffin, of King's College Hospital, or to myself, I am constrained, for my part, to offer the most unqualified denial to them.

After holding office for five years as a University Examiner, in association both with the late and the present Professors, I am free to state that I have no recollection of having been interfered with on any occasion in the course of my duties. I acted in the most strict and impartial spirit, all the candidates being strangers to me, and I certainly covered the whole field of subjects.

Not knowing the members of the Professor's class from those who had attended the lectures of other teachers, I could, of course, make no distinction in framing my questions; and, I may add, that I was equally ignorant of the particular subjects developed, or less fully treated of, by the Professor in his previous prelections.

So far as I am concerned, I am content to give a simple denial to your correspondent's assertions, leaving it to those who must, in this matter, have most knowledge—the numerous body of gentlemen whom I had the honour to examine, and to those who know me best to give me credit, or the reverse, for fairness and independence as an examiner.

Looking back upon my term of office, I may state that I could no more conceive of such interference, as alleged on the part of the Professor, than I could contemplate my own subserviency in paying any heed to it.

I am, Sir, your obedient servant,

DYCE DUCKWORTH.

Grafton-street, Piccadilly, July 12th, 1880.

HOSPITAL STATISTICS OF ALCOHOLIC STIMULATION.

To the Editor of THE LANCET.

SIR,—Nearly twenty years ago I came to the conclusion that a careful analysis of the wine, spirit, and malt liquor roll of every hospital in the kingdom, with reference to the average daily quantities administered to each patient, would be a very important and valuable contribution to hospital statistics, if set forth in such a way as to show the limits of variation depending upon the practice of individuals in medical, surgical, fever wards, &c., over determinate periods, as, e.g., from month to month, from year to year, &c. In a volume entitled "Clinical Medicine," published in 1862, I submitted a statement of this kind bearing on my own practice for five years in the Royal Infirmary of Edinburgh; and in relation to fever, similar returns were afterwards published in even greater detail by myself and by Dr. Russell, indicating in daily averages the amount of alcoholic stimulants used by each patient in our respective fever wards in the treatment of typhus. These returns were not without an effect on medical opinion; but their usefulness would have been greatly increased had the method indicated in them been generally followed. And now that you are again directing attention to the subject, I would take the opportunity of urging that in every public hospital such returns should be regularly submitted, and an analysis of them published in the annual reports. The rough aggregates usually given as representing the practice of individual hospitals are of comparatively small value. If some one having authority would promulgate a blank schedule with the particulars required, it might be adopted, after due consideration, by every hospital in the kingdom without further delay.

I remain, Sir, yours truly,

Glasgow, July 13th, 1880.

W. T. GAIRDNER.

"ARMY MEDICAL REPORT FOR 1878."

To the Editor of THE LANCET.

SIR,—My attention has just been called to a passage in the review of the Army Medical Report for 1878 in your issue of the 10th inst., in which you comment on the absence of any contribution from the medical division of this hospital. Will you permit me to say that I am not responsible for the omission. A very interesting, and, as it appeared to me, instructive report, was drawn up for the Blue Book at my request by Dr. Veale, Assistant Professor of Military Medicine in the Army Medical School, on the causes of fever under treatment in this hospital from Cyprus, Malta, and Gibraltar.

The interest of this report, to my mind, consisted in the fact that it established on a sure scientific basis the specific difference between the fevers of Cyprus and those of Malta and Gibraltar. This report was forwarded, through the usual official channel, to the authorities for publication. The executive medical officers of the medical division of this hospital are in no way responsible for its non-appearance.

I am, Sir, faithfully yours,

N. C. MACLEAN, M.D.,

Professor of Military Medicine, Army Medical School.

Royal Victoria Hospital, Netley,

July 13th, 1880.

THE VACCINATION ACTS.

To the Editor of THE LANCET.

SIR,—As a general practitioner, I think, with you, there is much to be said for the Legislature limiting the multiplicity of fines of parents for not having their children vaccinated. I object to make fools and fanatics into martyrs by fines and imprisonments, and to have the greatest discovery of medicine and the pure benevolence of the profession disparaged and misrepresented in the process. For my part, I should object to vaccinate a child brought to me by Dr. Brewer's policeman, and not by its parents. The limited fines will sufficiently indicate law and duty and civilisation. They will suffice to secure the vaccination of all children whose parents are not incurable fools, and, with all respect to Mr. Carlyle, these are not so very large a proportion of

the human race. The unlimited fines do no more than this, and they do great harm by creating agitation and sympathy, for which there will be no room under the amended Act.

The medical profession has acted with pure benevolence and unselfishness in this matter. It has nothing to gain but credit, not even money, from neglected or despised vaccination. Small-pox is a disease on which good-sizeable medical bills may be founded, very different from the paltry fees got for vaccination.

I am by no means, however, disposed to let the fools and fanatics off too easily. I would suggest that under the new Act fines for exposure of small-pox should be increased, and that medical men be empowered to charge double fees for attending a disease so disgusting and so preventable. Only yesterday a strange servant-girl walked into my house, covered with small-pox pustules, after being at a chemist's, and perhaps another medical man's. This is surely a great nuisance, against which the profession has a right to claim some protection. To have one's servants and children recklessly and needlessly exposed to so preventable a disease, is a grievance of which we have a right to complain. In other words, if the non-vaccination fine is to be mitigated, for which I think there is much to be said, I maintain that those who deliberately court small-pox should be regarded as having cultivated personal liberty in a most selfish and offensive way, and should be made to pay for it, in the general reprobation of sensible people, in severe isolation, and in heavy medical taxes. It is reasonable, too, in this connexion, to consider the propriety of a law requiring revaccination. I have, you will see, more faith in law and less in fines than some of my medical brethren. Medical men will, in the course of time, be better appreciated for their strong and unselfish advocacy of vaccination, and the disease of small-pox will come to be rightly regarded as at once a crime, a disgrace, and a punishment.—I am, Sir, your obedient servant,

July 12th, 1880.

A GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—Readers of the *Echo* on Thursday and Friday evenings of last week must have been somewhat surprised to see that a petition had been presented from the British Medical Association, signed by 2000 medical men, "against vaccination." The facts of the case are, that I had the honour of presenting a petition from the Committee of Council of the British Medical Association against the "Vaccination Acts Amendment Bill"; that this having been incorrectly described by the *Echo*, the Editor of that paper has ignored my twice repeated request to make that explanation which I am now glad to have the opportunity of laying before your readers.

Faithfully yours,

R. FARQUHARSON.

July 14th, 1880.

H.M. PRISON, COLDBATH-FIELDS.

To the Editor of THE LANCET.

SIR,—You have been grossly misinformed as to the mortality in this prison; the fact being that only two deaths have occurred from January 31st to this date—namely, one from acute pneumonia on the 24th of June and a case of suicide by strangulation on the 25th of June, our daily average number of prisoners being about 1500.

I am, Sir, faithfully yours,

W. SMILES, M.D., Surgeon.

July 12th, 1880.

* * We are pleased to receive Dr. Smiles's correction with regard to the general health and mortality among the prisoners at the Coldbath-Fields Prison. Still it does not affect the question at issue, which is, that since the introduction of the new dietary scale there have been three deaths, *all among short-termed prisoners*, on whom the new scale presses with undue severity. The death of the prisoner Nolan, we have always maintained, was never satisfactorily explained. And the circumstances attending the two recent deaths mentioned by Dr. Smiles require to be more fully detailed before the public conscience can be satisfied that the fatal issue in both cases was not hastened, if not actually induced, by the depression caused by the severity of the dietary.—ED. L.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Friday, the 9th inst., a petition from the British Medical Association was presented against the Government Bill for the Abolition of Multiple Penalties for Non-vaccination. Curiously enough, this petition was reported in an evening paper as "against vaccination." Other petitions against the Bill were presented from London, Leeds, and Manchester.—The twenty-ninth Report of the Inspectors of Lunatic Asylums in Ireland was presented.—A short discussion took place on the appointment of the Select Committee on Contagious Diseases Acts. Mr. Childers urged, in reply to objectors, that there was still time to get through one branch of the subject, in continuation of the labours of the previous Committee, and promised to consider some suggested additions to the number of the Committee. The Government nomination was then agreed to, as follows:—Mr. Cavendish Bentinck, Mr. Stansfeld, Colonel Alexander, Sir Harcourt Johnstone, Viscount Crichton, Mr. Burt, Mr. O'Shaughnessy, Mr. Osborne Morgan, Mr. Brassey, Mr. Cobbold, General Burnaby, Sir Henry Wolff, Mr. Ernest Noel, Colonel Digby, and Mr. William Fowler.

On Monday Mr. Dodson replied to Mr. Cowen that the regulations for the prevention of the overcrowding of canal boats rested with the local authorities to carry out, and no representation had been made that increased powers were necessary. There was considerable difficulty in dealing with the occupants of gipsy tents and other movable dwellings, but the Local Government Board would endeavour to deal with them, in the way of sanitary regulations, at a favourable opportunity.—Mr. Hastings inquired when the National Vaccine Establishment would begin to supply calf vaccine. Mr. Dodson was sorry he was unable to give a definite answer. The Local Government Board were making inquiries to ascertain what would be the best arrangement in order to secure an adequate and constant supply; but inasmuch as the Department would be answerable for the quality of the lymph the greatest care was required, and therefore, with every desire to push the matter on as rapidly as possible, he was afraid some further time must elapse before they would be in a position to commence the requisite supply. Sir H. D. Wolff put a series of questions as to the shipping of lunatics to England by the Indian military authorities, and referred to two cases in which such persons had been quartered on the rates at Portsmouth. Mr. Childers said the soldier's wife and the boy referred to in the question were taken to the union, as alleged, but stoppages were made on the highest scale from the pay of the husband and the father respectively towards their maintenance. It was not within his province to say whether the Indian authorities were justified in sending them home, but in the case of the boy, who had been in an asylum in India, the medical officer there reported, that the climate was dangerous to him. He had asked the Secretary for India to make inquiry in the matter. Sir H. D. Wolff gave notice that he would ask for the correspondence relating to cases of Indian lunatics landed at the port of London. Mr. Forster, in reply to questions from the Irish members, promised to lay on the table a report from Dr. Nixon, a temporary medical inspector who had been sent into the fever districts. Fever prevailed chiefly in the union of Swinford, and although some additional cases had been reported within the last few days, he had reason to believe that the disease was on the decline. The last return from Swinford stated that there were 96 fever patients in the infirmary. The vice-guardians advertised for a second doctor, but no one answered the advertisement. They had now, however, succeeded in obtaining the services of one from Dublin, and also one or two trained nurses, and an ambulance. The sanitary condition of the places where the fever most prevailed was deplorable, and when the fever once got a hold it was very difficult to check it. The difficulty was much increased by the fear which the people had of infectious disease, and their unwillingness to acknowledge its existence in their houses. Mr. O'Connor Power inquired whether the right honourable gentleman had given any special instructions with a view to improving the sanitary arrangements of which he complained. Mr. Forster was sorry to say that he referred mainly to the condition of the cabins; and these defects were not very easily removed. The guardians were doing what they could, but it was not an easy matter to assuage the condition of a large

population. The overcrowded and bad condition of the cabins made the fever spread very rapidly. Mr. Parnell said it appeared there was an entire want of preparation for the outbreak of fever at Swinford. Were steps being taken to be in readiness in other unions? Mr. Forster replied that the Local Government Board were taking steps. Boards of guardians had been requested to provide ambulances. Something must be left to local government, and it was hoped the guardians would do their duty, as in a great many cases they were doing. What had happened at Swinford was likely to be a warning to other boards.

On Tuesday, in reply to Mr. Elliot, Mr. Peel stated that in August, 1879, the ambulance classes established under the auspices of the Order of St. John of Jerusalem were transferred to certain divisional surgeons of the metropolitan police, who voluntarily undertook the duty of instruction. More classes would be held in October next, and all necessary facilities would be given. The course of instruction embraced the treatment of persons in a state of insensibility, casualties in the streets, and other practical matters connected with ambulance work, and rendering the first aid to the sick or injured. The police, who had hitherto attended the classes, were reported by Sir E. Henderson to have evinced great interest in the course and marked ability to grasp the subjects taught.

On Wednesday, petitions against the Vaccination Acts Amendment Bill were presented from the Royal College of Surgeons, Ireland, from the Forfarshire Medical Association, and from Cambridge and Prescott.—The second reading of Mr. Dillwyn's Lunacy Law Amendment Bill was again deferred for a week.—Nearly all the time of the House is now occupied by Irish debates. Mr. Parnell, as leader of the "active party," has too much to do to attend Committees, and he was to-day discharged from further attendance on the London Water Supply Committee; Mr. Maurice Brooks, one of the moderate Irish members, being appointed in his place.—The Births and Deaths Registration (Ireland) Bill was read the third time and passed.

The Vaccination Acts Amendment Bill stood for second reading on Thursday evening, but inasmuch as the Irish Disturbance, Budget, and Hares and Rabbits Bills were before it, a further adjournment was, of course, inevitable.—The same remark applies to the completion of the Select Committee on the Contagious Diseases Acts, which has been on the Order Book for some days. Mr. Childers proposes to substitute Mr. Massey for Mr. Brassey, who was put on the list by mistake, and Mr. Puleston will move that Dr. Farquharson be added to the Committee, which Sir Harcourt Johnstone will oppose.—Sir H. D. Wolff put another question as to the practice of sending pauper lunatics home from India, and the Marquis of Hartington said he was making inquiry into the matter.—Mr. Hanbury Tracy had a question on the paper as to compensation for officers for injuries sustained on torpedo service, but it was deferred.—Mr. Storer interrogated the Home Secretary with regard to the infliction of fines, amounting to £9, for ear-marking cattle at Bedale, in Yorkshire. Sir W. Harcourt postponed the answer until he had had time to obtain information, and elicited a loud cheer by suggesting that all complaints against magistrates should first be addressed to him privately at the Home Office.—Dr. Lyons asked the Chief Secretary to the Lord Lieutenant of Ireland whether it is true that trained nurses skilled in the management of fever have been supplied by the Hardwicke Fever Hospital, Dublin, to take charge of the fever cases at Swinford at the request of the Local Government Board, Ireland, and whether it is true that up to the present date there has been no report of the occurrence of purpura hæmorrhagica as a complication of the fever now prevailing in the west of Ireland. Mr. Forster replied in the affirmative to both questions. Two trained nurses had been secured, and the complication that was represented by two words which he would not venture to pronounce had not yet appeared. The right honourable gentleman added that there was reason to hope, from information he had received, that the fever was abating. The guardians had been instructed to obtain the services of nurses, where required, and to take such steps as might be possible to put the people's houses in a better sanitary condition.

QUEEN'S UNIVERSITY, IRELAND.—John T. Collier, M.D., passed the examination for the degree of Master in Surgery, but was absent at the conferring of the degrees.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the last meeting of the Council the following Member was elected a Fellow of the College:—

Haward, Edwin, M.D. Edin., M.R.C.P. Lond., Harley-street; diploma of membership dated Feb. 3rd, 1887.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 9th, 12th, 13th, and 14th inst.:—

Ernest A. White, Ernest H. Simmons, Henry W. Hooper, John U. Bolton, Sidney Davies, Harry A. Francis, John L. Stretton, and John H. Harris, St. Bartholomew's Hospital; William Wilson, Samuel B. A. Edsall, Albert Green, William D. Snallpiece, Edward S. Tresidder, Albert S. Topham, Edward W. Roberts, Arthur L. Fireman, Edward O. Newland, Alfred M. Sutton, Francis G. F. Chittenden, and John H. Greenway, Guy's Hospital; Cecil M. Hendriks, Alexander I. Grant, Charles O. Fowler, Harry Harlock, Henry J. Harries, Edward H. Tenison, Percy F. Money, Edward O. Croft, Walter F. Scott, James W. Draper, Mohamed J. Khan, William H. Horsman, Robert W. Watson, Wilmot H. Evans, William H. Tomlins, and Charles L. Ashby, University College; George Greenwood, John H. Williams, Charles M. Chadwick, William A. Norry, Charles J. Dabbs, and B. Aslamian, London Hospital; Montagu W. Williams and William Davies, Middlesex Hospital; Thomas E. Rogers, Charing-cross Hospital; Mark Style, St. Mary's Hospital; James E. Kershaw and Frederick W. S. Stone, St. Thomas's Hospital; George E. Bloxam, St. George's Hospital; Richard H. Botham, King's College; Edward T. Collins, Middlesex Hospital; James F. Saunders, Guy's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on July 8th:—

Knight, Alfred Osborne, Tewkesbury, Gloucestershire. Villanueva, Francis Horton, Southampton-row.

The following gentlemen also on the same day passed the Primary Professional Examination:—

K. R. Divecha, Grant Medical College, Bombay; Daniel Thurston, London Hospital; Gilbert Thomas Smith, St. Bartholomew's Hospital; John Cornelius Garmon, Edinburgh Infirmary.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following gentleman was admitted a Fellow of the College on the 3rd inst.:—

Hamilton, John, L.R.C.P. Edin., Swadlincote, Burton-on-Trent.

DR. BUZZARD has been elected an Honorary Fellow of King's College, London.

JAMES RUSSELL, M.D., has been placed on the Commission of the Peace for Birmingham.

ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.—A portrait of the late Dr. Ramsford, Senior Surgeon to this institution, has been presented by a near relative.

At the quarterly meeting on the 14th instant of the Directors of the Naval Medical Supplemental Fund, Dr. H. J. Domville, C.B., M.D., Inspector General, in the chair, the sum of £65 was distributed among the several applicants.

DUBLIN ORTHOPÆDIC HOSPITAL.—Her Excellency the Countess Cowper visited this institution last week, and, expressing herself much pleased with the manner in which it was conducted, distributed a quantity of choice flowers amongst the inmates.

VACCINATION GRANTS.—The following gentlemen have received Government grants for efficient vaccination in their respective districts:—Mr. William Smith, Redditch District of the Bromsgrove Union (third time); Mr. Beaven Rake, No. 2 District of the Fordingbridge Union (third time); Dr. W. Hoffmeister of Cowes, Isle of White District (third time in succession).

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. Thomas Gray, of Willow Bank, bequeathed £100 to the General Infirmary; £100 to the Hospital for Women, and £50 to the Public Hospital and Dispensary, all at Sheffield. The Middlesex Hospital has received £210, the amount realised by a performance of the Inseparables Amateur Dramatic Club at the St. James's Theatre. Mr. Henry Levy Keeling, of Albany-terrace, Regent's-park, bequeathed £100 each to the London Hospital and the Metropolitan Free Hospital. Mr. Charles Montague Chester bequeathed £100 to the Samaritan Free Hospital for Women and Children. The Cordwainers' Company have given a third twenty guineas to the Asylum for Idiots, Earlswood, near Redhill.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ANNINGSON, B., M.D., M.R.C.S.E., has been re-elected Medical Officer of Health for the Chesterston District.
 BATTYE, J. H., M.D., M.R.C.S.E., L.R.C.P.L., has been appointed Third Attending Medical Officer to the Provident Medical Institution, Picnic-road, vice J. J. Sewell, retired.
 BRISCOE, W. T., A.B., M.B., & M.Ch., has been reappointed Medical Officer of Health for the Chippenham Union District.
 CONSTABLE, J., M.D., C.M., has been appointed Medical Officer and Vaccinator for the Parish of Logie, Fifeshire, vice Dr. J. W. R. Mackie, deceased.
 DUNLOP, J., M.B., C.M., has been appointed Assistant Medical Officer to the Woodilee Asylum, Lenzie, near Glasgow.
 EDMOND, G. M., M.A., M.D., has been appointed Medical Officer of Health for Dunottar, at a salary of £10 per annum, vice J. T. Thom, M.D., deceased.
 GOUDE, H., F.R.C.S.Ed., M.R.C.S.E., L.S.A.L., has been appointed Resident Surgeon to the Small-pox and Vaccination Hospital, Highgate-hill, vice F. W. Strugnell, resigned.
 HARRISON, J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health to the Braintree Union, for one year.
 HASLET, J. C., M.D., M.Ch., L.A.H.D., has been appointed an Honorary Physician to the Ulster Hospital for Children, Belfast.
 JONES, J. R., M.B., L.R.C.P.L., has been appointed House-Physician to the Hospital for Women, Soho-square, vice J. H. H. Bottrell.
 JONES, R. R., M.R.C.S.E., has been elected a Junior House-Surgeon to the Newcastle Infirmary, vice Dr. Dodd, resigned.
 MORRIS, J. W., L.R.C.P.L., M.R.C.S.E., has been re-elected Medical Officer for the Llannon District.
 SPOFFORTH, J., M.R.C.S.E., L.R.C.P., has been elected Honorary Surgeon to the Kidderminster Infirmary.
 WILLIAMS, W. R., L.R.C.P.L., M.R.C.S.E., has been appointed Senior House-Surgeon to the Wigan Royal Infirmary.

Births, Marriages, and Deaths.

BIRTHS.

EDIS.—On the 13th inst., at 22, Wimpole-street, the wife of W. Edis, M.D., F.R.C.P., of twins (both girls).
 HILL.—On the 7th inst., at Earl's Court-road, the wife of T. Wood Hill, Surgeon, of a daughter.
 HOPKINS.—On the 7th inst., at Kingswear, Sutton, Surrey, the wife of Surgeon-Major Nathaniel Hopkins, I.M.D., of a daughter.
 MADELEY.—On the 4th inst., at The Quadrant, Coventry, the wife of Staff-Surgeon G. H. Madeley, H.M.S. *Albatross*, of a son.
 PARSONS.—On the 6th inst., at 13, Whitworth-road, South Norwood, the wife of H. Franklin Parsons, M.D., of H.M.'s Local Government Board, of a daughter.
 RAHILLY.—On the 12th ult., at Secunderabad, Deccan, India, the wife of Surgeon-Major J. Roche Rahilly, M.D., 12th Royal Lancers, of a son.
 WEBB.—On the 7th inst., at Gibraltar, the wife of Brigade-Surgeon W. M. Webb, Army Medical Department, of a son.

MARRIAGES.

FRIKART—MCDONOGH.—On the 7th inst., at Zofingen, Canton Aargau, Switzerland, Emil Frikart, M.D., only son of the late Emil Frikart, J. P., of Zofingen, to Eliza Foster McDonogh, M.D., L.K.Q.C.P.L., daughter of John McDonogh, Surgeon, of Clapham, London. No cards.
 HOLMES—HAMILTON.—On the 6th inst., at Hamilton House, by the Rev. Joseph Corkey, M.A., LL.B., assisted by the Rev. George Magill, M.A., Dr. Henry Holmes, of Brookview, co. Tyrone, son of the late John Holmes, Esq., J.P., of Strandabrosny, co. Tyrone, to Charlotte Amy, youngest daughter of W. J. Hamilton, Esq., M.D., Fleet-Surgeon, R.N., of Hamilton House, Londonderry. (No cards. At home after Aug. 8th.)
 ROUGHTON—ROBINSON.—On the 1st inst., at the Parish Church, Streatham, by the Rev. T. T. Griffith, Rector of Seale, assisted by the Rev. W. C. Roughton, Vicar of Great Harrowden, Northamptonshire, and the Rev. J. R. Nicholl, Rector of Streatham, James Woolley Roughton, M.R.C.S.E., L.R.C.P., of Streatham-common, third son of James John Roughton, Esq., of Kettering, to Frances Mary, eldest daughter of Aug. O. Robinson, Esq., of Greta House, Streatham.
 STEVENS—BERGH.—On the 3rd ult., at Robertson, South Africa, by the Rev. A. MacGregor, Lewis William Stevens, L.R.C.P. & M.R.C.S.E., to Jesse Wilhelmina Bergh, youngest daughter of the late Olof M. Bergh, Esq., of Cape Town.

DEATHS.

FLUKER.—On the 19th ult., at Mussorie, from the effects of sunstroke, William Henry Fluker, of the Bank of Bengal, eldest surviving son of Robert Carr Fluker, M.D., J.P., of Berwick-upon-Tweed, in the 34th year of his age.
 GWYNN.—On the 11th inst., at New-street, Wem, Salop (very suddenly), Samuel Betton Gwynn, F.R.C.S.E., aged 67.
 SPENCER.—On the 2nd inst., at his residence, 9, Winckley-square, Preston, Lawrence Wilson Spencer, L.R.C.P., M.R.C.S.E., Medical Officer of Health to the Rural Sanitary Authority, youngest son of the late Lawrence C. Spencer, M.D., J.P., aged 29.
 WARD.—On the 16th inst., at 23, Finsbury-circus, Stephen Henry Ward, M.B., M.D., F.R.C.P., aged 61.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

PAUL BROCA.

A SPECIAL memoir of the life and work of Paul Broca—whose death on the night of Thursday, the 8th inst., we deeply regret to announce—is crowded out, with many other matters of interest, by the report of the proceedings of the Medical Council. The obituary will appear next week.

A. Z.—We cannot counsel any young man to enter the profession who has not private means at his disposal.

J. W. R.—See THE LANCET, March 27th, page 477.

SCURVY IN CIVIL PRACTICE.

To the Editor of THE LANCET.

SIR,—I read with interest the cases of Scurvy in Civil Practice by Dr. Eade, recorded in THE LANCET of June 26th. One example of that disease came under my observation many years ago, which may also have some interest.

On the 17th December, 1863, I was requested to see a farmer in good circumstances, aged about forty-five, who was said to be dying of cancer of the stomach. In addition to the stomach disease—which was in an advanced stage, and had occasioned a very restricted diet,—he was scorbutic to a degree which had made him bedridden and helpless. His legs were swollen, purple in colour, and so stiff as to be perfectly useless. Under change of diet, and lemon-juice in effervescence with bicarbonate of potash, the man recovered from the scurvy in a few weeks, and was able to leave his bed. He died of stomach disease on the 13th of April, 1864, nearly four months after I first saw him.

Although I had opportunities, more than thirty years ago, for watching the results of scurvy in seamen who were carried into hospital from vessels engaged in the whale fishery, I do not remember to have seen a better illustration of the disease than that which I have now briefly described.

Yours obediently,

Kington, Herefordshire, July 2nd, 1880.

G. S. GARRARD.

THE HOLLOWAY MURDER.

MR. SIDNEY SMITH, the Governor of Newgate, on Wednesday last received a communication from the Home Office, announcing Her Majesty's pleasure that the capital sentence passed upon James Sweetland for murder should be respited. The execution was to have taken place on Monday, the 26th inst. Probably the sentence will be commuted to penal servitude for life. The official notification was received at 5 P.M., and was at once made known to the prisoner, who received it with much emotion.

Nec temere nec timide.—Address the inquiry to the Dean of the Medical Faculty of the University of Durham.

SCURF IN RINGWORM.

To the Editor of THE LANCET.

SIR,—Can any of your numerous readers recommend a cure for scurf left after an inveterate case of ringworm of the scalp? Two healthy children (brothers) have been under treatment for eighteen months. The one had the patches covered thickly with scurf; the other has been almost free from it. Now the hair is quite long and healthy, and no fungi can be detected under the microscope. Several applications, as sulphur and white precipitate ointment, clear the scurf entirely away; but in the course of a few days after discontinuing them it reappears, not only on the spots formerly diseased, but for some distance around them. As nothing is said on this point in the interesting papers on Ringworm which have recently appeared in your journal, I should be greatly obliged to hear of a remedy.

Yours &c.,

July 6th, 1880.

M.D.

W. M.—Foreigners, desirous of practising medicine in Spain and her colonies, require to have a University Spanish diploma, and their own titles and qualifications must be previously verified before a Spanish Consul.

ROTHERHITHE.

SANITARY matters, as concern the medical officer of health's and inspector of nuisances' departments, appear to be working with some friction in Rotherhithe. At a recent meeting of the vestry, a question was raised as to the body of a child, dead from scarlet fever, having been suffered to remain several days in a room occupied by four persons, after the fact of the death had become known to the inspector of nuisances. The inspector imputed blame to the medical officer of health in the matter, but he appears simply to have made it evident that he was not working well together with that officer. The medical officer of health does not seem to have been called upon for an explanation.

Mr. W. Todd Patterson.—The information required will be best obtained from the Regulations, a copy of which may be procured from the College. Apply to the Secretary.

REGISTRATION OF DISEASES IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—I am glad to observe that in THE LANCET of July 3rd you draw attention to the subject of the Registration of Diseases in Hospitals, and I hope that the prominence you have given to the matter will lead to united measures being adopted for the development of this somewhat neglected branch of hospital work. Your correspondent, Mr. Howlett, justly remarks that a very vast amount of scientific material is lost and dissipated under the present mode of registration, and suggests that a uniform system of recording cases should be adopted at all hospitals. I am sure that all interested in the subject will fully agree both with the remark and the suggestion. But although I am convinced that a uniform system of registration is not only desirable, but an absolute necessity, I do not think that any such system could remedy either the whole or even a part of the present imperfections one must own exist in our hospital registers.

A definite system applied to the registration of diseases would render the clerical element in such registration certainly simple, possibly perfect, and undoubtedly give to the records a much more extended field of usefulness; but registration, I take it, deals not only with the arrangement of the material, but also with the character and quality of the material arranged. Imperfect facts, incomplete observations, and ill-recorded cases are more serious defects in registration than any flaws in the mere arrangement of the material. Indeed, the basis of all registration depends upon note-taking, and the more excellent the note-taking the more valuable the register, in spite of the fact that, from lack of some definite method of arrangement, the materials may not be so readily accessible as they ought to be. The simple arrangement and tabulation of acquired facts is under the sole control of one individual, the registrar, and for him to adopt a particular system in his arrangement would be no difficult proceeding; but the collecting of these facts is a matter less under control, less easy to influence, and yet no less in importance, and, while it forms the backbone of the register, can still be but little, if at all, affected by any system of registration, however excellent or precise. I would not for one moment underrate the great importance of a uniform system of record-keeping, as ably advocated in your columns; but if reform is to take place in the registration of diseases in hospitals, I fancy it is most required in the department of note-taking, and not the less because that department occupies a definite educational position. Difficulties in the matter of note-taking have probably presented themselves to most registrars, and I have no doubt that many have found that, however elaborate their system of recording those notes might be, such system does not insure with certainty excellence of quality in the matter recorded. As Mr. Howlett states, the notes of the cases are in most instances taken either by the registrar himself or by the students. The objections to note-taking by the registrar alone, are serious and well founded. In the first place, in most hospitals the extent of the work is such as to render it impossible for one man, or even for two, to carry it out in any way effectually, and, moreover, the registrar would very constantly lose the great advantage possessed by the dresser—namely, that of seeing the cases on their admission, and of participating in their immediate and subsequent treatment. Under any circumstances, details of a case obtained at second-hand may be regarded as less valuable than notes made actually on the spot. But, in the second place, the registrar, by undertaking such work, would deprive the student of a most valuable educational means; for although note-taking may involve a great deal of monotony, it at least involves the practice of accurate and repeated observations, the habit of arranging and criticising facts, and, not least, the faculty of expressing the matter observed in terms of precision. The encouragement and development of note-taking as an educational aid may, I believe, in many instances be considerably extended without disadvantage. On the other hand, if note-taking be entrusted solely to the dressers or clinical clerks, the value of the material noted is likely to suffer both in quality and amount, and it becomes at once obvious that such note-taking will be practically useless unless conducted under constant supervision, and here one is confronted with the great difficulty in the case. Allowed that the notes of cases should be taken by students, that such note-taking is of great educational advantage to them, and that without supervision its advantages is minimised, and the question naturally presents itself, By whom should such supervision be exercised? I think most certainly by the registrar. To expect the complete and systematic supervision that would be required from the proper conduct of the

work from the staff of a hospital is unreasonable. It would be almost impossible, even if considered advisable, for a surgeon or physician to go into the details of the notes of every case under his care every time he visited the wards. His general interest in note-taking, and his known determination to have it properly carried out, would be of the greatest influence with students, and, moreover, the habit of dictating special notes and the details of examinations of cases, as practised by many hospital surgeons and physicians, supply the register with its most valuable information. It is obvious that the more interest and the more active part the members of a staff take in note-recording, the more valuable will these notes become; but in the routine work of case-taking, in the minor details it involves, and in the supervision of any particular system of recording observations, they cannot be expected to take a constant part. How this supervision is to be conducted is a matter of difficulty, and it is upon this point that I think expressions of opinion are needed. Mr. Howlett considers it likely to prove a "superhuman labour." I would, therefore, wish to detail the method of exercising supervision I adopted during the time I held the post of surgical registrar at the London Hospital, and I think it will be seen that such a system is practicable, that it tends to promote the first interests of registration, and at the same time does not involve any superhuman labour. The ward notes at the London Hospital are taken upon loose sheets of paper fixed to a board by means of elastic, this arrangement allowing of their being readily bound at the end of the year. The dressers are supplied with a form for note-taking, compiled by my predecessor, and with diagram figures, if necessary, for marking the position of fractures &c. The notes are supposed to be taken according to the form supplied. The supervision required involved an examination of all the notes in the surgical wards two or three times a week; a mark affixed at each visit prevented the misfortune of reading the same notes twice. Where any defects were observed in the notes, the first difficulty was to communicate the fact to the dresser, who probably was not on the spot. This difficulty was easily overcome by the use of slips of conspicuous red paper, with a printed heading stating their source, and upon these slips any defects in the notes were written. These slips affixed to the bed-board were too conspicuous to be overlooked by the dresser, who on seeing the case would correct the defect in the manner advised. This plan I found answered very well, and would enable a registrar to compile notes upon any arranged plan. At the same time it is necessary that the staff and governing body should be interested in the matter of note-taking, or else the difficulty of enforcing rules of any kind becomes considerable. At the London Hospital this interest is vigorously expressed both by the staff and the house committee, and has been the chief means of greatly improving the whole aspect of registration at that place.

Finally, I hope that, now the subject has been broached, fresh interest will be aroused in the work of registrars, and that, if reform is to be made, attention will be directed in the first instance to the source of registration—note-taking.

I remain, Sir, yours faithfully,

FREDERICK TREVES, F.R.C.S.,

July, 1880.

Assistant-Surgeon to the London Hospital.

Surgeon-Major complains of an evil which must occur in all branches of the service—occasional slowness of promotion. It is quite impossible that all executive officers can obtain promotion to the administrative grades, or all deputy surgeons-general to the rank of surgeon-general. The late Government did a great deal to diminish the hardship of this by the creation of the grade of brigade surgeon, and by making the age of retirement for administrative officers 60 instead of 65. We do not see that any good would be gained by the publication of our correspondent's letter. In a few years we shall probably see promotion much more rapid. To make promotion flow at a steady pace in any branch of the public service is a problem which has not yet been solved, nor has our correspondent suggested any means by which this could be accomplished.

THE USE OF THE HOT VAGINAL DOUCHE.

To the Editor of THE LANCET.

SIR,—In reference to the use of the hot vaginal douche in your issue of July 3rd, I may mention that I have employed it with great advantage in two or three cases of rigid os, acting according to suggestions made by a correspondent in your journal some time ago. At the same time the mess made, in spite of every care, and the discomfort to the patient caused by the wetting of the bedclothes &c., constitutes a great obstacle to its satisfactory employment.

Perhaps some of your readers may be able to offer some advice on the subject. I am, Sir, yours &c.,

Meadowside, Putney, July 6th, 1880.

G. STANLEY MURRAY, M.D.

THE COST OF SCHOOL BOARD CERTIFICATES.

The following extract is taken from the *Catholic Times* of July 2nd:—

"Mr. John Flagg, M.P., has received a letter from the Educational Department, stating that whenever a medical certificate is required by School Boards, in explanation of the absence of a child from school, the cost of the certificate should be defrayed by the Boards themselves. Parents would do well to bear this fact in mind."

A. M. Y.—Our correspondent had better let his solicitor write to the Company, requiring removal.

SIR ANTHONY CARLISLE.

THE Council of the College of Surgeons has just acquired, by purchase at Christie and Manson's, the fine portrait painted by Sir Martin Archer Shee, President of the Royal Academy, of Sir Anthony Carlisle, who was elected President of the College in 1828, and again in 1837. It was engraved for Pettigrew's Medical Portrait Gallery.

"CRUELTY TO WOMEN."

To the Editor of THE LANCET.

SIR,—The efforts which you are making to render the work of the young women in drapery establishments less irksome and deleterious to them induce me to call your attention to the fact that ill health among this class is not wholly dependent upon hard work and bad treatment. Fashion has a great influence with these women, it may almost be considered a part of their business, and tight stays and wretchedly misshapen boots not only interfere materially with their powers of locomotion, but seriously impair their general health. The overwork and bad treatment to which you refer occur probably only in the second- and third-class shops; for in the leading establishments I have reason for believing that the principals take care of the women in their employ, and that the latter are perfectly satisfied with the treatment they receive. You are, doubtless, well acquainted with the various disorders produced by deformed boots and tight stays; but you possibly may have overlooked the important part they take in the ailments of the class under consideration.

There are other occupations for women which are probably quite as unhealthy in their nature as that of drapery houses, but few where so much attempt at fashionable dressing takes place.

I am, Sir, yours faithfully,

Queen Anne-street, July 6th, 1880.

Clinical Lectures ON DISEASES OF WOMEN.

By ROBERT BARNES, M.D.,
OBSTETRIC PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE III.

On the genital mucous tract; some general properties of mucous membranes, many diseases begin in them; it is an absorbing medium, a "toxicode" or "poison-route"; effect of closure of mucous canal; dysmenorrhœa by retention.

GENTLEMEN,—In pursuance of our scheme I propose to-day to begin the study of the pathology of the genital organs, by tracing the morbid conditions of the mucous membrane. There are many reasons for beginning thus. It is the most active in function. The processes of menstruation and reproduction are largely effected through its agency. Owing to this functional activity and other circumstances it is exposed primitively to a great variety of morbid influences. A very large proportion of the diseases of the genital organs begin in this tissue, and it rarely escapes being involved in the diseases which take their origin in the other tissues. It is peculiarly exposed to direct injury, traumatic and toxic, from without. Like the mucous membranes of the respiratory and alimentary systems, it is remarkably prone to suffer congestion and inflammation from the influence of cold. Although it may be true that in zymotic diseases every tissue in the body suffers from the empoisoned blood, still it is not less true that the effects of the poison are often especially conspicuous in the mucous membranes. And this applies to the genital mucous tract along with the rest. Many years ago I made the observation that variola and scarlatina were attended by intense vaginitis which might be the unsuspected starting-point of chronic disease. Again, we know that syphilis primary, secondary, and tertiary, first in the case of primary syphilis, and if not always first in the constitutional phases, most conspicuously writes its history upon the mucous membrane. Again, we know that it is the mucous membrane which most readily shows the work of constitutional diatheses, as struma, tuberculosis, and cancer.

The study of the action of remedies—we have it from Hippocrates, and daily experience proves the wisdom of the aphorism—shows the nature of the disease. Now, excepting on the skin, we can nowhere see the action of remedies so well displayed as on that part of the genital mucous tract which is brought into view by the speculum. This is true of some constitutional remedies, as of mercury and iodine, in syphilitic affections. But it is of far wider and more instructive application in the case of topical remedies. The immediate and consecutive effects of the actual cautery, of caustics, astringents, styptics, antiseptics, solvents, anodynes, offer a wide and most interesting field of clinical experiment,—a perfectly legitimate field, because the motive of their employment is the good of the subject. In this field of clinical study we have the opportunity of not only observing the topical action of various agents upon healthy and diseased mucous membrane, but of contrasting this action with that of morbid agents, and thus of extending our knowledge of pathology. We shall, of course, best follow up this study by actual demonstration. I therefore leave it for the present, merely stopping to remind you of the fact that several agents, more or less chemically and therapeutically potent *in loco*, may be absorbed through the mucous membrane into the system, and produce general toxic effects. Accidents of this kind not infrequently occur. They enforce the important physiological law that the mucous membrane is an active absorbing medium. They enforce the correlative clinical law of caution in the topical employment of toxic agents. They suggest—and to this point I wish particularly to invite your attention, because it is not sufficiently appreciated—that we may in many cases turn this property to account, and so apply remedies to the mucous membrane as to produce valuable constitutional effects.

No. 2969.

The mucous membrane is thus an active "poison-route." To give two or three examples. There is first the familiar one of narcotic and sedative pessaries and suppositories. Morphia we know, thus used, acts first locally as a sedative, secondly as a narcotic. Mercury in the form of pessaries, or as calomel applied in substance to syphilitic warts, or as the caustic-acid nitrate to hyperplastic tissue, not only acts with immediate local effect upon the morbid tissues, but it may be absorbed, and thus, carried throughout the system, it exerts its specific constitutional influence; and coming round again through the circulation to the morbid structures where it entered, it again affects them by exerting its modifying influence upon tissue-nutrition. This combined topical and constitutional medication is especially well seen in the action of iodine. In some cases of disease of the uterine mucous membrane, of hyperplasia of the muscular coat, and of peri-uterine inflammatory deposits, the free application of iodine in the liquid form surpasses every other mode of treatment. Iodine permeates the tissues of the uterus either by direct imbibition or osmosis, or through the veins and lymphatics, acting first directly upon them, and thus gets into the general circulation. Thus I have seen intense iodism, manifested by salivation, by the breath, and by the starch test on the skin and on the urine, follow the injection of a solution of iodine into the uterus. But injections require great care. You may introduce iodine and mercury in the form of ointment or by painting. I believe that in this way I have obtained excellent results. At any rate, it is useful to bear in mind that we may, in cases where it is inconvenient to administer mercury and iodine by the stomach, realise what we want by applying them to the genital mucous membrane.

One more example. Of late years a method practised by Harvey of washing out the uterine cavity when charged with noxious matter has come into vogue. The favourite agent at present in use is a solution of carbolic acid, and thus we get the twofold good of clearing the uterus of foul matter and of modifying the surface which produced it. But we may, I am persuaded, obtain a third good. We may, by throwing carbolic acid, or, better still, iodine or quinine, or sulphate of soda, into the uterus, chase the septic matters through the tissues and vessels by which it entered. We may thus, whilst cutting off further supply of poison to the system, do much to neutralise the action of that which had already entered. In this way, you see, the antidote tracks the poison.

There is this great and singular advantage in beginning pathological investigation with the study of the mucous membrane, that it is so completely under observation. It lends itself so readily to direct inspection and touch that we may here acquire the most accurate and complete knowledge of morbid processes, knowledge which we may usefully apply to aid ourselves in the investigation of the pathology of the deeper and less accessible tissues. We thus, you see, proceed by the most logical order from the comparatively easy to the more difficult. And since there is unity in pathology, our progress will thus be considerably simplified.

Let us now recall a few general facts belonging to mucous membrane in order to trace their bearing upon our special inquiry.

All mucous tracts have external openings. These external openings serve for ingestion and egestion. All mucous membranes secrete fluids in varying quantities, according to varying physiological and pathological conditions. In certain of these conditions, often recurring, these secretions must be excreted—that is, discharged from the body. Hence, a first necessity for health and safety is free patency of the mouths or orifices which open on the surface. The patency of these mouths or orifices is regulated by sphincters. The secreting action of mucous membranes is governed or modified by several factors. First, we may note the influence of the nervous centres. The influence of emotion in suppressing some secretions and in increasing others is familiar. There seems to be an inhibitory power exerted by the brain over certain glandular systems, especially marked in the waking state. The mucous canals are embraced by a coat of involuntary muscle, and their outlets are guarded by voluntary circular muscles, partly under the dominion of the will, partly under reflex influence. A mucous canal generally resents the presence of any excess of matter in it. Reflex irritation is set up, and the muscular coat becomes the active factor in discharging the offending matter. In health this is accomplished almost insensibly; in disease pain and colic attend, and the sphincters often share in the distress. The

glandular system of the mucous membranes acts in alternation or in compensation with the skin. All possess an absorbing property. All act occasionally as depuratories, like the skin. All may act exceptionally in compensation for, or vicariously with, each other. Thus again you see how physiology and pathology link all parts of the body together in one indissoluble whole; that is, how they re-integrate what the anatomist and the specialist dissect and differentiate. The genital mucous tract is subject to all these common laws.

Another fact we may recall is that each part of a mucous tract fulfils a particular function or part of a function; and the particular duty involves particular variations of structure, mainly seen in the glandular element. And these particular functions or parts of functions are attended by particular secretions. I will but suggest to you the example of the alimentary tract. From the mouth downwards, through the pharynx, stomach, duodenum, ileum, colon, rectum to anus, we have a succession of special glands adapted to the successive stages of duty. So in the genital tract, from the Fallopian tubes, through the uterus, its body and neck, vagina to vulva, we have a succession of glands adapted to different stages or kinds of duty. One general duty is common to all mucous membranes—that is, the secretion of a moderate amount of mucus for the purpose of lubrication, to obviate the tendency to atresia, to keep the canal open, to facilitate the passage of bodies which have to make their way along the canal. Except for sexual acts and parturition, the amount of fluid thus secreted normally is rarely in such quantity as to give rise to external discharge. The origin of these secretions is principally in the cervical canal of the uterus, and at the vulva, from the vulvo-vaginal gland—that is, at the sphincters, the gates of the canal.

We need not now refer more particularly to this function. I wish especially to dwell upon the special share the uterine mucous membrane takes in the function of menstruation. Menstruation is coeval with the potentiality of reproduction; it is the overt or visible effect of ovulation. Assuming, for the sake of obtaining a definite idea of the relation of ovulation to menstruation, that menstruation proper, meaning by this word the periodical flow of blood from the uterus, returns every twenty-eight days and lasts four or five days, closer observation will reveal the fact that there is a preparatory work going on at least eight days before the flow begins. This work is announced by nervous phenomena of varying intensity according to: (1) idiosyncrasy of the subject; (2) to the state of the ovary and uterus. The main characteristic is exalted nerve-tension; the emotional element is often predominant, the temper is more sensitive, the reflex or diastaltic function is more active, less readily curbed by the will. Concurrently with this nerve-tension we find the heart and vascular system in greater activity; the sphygmograph shows high arterial tension resembling the high tension of pregnancy. Indeed, the two conditions exhibit many other points of resemblance. Now, these conditions are intimately linked with the maturation of the ovum going on in the ovary. The *primum mobile* of menstruation is probably in the ovary, the uterus playing a secondary part. This secondary part is marked by four phenomena: (1) The development of the mucous membrane of the cavity of the uterus into decidua; it becomes thickened and its glands enlarge. (2) There is an active determination of blood to the uterus as well as to the tubes and ovaries. These two processes set in probably very soon after the commencement of the nervous tension provoked by the maturation of the ovum. (3) There is the escape of blood from the lining membrane of the tubes and body of the uterus, and concurrently with this, (4) the breaking-down and exfoliation of the decidua. One or two more points call for attention. The determination of blood in unusual proportion to the genital or pelvic vascular region involves an increase of the activity of the circulation throughout the body. Hence we may see, if we search intelligently, a general hyperæmia of the skin and mucous membranes. The vessels everywhere seem more distended. If there are piles, they now become turgid and are apt to bleed. And when tension is at the maximum, the distension is relieved by the bursting of blood from the uterus. Almost immediately the sphygmograph will show a fall of tension. Given, normal conditions of system and of structure of the uterus, speedy, almost instant relief ensues. Although the blood-flow may go on for some days, the mimic pregnancy is at an end, and things subside into the ordinary quiescence. You will see in this central

arterial tension and general peripheral hyperæmia, a key to the phenomenon of "vicarious menstruation," or "menoxenia." These cases are deeply interesting. I hope to make them the subject of a special lecture. Should there exist any obstacle to the flow of blood from the uterine surface, or should the physiological blood-tension be less instead of higher at the uterus than elsewhere, the full vascular system will seek relief at some other outlet. This may be the nares, lungs, stomach, small or large intestine, bladder, or, in rarer cases, the skin, or the nipples, or the conjunctiva. Almost always, you see, a mucous membrane, proving Trousseau's aphorism, that all physiological hæmorrhages come from mucous membranes. The reason is obvious. The blood so poured out finds a ready vent. If it does not thus find exit by a mucous membrane there is imminent danger of extravasation into a serous cavity or into the parenchyma of vital organs. Some cases of apoplexy of the brain and lungs are thus accounted for, especially in subjects approaching the climacteric. Can we shut our eyes to the logical therapeutical deduction? If we see the system labouring under high nervous and vascular tension, the uterus failing in its duty, shall we risk effusions in abnormal places, or shall we not rather bring relief by tapping the gorged vessels at a place of our own selection? The principle and practice are old, and therefore have fallen under the ban of modern progress. In young persons the best plan is at the time of menstrual molimen to apply five or six leeches to the anus, thus tapping the pelvic vascular region. You attract the blood-flow to the natural site and aid in restoring the lost physiological habit.

In climacteric women, some of whom make blood with surprising facility, and in whom there is usually more head-disturbance, greater relief is often attained by cupping from the nucha, and sometimes bleeding from the arm is better still. I would advise you not to look upon venesection as an obsolete or exploded practice. Extremes are proverbially bad. Because venesection had long been abused, that is no reason why the readiest and most potent agent known for reducing dangerous vascular tension should be absolutely abandoned. You see in this example of menstruation that hæmorrhage is a physiological process; and since pathology is but physiology out of order, hæmorrhage, spontaneous or artificial, may be useful in pathology.

Two other effective means we possess of relieving tension by diminishing the volume of the blood. First, purgation; second, reducing the supply of food, especially of fluids, and, above all, of stimulants.

The menstrual blood comes mainly by exudation from the mucous membrane of the body of the uterus. But the menstrual fluid does not consist of blood alone. It is freely mixed with, diluted, and kept fluid by mucus. In many women the first appearance or show consists entirely of mucus; then comes a little ruddy blood; then a fluid, glutinous, darker-coloured, consisting of blood and mucus in variable proportions; and lastly mucus again, simple or blood-stained. And with this you will find, by the naked eye or microscope, débris of the shed mucous membrane. The mucus comes from the glands of the body of the uterus and from those of the cervical canal. This mucus is alkaline. Of this you may get proof by turmeric paper carried on forceps into the neck, or by a solution of iodine in small quantity, the colour of which will be discharged. This mucus it is which maintains the fluidity of the blood, thus facilitating its escape as fast as it flows from the uterine surface. This is one of the postulates for easy menstruation. The blood must escape readily, and for this end two conditions are required: one is that the blood be moderate in quantity and fluid; the other is that the canal for excretion be freely patulous. If the reverse conditions obtain—that is, if the quantity of blood poured out be in excess of that of the mucus—a portion coagulates, and is for a time retained in the cavity of the uterus. This is enough in many cases to set up dysmenorrhœa, or painful menstruation, as we observe it in many multiparæ. For the retained clots, under the general law already cited, irritate, set up reflex expulsive efforts, and these are marked by colic. But there is another efficient cause of dysmenorrhœa frequently attended by, and, indeed, inducing that just described. This is obstruction of a mechanical kind in some part of the excretory cervical canal. This is sometimes called the obstructive or mechanical theory of dysmenorrhœa. There are two principal or primary efficient causes of obstruction. First is atresia, or constriction, more or less marked at some part of the cervical canal. This is most frequent at the os externum, which is

often so small that the point of a sound is passed not without difficulty. When this is the case the canal above is commonly more dilated than natural, as we are accustomed to find in other mucous canals when obstruction exists at the outlet. The second efficient, sometimes occurring alone, but often combined with the first, is flexion, amounting at times to angulation, in the cervix, or at the junction of cervix and body. When this flexion exists, the cervix, like a bent tube, is closed by the spur or convexity of one wall being compressed into the concavity of the opposite wall. When one or the other or both of these conditions occur, it generally, not always, happens that dysmenorrhœa ensues. Blood is imprisoned in the cavity of the uterus, coagulates and sets up colic pain. The normal course of menstruation is disordered. Nor is the situation without danger. In a former lecture I described the mechanism by which fluids are propelled from the uterine cavity through the tubes into the peritoneal cavity. Here we have the conditions for this catastrophe. There is accumulation of fluid in the uterine cavity, part of it, perhaps, clotting; it excites reflex or diastaltic action, the body of the uterus contracts concentrically in the endeavour to throw out the offending matter, the lower or natural outlet is partially closed; the tendency is great to force the fluid along the tubes. And this tendency increases with time, for egress being difficult by the lower orifice the compressed fluid dilates the cavity above it, first the body of the uterus, then the tubes. Thus we get one of the forms of retro-uterine hæmatocele. I do not say that this accident is frequent, but I know that it occurs occasionally in an aggravated form, and I have seen not a few cases of pelvic peritonitis in young women the subjects of habitual dysmenorrhœa, of which this back flow or regurgitation of a small quantity of menstrual blood offers the most rational explanation.

I could heap proof upon proof in support of this theory of *dysmenorrhœa by retention*, as I prefer to call it. I will but mention two or three before I pass to the crucial test of treatment. There is one form of dysmenorrhœa by retention, not frequent certainly, but so complete in its history that its pathology is universally admitted. I refer to what is known as menstrual retention from total atresia at some point below the proper uterine cavity; for example, in the vagina or from imperforate hymen. Here we witness the whole series of events I have above described in unmistakable evidence. The vagina first dilates above the imperforate hymen. (Here is a valuable specimen from our museum showing this, of which a drawing is given in my book.) Then, in succession, the cavity of the cervix, that of the body, and of the tubes. The accumulating fluid sets up pains like labour-pains; the concentric contraction of the uterus drives the blood in all eccentric directions, and unless the hymen gives way or is punctured, the danger is imminent of the tubes, the weakest part, bursting; or fluid may be projected through the tubes without their bursting. Now all this is precisely what occurs in a modified form and degree when the obstruction is only partial. The points of resemblance may be carried farther. We see one in the characters of the retained fluid. In the exaggerated case of imperforate hymen the menstrual blood is commonly of sticky, treacly consistency, dark in colour, showing blood-corpuscles breaking down in fatty metamorphosis; sometimes it contains loose, soft clots, easily breaking down. The fluid in severe cases of dysmenorrhœa from retention often closely resembles this. Why? Is it not because it is affected in a like manner?

But, admitting that the extreme catastrophe does not occur—and I readily admit that it is rare,—still let us ask, Are there no other dangers to be apprehended? Most assuredly there are. Menstruation cannot be performed month after month under the difficulties described with impunity. One inevitable result of constantly-recurring congestion and spasm is alteration of the muscular wall of the uterus. It becomes first thickened from excessive action, then hypertrophied from hyperplasia, which may pass into fibrous change. The mucous membrane undergoes chronic change; that of the body is impeded in its normal development into decidua and exfoliation; instead of being shed in impalpable débris, it is apt to be cast off with pain in shreds, perhaps entire as a cast of the uterine cavity, thus constituting one form of what is called “dysmenorrhœa membranacea,” or sometimes “inflammatory dysmenorrhœa.” In the cervix especially the glands become hypertrophied, and instead of yielding their due supply of clear viscid mucus, secrete a copious, often turbid, muco-purulent fluid; one form, a common one, of leucorrhœa. Here then we

have gradually developed disease of the uterus, entailing serious and often very distressing constitutional disorder. The discharges drain the blood and impair nutrition; the bulky uterus becomes more or less displaced, causing local distress; and the nervous system is worn by the constant pain.

Now this theory, built as you see upon a solid foundation of facts and well-known physiological and pathological laws, is not universally accepted. The facts of the coincidence of stenosis of the os externum or os internum of the uterus, or of flexion with dysmenorrhœa, are beyond dispute; but the reasoning, the pathological deductions from them, are disputed; and consequently the logical therapeutical deduction is practically repudiated.

This seeming contradiction, or perverseness I am almost tempted to call it, may be explained by a metaphysical reflection. It is an infirmity of the human mind—from which none of us are altogether exempt—to cling to one favourite idea, to the exclusion of others, which may each be the idol of some other man. Let me mention two or three rival theories:—Firstly, congestion explains dysmenorrhœa; secondly, inflammation explains it; thirdly, the membranous decidua; fourthly, some general nervous or other constitutional disorder may explain it. And certainly there is truth in every one of these and other theories which I cannot stop to enumerate. The causes of dysmenorrhœa are various. But if you watch a few cases of dysmenorrhœa in women who have never been pregnant, through all the phases of their history, you will hardly fail to recognise the conditions I have described.

And now if we apply the recognised rules of treatment when we meet with closure, complete or partial, of mucous canals, what is the indication here? Can we hesitate for an answer? If the anus is closed—imperforate, as in some new-born infants, or obstructed by disease as in adults—do we not make an opening at the anus, or failing that open the bowel higher up, as in colotomy? In the case of stricture of the urethra, do we not dilate if we can, or failing that, cut into the canal above the seat of stricture? Why, then, should the genital canal be treated on different principles? The surgical treatment, however, of these cases demands especial care, and will be discussed on another occasion.

Clinical Lectures ON

SOME CASES OF HEART DISEASE.

*Delivered at the Hospital for Consumption and
Diseases of the Chest, Brompton,*

By R. DOUGLAS POWELL, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL, SENIOR ASSISTANT-PHYSICIAN TO THE
MIDDLESEX HOSPITAL.

LECTURE III.

GENTLEMEN,—The second form of mitral disease—the diaphragm or true buttonhole variety—being, as I believe, always of inflammatory origin, varies much more in degree of narrowing, and is not unfrequently complicated with other valve lesions. In fact, after we have taken out from the general group of cases of mitral stenosis those well-marked examples which constitute the funnel variety, the remaining cases are not nearly so uniform and well defined in their characters. I have, significantly, this form of cardiac disease more richly illustrated by morbid anatomy than by clinical examples. In these large hearts you will observe enlargement of the left auricle, right ventricle, and left ventricle; and you will note the thickened, more or less tuberculated and rigid valve stretched across the mitral orifice, presenting a mere transverse chink, a well-marked buttonhole, or a wider opening. In this heart—the largest and heaviest specimen I have seen, weighing, with portions of adherent pericardium, thirty-one ounces,—you will observe that the valve, although very decidedly narrowed, admits of unusually free regurgitation.

The following is a list of phenomena presented by cases of

the diaphragm, or true buttonhole variety of mitral stenosis, in which the curtain of the mitral valve is stretched more or less tightly across the orifice to form a diaphragm-like partition between auricle and ventricle:—

MORBID ANATOMY OF HEART.

Valve.—Stretched across the orifice, with only slight convexity towards the ventricle; a transverse, buttonhole-like slit, extending across the centres of the “diaphragm,” thus formed; valve greatly thickened, especially around margin of buttonhole, which is often nearly occluded by semicalcareous projections or vegetations; size of aperture very variable; papillary muscles enlarged, and cords thick and matted; regurgitation through valve free, according to size of aperture.

Left ventricle always hypertrophied and dilated, often very greatly so.

Left auricle greatly thickened and enlarged, and more dilated than in funnel variety.

Right ventricle hypertrophied, dilated, and hardened; never exceeds the left ventricle so far as to extend beyond it to form the apex of the heart.

Other phenomena.—Lungs heavy, congested, and toughened, sometimes with minute hæmorrhages or typical “brown induration”; pulmonary apoplexy; infarcts in other organs; enlargement and hardening of abdominal organs from congestion.

CLINICAL PHENOMENA.

Cardiac impulse.—Apex-beat outside nipple-line, and lower than natural; impulse diffused between apex and sternum, and strong, but usually irregular.

Thrill short and irregular, sometimes before, sometimes with systole; rarely absent.

Pulse, as a rule, irregular, small, and frequently intermittent; varies much from time to time.

Bruit.—1. Double; the presystolic continuous with the systolic, so as to make up a continuous but undulating murmur, through which, but at variable periods of it, the first sound of the heart can be more or less distinctly heard. 2. The murmur varies often from day to day, now being more decidedly systolic, again more presystolic. 3. Only the systolic murmur may be audible, and with the stronger beats of the heart only. Sometimes the murmur will completely disappear for a while, the heart's action being extremely irregular.

First sound usually more or less distinctly audible through the bruit; sometimes very loud and battering; sometimes wholly lost in systolic murmur.

Second sound accentuated, but less clearly so than in the funnel variety; more “thudding” in character; often reduplicated.

Patient becomes distressed at an early period of the disease from palpitation and heart cough. Dropsical and other astylosic symptoms supervene.

Onset of symptoms dates from a first or second attack of rheumatism.

Origin of Disease.—In almost all cases from rheumatic endocarditis. A second attack of rheumatism probably more likely to induce this form of lesion than any other. Syphilis may probably be an occasional cause of the disease.

Prognosis.—Very unfavourable, and directly so in proportion to preponderance of regurgitation. Tendency to sudden death from paralysis of right ventricle from over-distension.

FIG. 2.

FIG. 3.

The vertical lines rising from the base line (Fig. 3) represent the first and second sounds of the heart. The shading lines mark the position of the murmurs, and the dots signify thrill. The diagram, Fig. 2, illustrating the position of murmur and thrill in the funnel form of the disease, is placed above for comparison.

The above list epitomises the main features by which the diaphragm variety of mitral narrowing is marked. The

symptoms may be said to be those which characterise the funnel variety in the advanced stage, when mitral incompetency supervenes. In typical cases the transverse cardiac dullness is greatly increased, and with the impulse diffused between apex and sternum, shows both ventricles to be enlarged. The apex-murmur is double, its double character being only recognised, however, on attentive auscultation, for the presystolic runs into the systolic murmur, only a slight variation in pitch distinguishing them. The first sound of the heart can often be heard through the double murmur, partially obscured by them. There is in these cases thus a murmur on both sides of the first sound (Fig. 3), by which feature they are very strikingly separated from those of the funnel variety. In other cases, and they are the most serious, the first sound is altogether replaced by murmur. A satisfactory account of the murmur present in this variety of mitral disease is a matter often of great difficulty to the most practised auscultator, this very difficulty being an important factor in the diagnosis. It is difficult from physical signs alone to distinguish the last stage of funnel mitral from the diaphragm variety, nor can I say that the distinction at this stage continues to be of any practical importance; for from this point the two diseases start about level as regards prognosis, the mechanical conditions present in both being about the same. The following case, awaiting your examination, illustrates this point.

Edith T—, aged fifteen, had rheumatic fever when four years old. Has suffered occasionally from palpitation when digestion disordered, otherwise no complaint of breathlessness or inconvenience until one day in December, 1868, when she caught a cold, which was followed by pain in left side, cough, and blood-stained sputa, which laid her up for six weeks. She had a relapse soon afterwards, and has been breathless and suffered from cough since; never had dropsy. Apex-beat at sixth space, one inch and three-quarters outside, and two inches below nipple. Area of dullness bounded by third cartilage, right parasternal line, and apex-beat. A short presystolic thrill and murmur over a restricted area at apex, running into the first cardiac sound, with long, high-pitched systolic bruit audible all over heart, well-conducted to sternum, and round to scapula. Second sound at pulmonary cartilage accentuated, thudding, perceptible to finger applied. Pulse quick, regular. Veins of neck full, and fill from below (patient lying down). No dropsy or manifest enlargement of organs. Urine deposits lithates, and contains a slight trace of albumen.

I take this case to be one probably, in the first instance, of mitral regurgitant disease, in which narrowing has subsequently taken place by irritative growth, thickening and shortening the valve and contracting its orifice, and, perhaps, that of the mitral opening also.

This case further illustrates two points, upon which I touched in my last lecture—viz.: first, that hypertrophy in early life is a better and more durable hypertrophy. It has carried on this patient's circulation through eleven years of great mechanical difficulty; and, secondly, although now we have distinct evidence in the filling of the veins of the neck and their pulsation that the heart is yielding, yet we have no present dropsy. The heart is still acting regularly; the *vis à tergo* of the left ventricle is still powerful enough to sweep on the blood through the capillaries, and thus to prevent that retardation in the tissues and organs which favours effusion and engorgement. The condition is very analogous to that of another patient who came in with some dropsy, but who under the influence of rest and digitalis has acquired increased ventricle power and lost the symptoms. The tension of circulation is now, however, great, and, unless we can relieve it, we must soon get astylosis and dropsical phenomena, the heart's action and pulse becoming irregular.

The difficulty in diagnosis consists chiefly in recognising this form of stenosis from—1. Irregularly acting heart from chronic dyspepsia, &c. 2. From mitral regurgitation, simple. 3. From aortic regurgitation. One would think that no one disease could be confounded with three such distinct diseases as these. But variability as regards murmur and rhythm is the crowning feature of this valvular lesion—variability from case to case, and in the same case from time to time.

In some cases and at some times no murmur at all can be heard; the heart's action is tumultuous and irregular, and save for perhaps a slight thrill, easily overlooked, or for a brief whiff occasionally audible (whether systolic or pre-

systolic one cannot always tell) the diagnosis from functional irregularity is extremely difficult, for dyspeptic symptoms are never wanting. The history of the case and a second careful examination after long repose, when we may more accurately estimate the evidences of ventricular enlargement and hypertrophy, and the value of that important sign of mitral disease, accentuated *pulmonary*¹ second sound, will usually clear up the case. The rhythm of the murmur, if there be one, may also during repose be better judged of. The presystolic portion of the bruit often for a time disappears, and the mitral systolic becomes alone audible, leading to a diagnosis of the simpler disease. A walk up and down the room, however, only renders clearer the mitral systolic bruit if regurgitation alone be present; and in the other case it often brings out the presystolic portion of the murmur. A thrill, however short, is also almost diagnostic of contraction.

I bring a case before you to-day (H. H.—, a dyer, aged twenty-nine), in which for a long time I had great difficulty in deciding whether the murmur was *diastolic aortic*, or double mitral. When the man came in he was extremely breathless and weak, scarcely able to walk across the room. No first sound was audible, and the heavy thudding second sound, succeeded by a long bruit, very loud and audible all over the heart, closely resembled aortic regurgitation. The pulse, it is true, although sharp, was not characteristically aortic, and the man had some pulmonary congestion and enlargement of liver and spleen. Still the rheumatic history was not distinct; he was laid up with pains in the hip-joints for three weeks five years ago, and had had syphilis eight years previously: he had been accustomed to drink, and four years ago had been knocked down by the falling of a heavy wet carpet upon him—a blow which did not apparently injure him at the time, although next day he spat a little blood. The onset of his cardiac symptoms had been gradual but progressive for three months, supervening upon a lowered state of health apparently induced by gastric catarrh of alcoholic origin. Here then we had syphilis, drink, and possible strain, all favourable to aortic rather than to mitral disease, in a case the physical signs of which were very uncertain. The man is now, however, improved, having acquired distinct ventricular hypertrophy, and the physical signs are accordingly more distinct, although they are yet not entirely satisfactory. With the signs of hypertrophy of both sides of the heart there is a distinct second sound at the base, and a short systolic thrill at the apex, with a prolonged wavy systolic—in part presystolic—murmur, through which the first sound can be heard. The murmur is most loud at the apex, and is audible in the scapular region. There is a slight diastolic whiff at the base of the ensiform cartilage. I take it that the mitral regurgitation here is free, and is attended with some narrowing. The valve may have been injured, but more likely syphilis has to do with the origin of the disease, and to syphilis the enlargement of the liver and spleen may be in part due.²

Taking the physical signs of a number of cases of mitral stenosis with regurgitation, of which the diaphragm mitral valve is the type, we find that a *variable character of the murmur or murmurs is an important diagnostic feature*. If there is any dispute over a case of cardiac disease of rheumatic origin, that is an important fact in favour of stenosis.

As regards prognosis, these cases are far more serious than those of funnel mitral disease. They begin, so to speak, on a level with that stage of the latter disease in which over-strain of heart or of valve has occurred. Again, these cases are serious in direct proportion—excluding, perhaps, the most extreme degrees of stenosis—to the freedom of regurgitation. There is with stenosis necessarily a constant difficulty in the pulmonary circulation, a constant over-fulness on the pulmonary side of the valve, but the right ventricle and left auricle between them, the one supplementing the other, can contend against great difficulties, as we have seen in speaking of the simpler form of constriction. So long as the valve, constricted though it be, interposes a thick diaphragm which but slightly leaks and takes off the backward pressure of the left ventricle, the patients are better off than those with simple but free mitral regurgita-

tion. But if with constant obstruction we have anything like free regurgitation, the ventricular systoles oppose one another, and we have the most aggravated form of mitral lesion possible, speedily productive of other signs of heart failure and of a specimen after this pattern—the big heart already referred to.

THE WINTER STATIONS OF SICILY.

By C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES
OF THE CHEST, BROMPTON.

THE growing number of our winter emigrants, and the increased facilities of travelling, tend to widen the area of our health resorts, and the building of good hotels and pensions open to invalids excellent climatic stations hitherto closed to them by this one defect. As it is desirable to have as large a choice as possible I propose to say a few words about Sicily in the light of a sanitarium, and having made a tour in that island during the late severe winter, I can speak from recent and, I hope, trustworthy information. Very few English invalids, or even tourists, reach Sicily, the most part stopping short at Naples. This is partly owing to a dislike of the sea voyage to Palermo or Messina, or the terribly fatiguing land journey *viâ* Foggia, Bari, and Reggio, but it is still more to be attributed to the stories of brigands so rife in the English papers, which are, for the most part, gross exaggerations. Since the capture of Leone's band the danger has greatly diminished, and even the most timid strangers can now walk and drive in every part of the country without fear; moreover, it should be borne in mind that the disputes which have led to brigandage relate to landlords and landholders, and do not affect travellers and visitors, about whom the brigands know and care little.

The sub-prefect of Termini, near Palermo; assured me that he and his brother rode alone last autumn on a ten days' tour to visit their possessions near Girgenti in perfect safety, although this was formerly accounted one of the most dangerous districts, and other authorities confirmed this improved report of the country.

The east coast of the island is well worth our notice on account of its exposure to the south-east and its shelter from northerly and north-westerly winds by the Montes Neptunii or Pelorides, and by the huge mass of Etna, while the presence of the Mediterranean tends to equalise the extremes of temperature experienced by the inland localities. This region is one of the most beautiful in the south of Europe, commanding views of the Straits of Messina, of the mountains of Calabria, and of the wooded hills of Aspromonte; while on its own shores lie the exquisite headlands and capes of Capo Alessio and Taormina, and the picturesque and smiling villages which fringe the lower slopes of Etna, and are sprinkled over the mountain sides.

Owing to the latitude, to the shelter from cold winds, and, in the case of the Etnean district, to the volcanic soil, this region is of remarkable fertility, and produces wine and oil of very excellent quality. Oranges, lemons, and almonds are abundant and delicious, their trees attaining a size nearly double that of their brethren on the Genoese Riviera, and the wild flowers appearing much earlier and in greater profusion.

When we reach Syracuse the vegetation is still more southern, especially in the well-sheltered Latomia or quarries, in one of which we saw a good-sized *Pointzettia* tree, and the African papyrus fringes the river Anapo, the only stream where it grows wild in Europe. But it is the luxuriance of the *Cactus opuntia* which strikes the visitor most. Its presence everywhere, on the hill side, in the valley, on the fertile plain, and on the towering crag, sometimes grown in fields, and sometimes marshalled into hedgerows, forms the chief feature of the vegetation of Sicily. The old plants lose in time their flabby appearance, and present knotted and gnarled stems, consisting of wood worthy of an exogen. The finely-coloured figs, growing on the fleshy leaves, while much appreciated by the upper classes for their juicy and cooling qualities, form a staple food of the poorer

¹ The cases of intermittent irregularly acting heart referred to may be of gouty origin and attended with notable accentuation of the aortic second sound.

² This patient died in the hospital, but unfortunately no post-mortem could be obtained. The slight diastolic whiff at the ensiform cartilage was probably due to some aortic leaking.

Sicilians. On this coast three towns might be utilised for English invalids—Catania, Aci Reale, and Taormina,—the two former being already in great reputation among the Viennese physicians, who send a good many pulmonary cases to Sicily.

Catania is situated on the Mediterranean on the slope of Etna, being built, and partly hewn out, of the lava rock. It is about four hours by rail from Messina, and between sixteen and eighteen hours by rail and diligence from Palermo. It faces south-east, is tolerably sheltered from the north and north-west by the mighty Etna, the glory, and, alas, the terror, of the eastern coast, whose bold outline closes in the chief street of Catania, the Strada Stesicorea or Etnea. The town is comparatively unsheltered on the north-east side, and complaints are made of occasional cold winds from that quarter. The meteorology has been most carefully studied at the University observatory, and Dr. Ughetti's excellent brochure¹ contains reliable information on all points, the tables being generally based on twelve years' observations. From these it appears that the winter (Dec., Jan., and Feb.) mean temperature is 52° F., about three degrees higher than that of Mentone, but slightly lower than that of Malaga, and the extremes lie within a moderate range. There is rarely ever frost, but during the recent severe season snow fell one day, and, though it did not lie on the ground, created great astonishment amongst the natives, who had most of them only viewed it at a distance clothing the sides of Etna. The rainfall is 528 cubic millimetres, distributed over forty rainy days in the year, occurring in the winter and autumn months. The mean annual percentage of humidity is 70, a figure considerably greater than that of Nice or Mentone. The prevalent winds in winter on the south-east and south-west—the former the well-known sirocco, terrible in summer—are not unpleasant during the winter months. These data show a mild winter climate, dry compared with that of England, but not so dry or subject to such great extremes as that of the Riviera, and gaining the advantage over the latter which 5° southern latitude give. Catania is a bright, clear, bustling town of 84,000 inhabitants, built on a wave of an old lava stream, and consequently abounding in ups and downs, which facilitate drainage. Under the superintendence of my friend the Marchese di Casalotto, formerly mayor of the city, and now deputy in the Italian parliament, fresh improvements have been made. The streets have been widened and partially levelled, provided with subways, and paved, in the admirable Italian fashion, with lava blocks laid diagonally, which form a durable surface, free from dust and easily cleansed. The public gardens, where a military band plays daily, are charming, and command a fine view of Etna; and it is in contemplation to extend their area considerably. The neighbourhood also offers pleasant drives and excursions, many of which are recommended for invalids as lying within the sheltered district. There are several good hotels, the Grand Hotel and the Hôtel Centrale being the best; and visitors can live at moderate pension prices. Food of all sorts is good and abundant. For the water-supply the town depends on wells, which are liable to the usual contaminations; but Dr. Ughetti considers it to be fairly good. I may mention that during my stay in Catania in December I heard of some cases of diphtheria.

Aci Reale is reached in twenty-five minutes by rail from Catania, being eight miles to the north. It is near the sea, but not on the shore, and stands at an elevation of 560 feet, on another lava stream. The town contains 24,000 inhabitants, is clean, well paved, and well kept, and has a public garden, with exquisite views both of the volcano and of the sea. Just outside are the baths of Santa Venera, which, famous in the times of the Romans, have been resuscitated from oblivion by the spirited enterprise of Baron Pennisi, of Floristella, who has, at his own expense, erected a splendid establishment, in which nothing is wanting for the convenience of the bathers and drinkers. The waters are chiefly sulphurous and saline, and contain small traces of lithium and iodine. They are used as well for drinking as for external application, by means of douches, sprays, and baths, and, it is needless to add, are recommended for all the ills to which flesh is heir. Opposite to the bath establishment is the Hôtel des Bains, facing south and east, fitted up with all the comforts an invalid can require. It has excellent public rooms, and a garden adjoining; besides one hundred private rooms, each with a fireplace,

which is indeed seldom required for heat, but is acceptable in the evening to the comfort-loving Britisher. The food, especially the meat, is of first-rate quality, and the cuisine and wine irreproachable. The hotel is also the property of Baron Pennisi, who seems to aim more at the completeness of his enterprise than at any possible profits, for the pension prices, though somewhat high for Sicily (10 fr. to 15 fr. a day), cannot reimburse him for his enormous outlay; and be it told to his honour, several of the baths are set aside for the gratuitous use of the poor. I have not yet received the promised meteorological data of Aci Reale, but I understand the climate much resembles that of Catania. It is less well sheltered, but would have for some invalids an advantage in being farther from the sea.

Taormina, a long straggling village of 3000 inhabitants, lies to the north of Etna, and is reached in half an hour from the station of Giardini, which is one hour by rail from Aci Reale and an hour and a half from Messina. The town occupies a narrow plateau on the side of the mountain, 800 feet above the sea, and is protected from the north and north-east by the spur on which stands the beautiful Græco-Roman theatre, and also by the rocky hills of Mola and Monte Venere. The tramontana was blowing one day while I was there, and could not be felt in the town itself, but on passing through the northern gate and thus quitting the shelter of the Theatre-hill, I encountered the cool blast. But though Taormina stands high and is well sheltered, it cannot yet pretend to the comfort and good living of the last-mentioned towns. The hotels Timeo and Bella Veduta are clean and unpretending, and very moderate in their prices, but the food, especially the meat, is not sufficiently nutritious for invalids to thrive on. The landlord of the Timeo, an enterprising and most obliging young man, is now improving his hotel and doing his best to remedy the deficiency, and in time it may become a fit sanitarium for invalids in winter, and at present it would serve as a delightful change for some days or weeks in the spring. For the scholar and the artist few scenes can vie in interest with the view from Taormina. We see the coast-line dotted with the ruins of Ionic and Doric grandeur, all that remains of the Greek cities of Catana, of Naxos and Messene, and far off to the south can be descried Mount Hybla, of honey fame, and Syracuse, once the greatest city of Magna Græcia, before whose walls the pride of Athens fell in the famous siege. As one gazes over the blue expanse of the Ionian sea, the page of Thucydides rises to one's memory and pictures to us the white sails of the triremes of Nicias and Alcibiades approaching the shore which proved the scene of their disaster and of their destruction. For the lover of nature the grand study of Etna, half clothed in snow, the long reaches of sea separated by headlands of rare beauty, and backed by rugged mountains, lighted up at sunrise and at sunset in exquisite gradations of colouring, is a feast of real enjoyment, especially when seen from the foreground of the varied and picturesque ruins of the famous Greek theatre.

South of Catania the country becomes flat and marshy, abounding in small lakes, the haunts of wild fowl, and therefore better suited to the sportsman than the invalid. Malaria prevails here in summer, and also along the south coast of the island in the low-lying country, where the climate, as evidenced by vegetation, is still milder. Girgenti, which faces south, on this coast, occupies a splendid position, crowning the rock, which was the citadel of old Agrigentum, and this neighbourhood is unrivalled in wealth of Greek temples and classical remains; but the insanitary condition of the town, and the prevalence of malaria in the district, render it unfit for a sanitarium, though a tolerable hotel has been lately opened there.

Palermo, the capital of the island, on the north coast, has been too long known as a health resort to require description, but it is curious that with the many advantages it undoubtedly possesses it is not more frequented by invalids in winter. Situated on the shore of its beautiful harbour, and girt with the lovely plains of the Conca d'Oro, backed by a magnificent amphitheatre of mountains, its position lacks nothing in beauty, though it cannot be said to be perfect in the matter of shelter. The Monte Pellegrino screens it to the north, but as the town faces north-east, it is open to the cold winds from this quarter and even slightly to the north-west, although tempered as these currents are by passing over a wide expanse of sea, they carry with them less cold and more moisture. The high winter mean temperature—namely, 53° F.—and the freedom from great extremes, show

¹ Il Clima di Catania.

that its southern latitude compensates for its want of shelter, and the meteorology generally point it out as a mild climate, moister and more equable than the Riviera, as well as three degrees warmer. The vegetation in the rich plain on which one gazes from Monreale is most luxuriant, and the size of the lemon trees and of the exotics in the beautiful grounds of the villas and in the public gardens testify to the rare occurrence of extreme cold. Here, too, there is no lack of good hotel accommodation, and the Hôtel Trinacria, justly famed as one of the best in Europe, facing the sea, and in the town, is most excellent; while the same owners (Ragusa) have lately opened a suburban hotel near the English Church, specially fitted for invalids, on account of its better shelter, covered galleries, and extensive gardens. Food of all kinds is good, and cooking all one can wish. The pension terms are from ten to fifteen francs a day.

The town of Palermo is well kept, very gay, and rich in architectural and in mediæval antiquities; while the ex-

cursions, now that the neighbourhood is free from the pest of brigands, are almost inexhaustible for variety and beauty. The best way for invalids to reach Palermo is in the good boats of the Messageries Nationales, in about forty-eight hours from Marseilles; and there are also daily steamers to and from Naples in twelve to twenty hours.

In writing these few words about Sicily, I do not wish to give too favourable an impression of the island and its resources for invalids. There are undoubtedly drawbacks, such as the distance from England, the lack of English medical men settled in any of the above localities, and the want of many luxuries to be found in the sanatoria much frequented by the British; but Palermo, Catania, and Aci Reale possess sufficient positive advantages as winter stations to warrant their being recommended. And if they were so, most, if not all, of the drawbacks would soon disappear.

Upper Brook-street, W.

AURAL NOTES.

By A. GARDINER-BROWN, F.R.C.S. EDIN.,

AURAL SURGEON TO THE LONDON HOSPITAL, AND LECTURER ON DISEASES OF THE EAR TO THE MEDICAL SCHOOL.

IV.—A NEW STANDARD OF MEASUREMENT FOR HEARING-POWER BY COMPARISON WITH THE SENSE OF TOUCH.

There has hitherto been no way of accurately examining the power of the auditory nerve by the tuning-fork so as to enable us to record for clinical purposes the *degree* of deafness in a given case. And it is often not possible accurately to describe the details of a case for want of the means of giving an arithmetical value expressive of the sensitiveness of this nerve at different periods of its examination, or for comparison with its fellow of the opposite side of the head.

Testing the hearing-power by means of a watch or tuning-fork through the conducting apparatus of the ear is frequently unsatisfactory, and open to many objections as regards giving reliable data for diagnosis and prognosis, but, accompanied by a test such as that about to be described, the watch affords complementary information of much value.

If the surgeon takes a middle C tuning-fork (as shown in the diagram),

the greater or lesser length of this increase will be proportional to the *amount* of the obstruction.

There is occasionally to be observed an exception to this law, as also to the conducting power of the cranial bones for vibrations, but these questions and others will be discussed in the next "Aural Note."

OBSERVATIONS IN URINARY PATHOLOGY AND THERAPEUTICS.

By C. H. RALFE, M.D. CANTAB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL, LATE SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL, TEACHER OF PHYSIOLOGICAL CHEMISTRY IN THE MEDICAL SCHOOL OF ST. GEORGE'S HOSPITAL.

II. A FORM OF DYSPEPSIA USUALLY ASSOCIATED WITH AN ALKALINE CONDITION OF THE URINE.

(Continued from p. 87.)

CASE 1. — A gentleman, aged sixty, consulted me during Dr. Murchison's absence from town (August, 1874). He stated that during the past four months he had lost flesh and had suffered considerably from muscular pains, especially in the thighs, with a sense of indescribable weariness. General appearance worn; complexion sallow; con-

junctivæ slightly yellow. Complains of papitation of the heart and shortness of breath. Bowels constipated; much flatulent distension; troubled with frequent micturition, and is frequently awake early in the morning for this purpose. Physical examination elicited that there was no disease of the heart and lungs. The liver was of normal dimension, and there was no pain in the epigastric or right hypochondriac region. The urine was clear, slightly acid when passed, but became alkaline on boiling, and threw down a filmy cloud of phosphates, which redissolved with considerable effervescence on the addition of *dilute* acetic acid. The specific gravity was normal, 1020, no albumen, no sugar, and there was no excess of either alkaline or earthy phosphates, nor any trace of ammonia. The alkalescence was solely due to the presence of carbonates of potash and soda. He was ordered two-drachm doses of Carlsbad salts twice a week, and to take a mixture containing ten drops each of dilute hydrochloric acid and tincture of nux vomica. On Aug. 23rd he called, and said that shortly after commencing the treatment he began to feel better. He has lost the worn expression of countenance, and his complexion is clearer. The sense of weariness, backache, and muscular pain have disappeared, and he has regained some of his lost weight.

His urine is normal in all respects, and the tendency to frequent micturition has quite subsided. He considers himself quite well. Advised him to continue the use of the Carlsbad salts for some time longer, but to leave off the acid mixture. Saw him four years afterwards; he had been free from the symptoms ever since.

CASE 2.—A lady, aged thirty-six, the wife of a schoolmaster. Has lately been very anxious about her husband's health and that of her only child. Has lost flesh considerably of late. Suffers much from muscular pain, and especially in the legs; much backache. Bowels constipated; suffers much from flatulence. Worn, anxious appearance; complexion sallow, but conjunctiva clear. No enlargement or tenderness in the epigastric or right hypochondriac region. Heart and lungs healthy. Urine neutral in reaction; the quantity passed in twenty-four hours amounts to 800 cc. Specific gravity 1020. The phosphoric acid about normal in quantity, being 2.2 grammes. Uric acid 0.32 gramme. No ammonia present. There was no sugar; no albumen. Phosphates were thrown down on boiling, but were redissolved with violent effervescence by the addition of dilute acetic acid. The patient was ordered two-drachm doses twice a week of Carlsbad salts and a mixture containing ten-minim doses of dilute hydrochloric acid and tincture of nuxvomica. The patient improved materially under this treatment, but not so rapidly as did Case 1. It was not till she was able to leave home and its cares and anxieties for a while that the improvement in her condition became permanent.

CASE 3.—A Cambridge graduate, aged thirty-five, fellow of his college, who for some months previously had been engaged in arduous mathematical studies. Had suffered for six weeks from despondency, and a sense of indescribable weariness, backache, and muscular pains, chiefly in the legs. Has lost flesh. Bowels constipated; suffers much from flatulence. Micturition frequent; is roused often in the night time to pass water. Fears that he is suffering from diabetes. On physical examination his organs were found healthy. Urine normal in appearance, slightly alkaline in reaction, throwing down on boiling a cloud of phosphates, which cleared up with considerable effervescence on the addition of dilute acid. Phosphoric acid normal in quantity. No albumen; no sugar. No carbonate of ammonia. Ordered two drachms of Carlsbad salts two mornings in the week and a mixture with ten-minim doses of dilute hydrochloric acid and nuxvomica. In three weeks' time he reported himself quite well.

CASE 4.—A gentleman, aged sixty, whom I saw during Dr. Murchison's absence from town. Had spent many years of his life in India, in a Civil Service appointment. Has lately been losing flesh, and suffering much from weariness, with muscular pains in limbs. Bowels constipated, with considerable flatulence. Sallow complexion, micturition frequent. Urine alkaline; phosphates normal, no sugar, no albumen, no carbonate of ammonia. On boiling, the urine deposits phosphates, which clear up with effervescence on the addition of dilute hydrochloric acid. Ordered Carlsbad salts and a mixture, with dilute hydrochloric acid and nuxvomica. A fortnight afterwards he reported himself as much better, and in a month he wrote to say he was quite well.

The remaining cases presented similar conditions, so that it is unnecessary to quote them in detail. There was loss of weight, weariness, constipation, flatulence, frequent micturition, more or less sallowness of complexion. Urine alkaline, neutral or faintly acid, effervescing on the addition of dilute acid, with no increased elimination of phosphates nor any trace of ammonia or ammonium carbonate. They all rapidly improved under the same treatment.

In the eight cases under observation the alkalescence of the urine was clearly due to the presence in excess of the carbonates of soda and potash, and to no other cause; and the inference may fairly be drawn that the dyspeptic symptoms, in the absence of any other determinable condition, were due to the presence of these salts in abnormal quantities in the blood.

At present we know very little with regard to the effect alterations in the reaction of the blood have upon general nutrition and the metamorphosis of tissue. The blood, we know, has a constantly alkaline reaction during life; and it is probable that in health the intensity of this reaction is pretty constant, and considerable variations are followed by functional disturbance. This is admitted in the case of lithæmia, when lithic acid is either formed in excess or accumulates in the blood, owing to insufficient oxidation in the system or defective elimination by the kidneys. In scurvy,

too, it is probable¹ that the primary change that occurs is a chemical one, due to a diminution in the alkalinity of the blood caused by an increase of acid salts (chiefly urates) and the withdrawal of salts having an alkaline reaction (the alkaline carbonates derived from the vegetable constituents of the food). Experiments made on animals to reduce the alkalinity of the blood, or to neutralise it, have all ended sooner or later in the death of the animal, and the changes observed in the blood and tissues after death are identical with those found in bodies of patients dying from scurvy. Thus Hoffman,² who fed pigeons for a considerable time on food yielding only an acid ash, found that not only did the post-mortem changes resemble those of scurvy, but the symptoms preceding death were exactly alike—namely, great feebleness, tremor, and failure of the heart's action. It is, therefore, not unreasonable to suppose if diminution of the alkalinity of the blood produce such definite results that an increase in the other directions should also cause a disturbance of healthy nutrition. No definite experiments have been made in this direction on animals, but I have frequently observed that a large dose of an alkaline carbonate taken on an empty stomach, when in health, produces almost immediately a feeling of malaise, headache, and for a time frequent and copious urination.

The causes that may lead to an undue accumulation of alkaline carbonates in the blood can be thus summarised.

(a) *Feebleness with which the respiratory act is performed leading to the accumulation of carbonic acid in the system, and its combination with the alkaline oxides of potash and soda.* It is probably this condition that accounts for the alkaline state of the urine so frequently met with in convalescence from acute diseases. In these cases it will be observed the urine generally effervesces on the addition of dilute acid. Care, anxiety, overwork, &c., by inducing nervous exhaustion, tend to diminish the exhalation of carbonic acid, and lead to its accumulation in the system.

(b) *Accumulation of alkaline carbonates in the blood may be produced by long-continued respiration of impure air, and this is probably the cause of the languor experienced after being exposed for a while to the impure air of churches, theatres, &c.* It may also account for some of the weariness complained of by business men after a day's confinement in close, ill-ventilated offices.

(c) *Functional derangement of liver, attended with diminished secretion of bile.*—In the cases related it is probable that functional derangement of the liver was partly the cause of the increased alkalinity of the urine. The constipation, flatulence, and sallow complexion noticed in all show that bile was not passing freely into the intestinal canal, and the speedy relief that followed the administration of Carlsbad salts points also in this direction. That diminished functional activity of the liver should tend to produce increased alkalinity of the blood is not to be wondered at, since bile is the most important secretion by which alkaline salts are removed from the body,³ and though a portion of the alkaline salts is undoubtedly reabsorbed into the blood from the intestine, a considerable proportion of them is discharged with the fæces. A diminished secretion of bile would lead to their being retained in the blood, and consequently eliminated in greater quantity by the kidneys.

Whatever may be the theoretical explanation, there is no doubt of the fact that alkalescence of the urine arising chiefly from the presence of alkaline carbonates of potash and soda is frequently to be met with. In some cases this condition is associated with other morbid conditions, as in chronic pulmonary affections, convalescence from acute diseases, or with excessive elimination of the earthy phosphates; but in others it appears as the only tangible pathological phenomenon present. In this latter class of cases the dyspeptic symptoms, which were causing grave anxiety to the patient, speedily yielded to treatment directed to restoring the functional activity of the liver, and improving the general tone of the system by rest and, above all, change of air. Where the condition is associated with other diseases, especially with that marked by excessive discharge of phosphates, similar treatment is generally followed by improvement, but

¹ Inquiry into the General Pathology of Scurvy. By Author. Lewis: London. 1877.

² F. Hoffman, Ueber der uebergang von frein Säuren durch das alkalische Blut in den Harn. Zeitschrift für Biologie, vii., 238.

³ It has been calculated, from experiments on dogs by Nasse, Platner, and Stackman, that a man weighing 154 lb. should secrete daily about 40 oz. of bile, which would represent a considerable amount of alkaline bases discharged into the intestinal canal in the twenty-four hours.

it is neither so rapid nor so permanent in its effect. Indeed, when in a case of simple phosphaturia we find the urine becoming more alkaline from the constant presence of the fixed carbonates, it becomes very intractable as regards treatment. Of this class of cases, as well as those which closely resemble those described by Tessier under the term "phosphatic diabetes," I hope to consider in a future communication.

A NEW INSTRUMENT FOR THE INTRODUCTION OF STITCHES IN OPERATIONS FOR CLEFT PALATE, AND OTHER DEEPLY-SEATED LOCALITIES.

By EDWARD WOAKES, M.D. LOND.,

SENIOR SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT AND CHEST.

EVERY surgeon who has frequent occasion to operate for cleft palate will agree that a simplification of the process for inserting the stitches, which is equally efficient with those commonly adopted, will, by shortening the period over which the anæsthesia has to be kept up, be a gain both to himself and his patient. The instrument, of which the following is a description, is introduced by the author to meet this want. It consists in the adoption of a shuttle in the form of a needle-point, containing an eye or slot to carry the silk or wire, A. This fits on to a slight projection or pin, standing out at right angles very near the end of one blade of a strong pair of spring forceps. Between the needle and the extreme end of this blade the latter is indented by a slit to receive the silk after it leaves the shuttle or needle-point, B. When the silk is drawn home through this slit it is carried along the outside of the blade through a groove in a projection for the thumb, C, situated at a convenient distance for making pressure on the blade when using the instrument. By this means the needle is held firmly upon the inner aspect of the blade. The opposing arm of the forceps is somewhat broadened out to support the tissues when clamped between the blades. The centre of this is bored through exactly opposite the point of the needle when the blades are made to come together. This hole, E, has a projection or flange, which fits into a notch behind the point of the needle.

It is made slightly smaller than the needle, to receive which it opens somewhat by means of a spring, the blade being split for the purpose, the right degree of tension of the spring being provided by a slide, F, which is placed in position before use. The accurate juxtaposition of the needle-point with the split-ring when penetrating the tissues is secured by the guide, D, which effectually prevents any lateral swerving of the blades. When these are closed upon a flap, the fact of the needle being caught in the ring on the opposite side is indicated by a clicking noise. The thumb is now taken off the boss, C, which releases the silk, and allows the forceps to spring open. The needle is then firmly held in the other arm of the forceps, as shown at G. A little manipulation of this arm of the instrument suffices to draw the short shuttle or needle through the tissues now perforated, and with it the silk with which it is armed. This is drawn towards the operator, a good length of silk being provided for the purpose, and when well out of the mouth, the slide, F, is drawn back, allowing the spring to open at E, the needle is then slipped out with the silk still attached. It is next readjusted at B as at first, and the slide, F, replaced in its former position. The other side of the flap is now dealt with in a reverse manner—i.e., the needle is passed through from behind. The process is thus completed, the silk being passed through each side in a much shorter time than the above details would take to read. The suture thus passed is double, but it is easy to draw one thread out, should the operator elect to tie his knot with a single thread. Several needles are furnished with each instrument, and these being threaded beforehand, are readily adjusted to the instrument

in succession, as stitch after stitch is inserted. The shuttle being left on the silk when this is used double, serves to identify each particular suture, and so facilitates the process of tying when all are inserted.

The shuttles now made for me have the eye a little further from the point than shown in the engraving. Other modifications in the instrument, suggested by experience of its use, may require to be made, but the principle of the shuttle, now introduced for the first time as a surgical appliance, will not be affected by such alterations.

The applicability of the instrument for gynecological operations, vesico-vaginal fistula, &c., will suggest itself. It is not improbable that its usefulness may extend to all cases where stitches have to be inserted in deeply-seated localities, in which manipulation with an ordinary needle adds to the difficulty of the operation. It is made by Messrs. Mayer and Meltzer, of Great Portland-street. The diagram is about one-fourth the size of the instrument.

Harley-street, Cavendish-square.

TWO FATAL CASES, BELIEVED TO HAVE RESULTED FROM SNAKE-BITE AT MOUNT ABU, RAJPUTANA, INDIA.

By G. S. SUTHERLAND, M.D., SURGEON-MAJOR,
SURGEON, RAJPUTANA POLITICAL AGENCY.

ABOUT 10 P.M. on 29th May, two native girls, aged ten and seven, were sleeping on the floor of the room of the Matron of the European Hospital, who was in bed. There was a light burning in the room. The elder girl called out that she had a pain in her right hand, as if something had stung her, and the younger complained of her skin itching. The Matron thought that some insect—a wasp or scorpion—might have bitten the one, and that the other had nettle-rash, and presently took them to their own house, about a quarter of a mile off. The elder girl carried the younger one. Their uncle, employed as a cook in the barracks, returned to her house with the Matron, and as she opened the door of the room which they had just left she saw a snake cross the floor. He then sent for the apothecary, who came and killed the snake. The cook on returning to his house found the girls vomiting; and thinking they had eaten something to make them ill, went to the bazaar, about half a mile distant, for a *baker*, reputed to have some medical skill. When he returned the younger girl was dead, and the elder died within a few minutes after. It was then about 11 o'clock, about an hour after they had begun to complain. In the morning it was reported to the magistrate that the two girls had died of cholera. No one up to this time seems to have connected their deaths with the snake that had been killed. The magistrate ordered an inquiry by the police, which resulted in the bodies being brought to me for report, with the snake. This turned out to be a full-grown specimen, thirty-nine inches long, of a very venomous species, the "*Bungarus ceruleus*" (Krait).

The back of the right hand of the elder girl was a little swollen, and near the tip of the palmar surface of the first finger the mark of a single very fine puncture was barely visible in the thick skin. After a prolonged search for the mark of a snake's bite on the younger girl, some swelling was noticed over the left collar-bone, where the skin pitted on pressure, and two very indistinctly-marked punctures were seen. On pinching up the swollen skin at the punctures a blood-stained fluid oozed from numerous points as well as from the punctures. On making an incision through the skin of the bitten parts in each case the tissues below were found stained of a claret-colour, and a dark bloody fluid oozed freely from the wounds. As the girls' uncle objected strongly to a dissection of the bodies, no internal examination was made.

The story is an instructive one medico-legally, as the evidence connecting the death of the two girls with snake-bite is entirely circumstantial. No snake was seen at the time when they were bitten, and had one not been killed shortly after in the place where they had been sleeping the cause of their death might not have been suspected, and might even have escaped discovery in post-mortem examination. The marks of the snake's fangs being so very small would cer-

tainly have escaped notice, and the amount of discoloration of the dark skins and of swelling was too slight to attract attention. The fluidity of the blood would have been observed, but might have been attributed to other causes.

I have no doubt myself that these deaths were due to the bites of a snake, most probably of the one killed, possibly of another. I may add that Dr. Spencer, surgeon to the Jodhpore Political Agency, who saw the bodies with me, was of the same opinion.

Abu, Rajputana.

ST. GEORGE'S HOSPITAL.

DISLOCATION OF THE FEMUR INTO THE SCIATIC NOTCH
IN A MAN SEVENTY-TWO YEARS OLD; REDUCTION
SEVENTY-TWO DAYS AFTER THE INJURY.

(Under the care of Mr. G. D. POLLOCK.)

FOR the following notes we are indebted to Mr. C. T. Dent, F.R.C.S., surgical registrar.

William H—, aged seventy-two, a vigorous and strong man for his age, was admitted on March 27th, 1880. Seventy days before admission, as he was walking by the side of a horse drawing some trucks laden with bricks, his foot slipped, and he fell across the metals on which the trucks were running. As he fell his legs were widely stretched apart, the right being in front of the wheels. In this position he was dragged along for some few yards before the horse could be stopped. He experienced great pain in the left hip, and was unable to support himself on the left leg, which was noticed to be much drawn up. A good deal of ecchymosis appeared about the seat of injury a few days later. No attempt at reduction had been made previous to his admission. The left lower limb was then drawn up, with shortening of one inch. By Nélaton's test the left trochanter was found to be on a higher level by one inch than the right. When standing up the axis of the left femur was directed across the lower third of the opposite thigh; the left foot rested on the dorsum of the right. Passive flexion was permitted, but no abduction was possible. The same day ether was administered. The patient was laid on a couch on the sound side, and steady extension was made by the pulleys for five minutes, first in a line at right angles to the trunk, and subsequently in the line of the new axis of the limb. Some adhesions about the head of the bone were felt and heard to give way. The shortening and deformity remained as before.

Two days later ether was again given and the patient placed in the same position as on the previous occasion, especial care being taken to keep the pelvis square with the horizontal line of the couch. On rotating the thigh the head of the bone could be distinctly felt close to or in the sciatic notch. Steady extension was made with pulleys for ten minutes. During this time several attempts were made to lift the head of the bone into the acetabulum by means of a jack-towel placed round the thigh close to the perineum. These, however, failed. The patient was turned over on to his back when it was considered that the muscles were tired out; the thigh was flexed in the abdomen and abducted as forcibly as possible. The great resistance offered by the adductor muscles was very noticeable during this proceeding. The thigh was then rotated outwards and brought down towards its normal line. At this attempt the head of the femur evidently reached only the brim of the acetabulum, and was very distinctly felt and seen to slip off again. A second attempt with rather more forcible abduction was successful, and reduction was effected with an audible snap as the thigh was again rotated outwards and brought down straight. In the various movements of the head of the bone prior to its reduction, a doubt was expressed by Mr. Pollock as to

the possible existence of some slight fracture of the acetabulum. It was difficult to decide this point accurately, and it is possible that the idea of fracture may have been occasioned simply by the rubbing of the cartilaginous surface of the head of the bone against the edge of the acetabulum. This grating sensation, which was, however, unlike that of true bony crepitus, was distinctly felt by the finger introduced into the rectum.¹ A considerable amount of swelling followed the reduction. The limb was placed in a long splint, and perfect rest in a straight position was enjoined. After three days the splint was removed. It happened that same evening that the patient became much excited, got out of bed and walked across the ward. Shortly after this the deformity was found to have returned. Five days after the former reduction ether was again given, and the bone again replaced, this time without the aid of the pulleys. A long splint was applied, and kept on for twenty-one days. He was discharged thirty-two days later, and was then able to walk well with a stick. He limped slightly, but was able to move the limb freely in all directions without pain.

Remarks.—Mr. Pollock stated that some years ago a man seventy-two years of age was admitted under his care with dislocation of the femur into the sciatic notch. He was a very spare subject, and the dislocation was caused by his simply slipping off a low stool on which he had been sitting. This was readily reduced by pulleys within forty-eight hours of the accident. But with regard to the present case Mr. Pollock felt satisfied that unless the thigh and leg had been used as a lever to act on the displaced head of the femur, the pulleys would have failed in its reduction, and that the man would have remained a cripple for life—a condition of things which, no doubt, would have been the result prior to the introduction of manipulation for the reduction of dislocation of the hip. It remains to be seen how far manipulation may be hereafter attempted in dislocations of still longer standing than the one recorded above—a question well, worthy the attention of all surgeons.

Notwithstanding a tolerably diligent search through the works of various authorities, no parallel case can be found. In the *Medical Times and Gazette*, December, 1865, p. 661, Verneuil relates a case of fracture resulting from an attempt to reduce a pubic dislocation in a man eighty-one years of age, after many attempts at reduction had failed. Sir A. Cooper relates a similar case occurring during manipulation. Bigelow (*op. cit.*, p. 55) relates the case of a woman at twenty-seven, where reduction was effected after eight months. Unfortunately, in many of the cases recorded the age of the patient is not mentioned. There can be no doubt that the case of W. H— described above is of a very exceptional character.

ST. PANCRAS WORKHOUSE INFIRMARY.

A SUCCESSFUL CASE OF OVARIOTOMY.

FOR the following notes we are indebted to Dr. William Dunlop, resident medical officer.

E. R—, aged twenty-one years, single, was admitted on June 15th, 1878, on her own statement that she was in labour. She was not confined, however, until August 30th, and she made a good recovery. About five weeks after her confinement she began to suffer from abdominal pain, and an abdominal tumour was then discovered in the right iliac region, which for the next few weeks kept steadily increasing in size. About the middle of November of the same year she was seen by Dr. Edwards of Gloucester-crescent, Hyde-park; and as an accurate diagnosis could not be made then he saw her again in six weeks, when he was of opinion that the case was one of unilocular ovarian cyst.

On May 12th, 1879, ovariectomy was performed by Dr. Edwards. An incision, three inches in length, was made in the middle line between the umbilicus and the pubis, and

¹ As regards the probable complication of fracture it may be remarked that, considering the length of time that had elapsed since the accident, it is possible that, if fracture of the acetabular rim took place at the time of the accident, union may have occurred. Thus, Maisonneuve relates a case of dislocation in which a fragment of a broken acetabulum had in twenty-seven days united with the rest of the rim so firmly that the fracture could hardly be discovered. (*Rev. Méd. Chir.*, tom. xvi., p. 48.) In a case of Sir B. Brodie's, of twelve weeks' standing, failure to reduce a dorsal dislocation was attributed to fracture of the acetabulum. (*THE LANCET*, vol. xxiv., p. 671.) On the other hand, cases have been recorded (cf. Bigelow on Dislocation of the Hip, p. 144) where in supposed fracture of the acetabulum no crepitus could be felt.

the tumour, being exposed, was tapped, and its fluid contents drawn off. The walls of the cyst were then removed, and this had to be done with considerable care, as there were adhesions along nearly the whole of the anterior surface of the tumour, and also some recent adhesions to the broad ligament. The tumour having been removed, the pedicle was found to embrace the right ovary. The pedicle was secured by a clamp, and separated by the hot iron. There was little hæmorrhage during the operation. The wound was closed by two deep catgut carbolised sutures and three superficial wire sutures; it was dressed with lint and carbolised oil and prepared oakum, the abdomen being supported and the dressings kept in place (including the clamp) by strips of porous plaster. Over the whole was placed a layer of cotton-wool and three layers of broad flannel binding.

In its subsequent course the case presented no symptoms to cause any anxiety. The patient made a gradual and excellent recovery. On May 24th the clamp fell off. She was able to sit up on June 5th, and shortly afterwards was sent down to Margate, where she became perfectly well.

The tumour, which was a large one, was removed through a very small opening. A very small quantity of stimulants was given throughout the case. No ice was used at any time, and the operation was conducted on antiseptic principles.

LEEDS' GENERAL INFIRMARY.

CASES OF INJURY TO THE EYE.

(Under the care of Mr. OGLESBY.)

THE history of the following three cases is interesting from the similarity of accident and the results of each.

CASE 1. — A young man, working as a mechanic, was struck in the left eye by a piece of metal, which had entered through a wound involving the lower two-thirds of the cornea on the left side. The wound, although large, had healed by first intention, and, except a slight redness of the conjunctiva, no objective symptoms pointed to the serious nature of the case. The subjective symptoms were pain and dimness of vision; tension of the globe — 2. The right eye was healthy, and not in the least affected sympathetically. Careful examination failed to detect any foreign body within the eye, and it was surmised that the piece of iron had struck the cornea obliquely, and after wounding it glanced off. This, the man said, was not so, as he could distinctly feel the foreign body move when looking upwards. Mr. Oglesby decided to remove a large piece of iris corresponding to the wound in the cornea. Iridectomy having been performed, it was hoped that the iron would present, but such was not the case. The iris forceps were then gently introduced and search made. The blades of the forceps, after slight separation, were pressed directly downwards and then closed. The closing of the blades was interfered with by the edge of the foreign body, which was evidently lying across the fundus, and not placed vertically as supposed. A second attempt was more successful, and after the use of considerable force, a piece of iron resembling in size and shape an ordinary pin was removed. A considerable quantity of lens matter escaped. The immediate treatment consisted in the frequent instillation of atropine and the constant application of cold. Mr. Oglesby predicted that, from the force which it was necessary to use in the extraction of the iron, little chance remained of saving the eye, and that extirpation must soon be resorted to. Three days after the operation the eye was examined, when the following symptoms were noticed: redness of the second degree; pupil more or less filled by opaque lens matter; wound of cornea healthy in appearance; tension — 2; pain of the second degree; intolerance of light but slight. From this day the eye improved rapidly, and when last seen (May 29th) it was free from inflammatory troubles, and vision so far improved as to enable the man to recognise the features of his friends. During the whole of the case no single symptom of sympathetic ophthalmia appeared. The successful termination of this case was due in a great measure to the energetic treatment of the resident assistant, Mr. Norman Porritt, who watched the case closely, and on several occasions applied the artificial leech with marked benefit.

CASE 2 presented itself during the same week the above case was admitted. The history was similar in many particulars to that of the first patient, the main difference being the bulging of the iris, indicating the position of the foreign

body. It was evident that the piece of iron had passed through cornea and iris in a direct line. The tissues generally had suffered but slightly, the objective symptoms being redness degree No. 2; intolerance of light degree No. 1; tension — 1; pain degree No. 2. No ciliary zone. Iris apparently healthy. The sound eye not sympathising. Mr. Oglesby decided to, if possible, extract the foreign body without removing any portion of the iris. A section of the cornea, one line from the sclero-corneal junction, and immediately over the distended or bulging part of the iris, was decided upon. This having been done, the iris forceps were introduced through the section then made, and then pressed gently on the iris, and at the same time the blades were separated. This procedure was followed by the appearance of the foreign body squeezing its way through the rent in the iris, which had been made by its entrance. The blades of the forceps were then closed, and the iron grasped; gentle traction proved of little avail, so firmly was it imbedded in the structure of the iris. Very considerable force had to be employed before it could be dislodged. It was afterwards noticed that the piece of iron—which resembled an ordinary tin tack in shape and size minus the head—had a serrated edge, and to this fact is due the resistance experienced. Mr. Oglesby much feared that after such rough treatment of the iris that inflammation of the ciliary body would result, and possibly sympathetic mischief if the man were made an out-patient and no proper supervision exercised. The treatment was the same as in the last case. Again much good was obtained by the application of the artificial leech freely used by Mr. Porritt.

The result proved contrary to anticipation, no single untoward symptom resulting. When last seen the eye was quiescent; the pupil was fairly active. There was opaque capsule in the lower segment; vision was good for ordinary purposes.

CASE 3.—Whilst Cases No. 1 and No. 2 were as yet undergoing treatment, No. 3 was admitted as an in-patient. He was a joiner by trade, and had a short time previously been struck in the left eye by a splinter of wood—a piece of which remained as a foreign body within the eye. When first seen there was evidence of a foreign body partially concealed by the fibres of the iris. The wound in the cornea was only partly healed, and a considerable breach existed, through which the aqueous humour passed. There was evidence of intense iritis, the pupil was blocked by soft lens matter from rupture of the capsule. Mr. Oglesby decided to remove a large piece of iris, and if possible the foreign body, at the same time. So soon as the iris was seized in the forceps pus in large quantities bathed its anterior surface, and gave evidence of universal mischief. There was considerable difficulty, as in the other cases, in extracting the foreign body, which proved to be a piece of rough wood, a quarter of an inch in length and the eighth of an inch in breadth. Mr. Oglesby felt confident that the ultimate result would be extirpation. This proved to be so, as all treatment failed, even the artificial leech, although applied twice or thrice, and Mr. Oglesby removed the eyeball at the end of four days.

The history of these cases goes far to prove how tolerant of injury the human eye is, and how readily it responds to remedial measures properly selected. The artificial leech is invaluable in certain cases when applied with judgment and skill, and was probably the means of saving the eyes in the first two cases. Mr. Porritt has most thoroughly worked out in detail when and how to apply it, and to him Mr. Oglesby is much indebted for the success which has attended the treatment of many apparently hopeless cases.

Reviews and Notices of Books.

A History of Classical Greek Literature. By the Rev. J. P. MAHAFFY, M.A., Fellow of, and Professor of Ancient History in, Trinity College, Dublin, &c. Two vols. London: Longmans, Green, and Co. 1880.

AS Mr. Mahaffy himself hints, a history of Greek literature has probably become too great a task for any single man to accomplish adequately. Not only is a large and intimate acquaintance with the many and various Greek writers indispensable, but the vast and complicated literature of commentary and criticism must also be taken into account. It would be unreasonable to expect to find in any

one person a combination of all the qualifications for such a task. Mere scholarship is only one of these. A wide and exact knowledge of the various departments of philosophy and of science must be superadded. One of the chief merits of Mr. Mahaffy's work is that it combines in useful proportions a sufficiently correct knowledge of the original Greek authors, and a familiarity with the best English and foreign criticisms thereon.

For the average reader, the second volume, which deals with the Greek prose writers, will be the more serviceable; though scholars may perhaps prefer the first volume, which is devoted to a consideration of the Greek poets. Those whose critical capacities may not be satisfied with the intricacies of the Homeric question, as discussed at the beginning of the first volume, will find plenty of scope in the learned Appendix A, by Professor Sayce, "On the Language of the Greek Epic Poets, and more especially of the 'Iliad' and 'Odyssey.'" This is a feat of learning far beyond the ordinary reader.

We have already hinted at our preference for the second volume; and in this volume it is only natural for a medical reader to turn to the chapter on Herodotus and Hippocrates. Herodotus is not only the Father of History (though Mr. Mahaffy thinks this title belongs by right to Hecataeus of Miletus), but he is in a sense the Father of the History of Science. By travelling through Greece and foreign countries, Herodotus made himself acquainted with the manners, customs, and learning of many nations. But for Herodotus we should know much less than we now do of the science in Egypt and the ancient East. Numerous incidents are related by him which give us an insight into the state of the science and art of medicine and surgery in Greece, Egypt, and Persia five hundred years before the Christian era. It is unfortunate that Herodotus, who has done so much to perpetuate the memorials of early medicine, should, during his lifetime, or shortly after, have had a virulent detractor in Ktesias, the private physician of Artaxerxes at the battle of Cunaxa.

In discussing the writing of Hippocrates Mr. Mahaffy for the most part follows M. Littré, both in his criticisms and in the classification of the genuine Hippocratic writings. "The style of Hippocrates," says our author, "is nervous, exceedingly compressed, and at times obscure from brevity; but, on the other hand, profoundly suggestive, picturesque, and full of power and pathos. He uses poetical words and images freely, but always to increase the fulness of his meaning, never for mere ornament. He is far terser in thought than Thucydides, though he resembles him in shortness of expression; indeed, he more resembles Heraclitus than any other Greek prose writer." This criticism, though more sweeping, agrees in the main with that of the only competent scholar the medical profession in England has produced in recent times—namely, Dr. W. A. Greenhill. This gentleman, in his excellent article on Hippocrates in Smith's Dictionary of Greek and Roman Biography and Mythology, says, "The style of the Hippocratic writings, which are in the Ionic dialect, is so concise as to be sometimes extremely obscure; though this charge, which is as old as the time of Galen, is often brought too indiscriminately against the whole collection, whereas it applies, in fact, especially only to certain treatises which seem to be merely a collection of notes, such as 'De Humoribus,' 'De Alimento,' 'De Officina Medica,' &c. In those writings, which are universally allowed to be genuine, we do not find this excessive brevity, though even these are in general by no means easy."

Mr. Mahaffy's history embraces only the purely classical Greek literature, and does not, in consequence of stopping at the fourth century B.C., include what has been called the literature of erudition and science. The literature of the Alexandrian school and all that followed it

is thereby necessarily excluded. But within its limits Mr. Mahaffy's work is very complete. It is emphatically a trustworthy guide; and the addition of short bibliographical notices at the end of the sketches of the authors enhances the general utility of the work both for the student and the general reader.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

Session 1880.

Thursday, July 15th.

THE Council reassembled at the usual hour, Dr. Acland, President, in the chair.

Mr. TURNER moved a resolution to the effect that the bodies conferring licences in Dental Surgery be requested to furnish each year a statement of the nature of the examinations, whether written, *visà voce*, or practical (one or all of the three), and of the number of candidates for their licences, showing the numbers passed and rejected.

Dr. STORRAR seconded the motion, which was agreed to.

A memorial was received from the Association of Surgeons Practising Dental Surgery with reference to Dental Registration, and a counter memorial on the same subject from the British Dental Association.

A letter was also received from the Hon. Secretary of the British Dental Association, transmitting a corrected list of persons who, in the opinion of counsel, were liable to have their names erased from the Dentists' Register, on the ground that, not being registered in the Chemists' and Druggists' Register, they had illegally declared themselves to be engaged in the *bonâ-fide* practice of dentistry with pharmacy.

Dr. PITMAN proposed, "That the foregoing letter from the British Dental Association, and other communications received on the same subject, be referred to the Dental Committee, to ascertain the facts as to the several cases referred to in such letters."

This was agreed to, and it was also resolved, "That certain persons having requested that the words 'with Pharmacy' be omitted after their names from the Dentists' Register, it is recommended that the Council refer all such cases to the Dental Committee to ascertain the facts in each of such cases."

Dr. QUAIN moved, "That the opinions on the subject of Dental Registration specified in the minutes of the Executive Committee for Nov. 28th, 1879, be referred, with all preceding documents, to the Dental Committee." He said it was desirable that the opinions of counsel, which in some respects were contradictory, should be laid before the Dental Committee for their guidance, but he thought they ought not to be published.

Dr. PITMAN seconded the motion.

Dr. STORRAR supported the motion, but did not agree with Dr. Quain as to the desirability of withholding the opinions of counsel from publication. He disapproved of their being retained as secret documents.

Mr. SIMON thought that as the opinions were not before the Council, they ought not to be sent to the Dental Committee.

THE PRESIDENT said there was a doubt in the minds of some members as to the precise functions of the Dental Committee; and he would ask Mr. Ouvry, the solicitor of the Council, who was present, to make a statement on that subject.

Mr. OUVRY said that the thirteenth and fourteenth clauses of the Dentists Act gave directions as to the mode of erasing names from the Register, or restoring names that had been struck off; and the fifteenth clause directed the mode in which that operation had to be carried out. It was the opinion of Mr. (now Justice) Bowen, that the Dental Committee could not initiate anything, but that the Council should refer any proposal to erase or restore a name to the Committee to ascertain the facts; and on the basis of the facts so ascertained and reported the Council would have to

form its judgment. The question of publishing the opinions of Council was in the discretion of the Council, but he thought it might be embarrassing to do so.

The question of the propriety of publishing the opinions of Council was then discussed, and it was ultimately resolved that the opinions should be read, but that strangers be requested to withdraw. The Council deliberated for some time in private. In the course of the private sitting it was moved by Dr. STORRAR, and seconded by Dr. HAUGHTON, "That the cases relating to the Dentists' Register, submitted for the opinions of Mr. Bowen and Mr. Fitzgerald, and their opinions thereon, be inserted in the Minutes." The motion was negatived, and it was then resolved, on the motion of Dr. A. WOOD, and seconded by Mr. SIMON, "That the opinion of counsel be taken as to whether the Council can delegate to the Executive Committee the initiation of proceedings by the Dental Committee under Section 15 of the Dentists Act, and that if the opinion of counsel be that such power can be so delegated, the Council hereby delegate the same to the Executive Committee." It was also resolved that the case of Mr. John Hamilton be referred to the Dental Committee, to ascertain the facts, and report thereon forthwith to the Council.

On the readmission of the public, Mr. SIMON proposed, "That, in Section 3 of Chapter I. of the Council's Recommendations on Education and Examination, the List of Bodies from which testimonials of proficiency in Preliminary General Education may, in the opinion of the Council, be properly accepted by the licensing authorities under the Medical Act, be amended by omission of its Part II.: this amendment to take effect on and from the 1st of January next: and that notice be forthwith given to each licensing authority that, after the end of the present year, the examinations mentioned in Part II. of the aforesaid List will not be regarded by this Council as satisfactory for the purposes of the Medical Act." He said the object of the Council was as far as possible to secure that all who came into the profession should be well-educated gentlemen, and that the test should be applied in the same way as among other classes of society. A man who entered the medical profession should be able to mix as an equal with other educated persons. Of course that did not mean that every one should be an M.A. Grades of education must be recognised; but what was required was a standard which, so far as it went, should be applicable to all classes. To secure that object the test ought to be applied, not by medical authorities, nor by boards under medical influence, but by bodies generally conversant distinctively and professedly with common school education. He wanted the standard to be as high as could fairly be expected, and that whenever it was fixed by the Council it should be strictly enforced. Would that be done by the professional bodies? His own opinion was that it could not be enforced. The question was not what amount of Latin and algebra and geography, and other subjects, was necessary to make a member of the Royal College of Surgeons of England, Scotland, or Ireland, but what amount of education would make a well-educated gentleman; and the fear was that if the test were in the hands of the medical authorities it would be applied in too special a sense. From first to last the Council had held but one language on this subject. When first the preliminary examinations were instituted they had to recognise an absence of common examining boards, and therefore, provisionally, certain examinations by the medical bodies were accepted. It was understood that that arrangement was exceptional; it was simply agreed to for want of a better. In 1877 very decided action was taken, chiefly on the motion of Dr. Humphry, who compiled the report of the Executive Committee on the answers received from various licensing bodies. Upon the report the subject again came under the consideration of the Council, and it was decided that it was desirable that the examinations in general education should be left to the national educational bodies. In 1879 the subject was submitted to the several branch councils, the result to be brought before the Council at the present meeting. The report of the Branch Council for England contained this very important sentence: "They do not believe that the preliminary examinations will ever commend themselves to the confidence of the profession or the public till they cease to be conducted or controlled by medical corporations or medical faculties at the universities." The matter was now brought up for decision, the Council having before them the reports of the branch councils. It was farcical to keep on repeating to the educational public that they recommended things to be done at some indefinite

future day. So many years had passed since the Council first decided upon this subject, and so many non-professional examining institutions that could be trusted had sprung up, that he thought the time had now arrived for closing the question. As regarded the terms of his resolution, he wished to point out that it was not, and could not, be imperative. Those who read it carefully would see that it only put in an unambiguous form what he believed to be the decided wish of the Council. They should cease to give to what they considered a bad system the sort of sanction which was implied by continuing the Part II. of their Recommendations. They had gone on long enough. Other institutions had been established which would fulfil all the purposes, and now was the time when the Council might distinctly say that the old system could no longer be considered satisfactory. Of course the motion would not have the force of law, but it would have the weight that the opinion of the majority of the Council always had with the minority. Those who believed the existing system to be wrong were at present conniving at its continuance. The Council ought not to speak with two voices; there ought to be no uncertainty about their views. It was not a question whether or not the examinations at particular institutions were well conducted, but it was a question of the tendency of the system, and from first to last it had been the opinion of the Council that that tendency was bad. He now asked them to pronounce an unmistakable opinion. In one sense such a vote would be obligatory, for he believed that every one at the table would feel that an honest, large, clear majority in favour of what had throughout been the policy of the Council ought to be deferred to. It was not an attempt to exercise any improper control, but only an endeavour to bring the absolutely unquestionable opinion of the Council to bear on the continuance of the present system.

Dr. STORRAR seconded the motion.

Mr. MACNAMARA said it had long been the dream of his life to see the day when everyone entering the ranks of the profession should be possessed of a degree in arts of some university, for that would be the true way of raising the standard of the profession; but in the present condition of public wants he felt that that desire was Utopian. One of the reasons why Mr. Simon wished to take away the examination in arts from the corporations was that he felt that the corporations were influenced in their verdicts by their desire to secure the students from their professional ranks. Were not the universities open to the same charge? The two universities in Ireland boasted of their large classes. But on behalf of the corporations he repudiated the charge, as he was sure the representatives of the universities would do. The College of Surgeons in Ireland held examinations in arts, and he believed the examination to be as efficient as the Council could deem it desirable at present to require from students; and to prove that that college could not be in the slightest degree influenced by the desire to swell their medical student list he would mention that the examiners did not live near any medical school. They came to Dublin from provincial towns to conduct the examinations. How then could they be influenced by the sordid wish to swell the medical classes, with which they had no connexion whatever? It was now proposed to deprive the bodies of their chartered right by a recommendation of the Council, and his college, for one, would challenge the Council to go before the Privy Council and prove that that college was incompetent to perform its duty. The passing of the resolution would do a great injustice to the students in Dublin. For submitting themselves to the public entrance examination at the University of Dublin they would have to pay £16 each, instead of one guinea, which they now paid at the College of Surgeons. The Queen's University occupied a lofty position from the education it gave its students, but in order to pass the entrance examination they would have to go to Galway, Cork, or Belfast. Mr. Simon wanted the Council to settle the question now, but it was utterly impossible that it could be settled so far as the College of Surgeons was concerned, and he implored the Council not to pass recommendations that they knew would be treated with the most thorough contempt. They were all anxious to respect the recommendations. The College of Physicians in England and the College of Physicians in Ireland had already adopted the suggestion of the Council, and no longer conducted preliminary examinations. The College of Surgeons of England had taken the matter into their serious consideration and

had not decided against it; they were on the whole in favour of it, but at present they saw difficulties in the way of carrying out the recommendation. If the Council passed such a resolution as Mr. Simon had proposed, he feared that they would interfere with the progress of that very action which they desired, and it was not unlikely that it would be resented by the College of Surgeons of England. In such a matter they ought to proceed carefully, quietly, and slowly. The principle of the resolution he thoroughly assented to, but its wisdom he greatly questioned. The result of passing it would be that the Council would not admit upon its register the examinations of these bodies, though they had no power to prevent them; and if he would go there and make a report to the Council on what he saw, he would certainly not condemn the examinations. It might be that in a short time the Irish bodies might be in a position to carry out the recommendation of the Council, when they saw how the Board of Intermediate Education worked, but it had only just been started. The College of Surgeons was quite anxious to get rid of these examinations, for they were inconvenient, but it was utterly impossible for them to discharge their duty at present without them.

Dr. HUMPHRY said his own feeling was that, as a matter of principle, it was desirable that these examinations should be left to the great national educational and examining bodies. The universities, with scarcely an exception, recommended that that principle should be carried out; but if something was recommended by the Medical Council which was thoroughly impracticable what could the College of Surgeons do but implore to be brought before the Privy Council, and then probably the Medical Council would not be quite satisfied with the result. Mr. Simon said that the Council believed the present system to be bad, but he altogether protested against the statement. What grounds had they for believing so? It was all very well for a lot of gentlemen sitting around that table to say they believed so and so; but the Council had a duty imposed upon them which they had neglected to perform. If they visited the examinations they would be in a position to say whether they believed them to be good or not; but until then they were not justified in saying that they were bad. He was sure that the Irish members would be charmed to see Mr. Simon in Dublin. When the students' certificates came up for registration, either the Council would accept them, and so act in opposition to their own resolutions, or the registration would become a thing of naught. There was no likelihood of the Privy Council confirming their view if they appealed to it, for the Medical Council was only a Council of medical education and registration. He very much doubted whether the Medical Act gave them any power in the matter of general education, and in his opinion they would act most unwisely, and probably counteract the very end they had in view, if they passed such a threatening resolution as was now proposed.

Mr. TURNER said he entirely coincided with the views expressed by Dr. Humphry; and although he would like to see these examinations in the hands of the national educational examining bodies, he thought the time had not arrived for passing such a resolution as that which Mr. Simon had proposed. The Council should trust to the powers of moral suasion, and not enact such a peremptory resolution as was now submitted to them. Mr. Simon had not sufficiently taken into consideration that the Council had no power whatever to insist upon the registration of medical students, and there was nothing to prevent any corporate body admitting to its examinations a student who was not registered.

Dr. BANKS said he quite agreed that the examination in Arts should be conducted by men who were daily conversant with the subjects in which they examined, but at the same time he thought that the Council should confine itself to what Mr. Turner had called "moral suasion."

Dr. WOOD said that the different licensing bodies had to so large an extent adopted the various recommendations which the Council had passed, that when they made a strong objection in any single case the Council ought to hesitate before they applied coercion. The result of the present resolution would be to disfranchise the Royal College of Surgeons of England, the Apothecaries' Society of London, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, the Royal College of Surgeons of Ireland, and the Apothecaries' Hall of Ireland. Considering that those bodies had been so willing to act according to the recom-

mendations of the Council in times past, he did not think anything would be gained by putting them in hostility to the Council. The proper way to coerce them would be to call upon them to desist from the examinations, and if they refused to do so to appeal to the Privy Council. He was sure that the Scotch members were quite willing that Mr. Simon should come to Edinburgh and report upon the preliminary examinations there.

Dr. ROLLESTON said it appeared to him that the licensing bodies had already put themselves into a position of hostility against the Council, because for the last nine or ten years the Council had been recommending what was now proposed, and the bodies had not adopted it. He thought it would be better to enlarge the time to January, 1882. It was not the proper business of the Council to deal with general literary subjects, and they could not do so without being suspected; and the present system put the corporations in a position of temptation.

Dr. PITMAN said that the majority of the Council had hitherto only expressed their opinion that it was desirable that the examinations should be left to the universities; but what was desirable and what was possible were two different things. It was not possible to carry out what Mr. Simon proposed. The consequence of adopting the resolution would be that the bodies which objected would continue to conduct their examinations in general education, and the students would not be registered by the Medical Council, but when they received their qualification to practise they could not be refused.

Sir JAMES PAGET thought that a large portion of the time of the Council had been wasted in accusations and defences. In his opinion the motion was simply impracticable, and as indiscreet as it was impracticable. The wishes of the Council were being complied with everywhere, and it was absolutely untrue to say that there was anything like a general opposition in the College of Surgeons to the Medical Council. If the resolution was agreed to, what was to be done with the 600 or 700 students who came up to the College of Surgeons for their preliminary examination every year? The whole profession was at one upon the view that the preliminary examination should be gradually improved, and as time went on entrusted to bodies which were not engaged on professional subjects; but if anything could obstruct the course of things in the College of Surgeons it would be such a mandatory resolution as that which was now before the Council.

Dr. STORRAR said, though he had seconded the motion he would recommend Mr. Simon to withdraw it after what had been said by Dr. Humphry and Sir James Paget.

After a very brief discussion, Mr. Simon expressed his willingness to withdraw the motion; but as Dr. Wood objected to the withdrawal, it was put to the vote, and the permission to withdraw was given by a considerable majority.

On the motion of Mr. TEALE, the Council resolved to instruct the Executive Committee to consult an expert with regard to improving the ventilation of the room in which the Council met.

The Council then adjourned.

Friday, July 16th.

At this the last meeting of the Council

Mr. TURNER asked the President if he could furnish the Council with information why the Navy Medical Department had ceased to furnish a statement of the results of the examinations for admission to the Medical Department of the Navy.

The PRESIDENT said he had received a letter from the First Lord of the Admiralty stating that he could not find that the Medical Council had asked the Admiralty to furnish the information, but there was not the slightest objection to their being furnished with the same information as was given by the Army Department.

Dr. HAUGHTON asked the President to take into his consideration the propriety of holding the usual annual meeting of the General Medical Council during the Easter recess.

The PRESIDENT replied that care was always taken to ascertain what time would be most convenient for the Council to meet. He had been told by more than one member of the Council that it would be very desirable to have a fixed time for the meeting of the Council, but in that opinion he could not concur. Every care would be taken to ascertain what was the most convenient time, and to

that end it was necessary to obtain information from various parts of the country with regard to the state of business.

Mr. MACNAMARA asked the President whether he could communicate to the Council the names of such of the authorities mentioned in Schedule A to the Medical Act as accept, *ad eundem*, either in whole or in part, the "previous medical examinations" conducted by other bodies, and, if so, whether he would be good enough to give the Council the information, and to state in each case to what extent the acceptance goes.

The PRESIDENT said there was no information in the office which enabled him to answer the question.

A communication was received from the Royal College of Surgeons in Ireland in regard to Mr. John Hamilton stating that that gentleman's diploma as licentiate in dental surgery had been cancelled. A report was also received from the Dental Committee with reference to the case of Mr. Hamilton, upon which a motion was submitted from the chair to the effect that the qualification of licentiate in dental surgery of the Royal College of Surgeons in Ireland appended to the name of Mr. Hamilton in the Dental Register be erased, and the motion was unanimously adopted.

Mr. MACNAMARA proposed and Dr. HAUGHTON seconded the motion, that Mr. Hamilton's name should be removed from the Register; but it was pointed out by the President that that course could not be adopted without previous inquiry, and the motion was accordingly withdrawn.

It was then resolved, on the motion of Dr. A. Wood, that the case of Mr. Hamilton be referred for inquiry as to the facts to the Dental Committee.

Dr. STORRAR said that there were many cases referred to the Dental Committee, and he thought it would appear that many of the persons concerned richly deserved to be struck off the Register; he therefore suggested that the Council should meet again on dental business before the end of the year, so that the names in question might not appear in the Register for 1881.

Mr. MACNAMARA moved, "That all such bodies the preliminary examinations of which cannot be visited by this Council, be removed from the list of bodies receiving its sanction." There were on the list seventy-two different and distinct examining boards, the testimonials of which were recommended by the Council to be of service, but he strongly suspected the only knowledge of these examining boards on the part of members of Council was derived from hearsay. The object of a preliminary examination was to secure that a medical man should have such education in general and polite literature that he should be able to act the part of a gentleman in the course of his profession. That would, of course, include a thorough knowledge of English, and he did not believe that was given in some of the foreign educational bodies. Even if the student had passed such an examination it could be no great hardship to ask him to pass a second examination before one of the English examining bodies.

Dr. HAUGHTON seconded the motion. No doubt that some of the bodies in the list gave a thoroughly trustworthy examination, but many of them ought to be removed.

Dr. STORRAR asked Mr. Macnamara to withdraw the motion for the present session. He had himself looked over the list, and, having regard to the slight knowledge possessed by the Council of many of the bodies, he thought it might be advisable to sweep away the list altogether, and leave it to the Branch Councils of the three kingdoms to decide upon the admission of cases.

The motion was then withdrawn.

Mr. TURNER moved, "That the 'Gymnasial Abiturienten Examen' in Germany, and the corresponding Examinations in other Continental countries, required for admission to their respective universities, be accepted as qualifying for registration as a medical student." Mr. Turner explained that this was in reality the entrance examination to the German universities. It included a thorough knowledge of German and Latin; a sufficient knowledge of Greek to enable the student to read any author in prose or verse without preparation; a general knowledge of history; French, mathematics, geometry, algebra, the elements of natural science, and the elements of logic. These subjects were compulsory, and altogether this examination was on an infinitely higher platform than the preliminary examination which the Medical Council during the present session had considered all that was necessary for entrance to the study of the profession in this country.

Dr. ROLLESTON seconded the resolution, which was agreed to.

Dr. FERGUS moved, "That the following additions be made to the Council's Standing Orders or Recommendations:—1. During the month of January in each year, the examining bodies which are recognised by the General Medical Council as capable of giving certificates of proficiency in the subjects required for preliminary examination shall make a return to the General Council according to a prescribed form, stating the number of the candidates who, in the preceding year, have passed the respective examinations of such bodies, and the number of those who have been rejected at such examinations. 2. All preliminary examinations shall be by written papers, and the answers shall be regularly numbered and preserved by each body for at least two years. 3. The General Medical Council shall from time to time request that certain of the papers, both passes and rejections, shall be forwarded to its office, there to be examined either by members of Council, officials of that body, or by gentlemen appointed by the Council, or its Executive Committee. If the examiners find that there are 'cases in which decided ignorance in general education has been displayed by candidates' (Minutes, vol. xiv., p. 142) who have passed their preliminary examination, such cases shall be reported to the General Medical Council or its Executive Committee, either of which shall intimate the fact to the examining body, and request more attention in future. If laxity is persisted in, the General Medical Council shall 'represent the body' to the Privy Council. 4. A degree, either in arts or science, granted by a university or a licensing body recognised by the Council, shall be held a sufficient qualification as regards the subjects in which the holder of the degree has been examined. Subjects not covered by the degree must be passed before the person can be registered as a medical student." He said that in 1877 the Council had passed resolutions on the subject, but there had been no outcome from them and they had remained a dead letter. The bodies had not sent the answers required, possibly because no remedy had been suggested for the evil that was pointed out. With a view of providing such a remedy, he proposed the resolutions of which he had given notice.

Dr. PETTIGREW seconded the motion.

Dr. PITMAN thought that the licensing bodies would be offended if the Council resolved that they "shall make" the required returns.

Dr. FERGUS said he would alter the words to "be requested to make."

Dr. STORRAR pointed out that the London University would be unable to meet the proposed requirements, as it did not know what percentage of those who passed its matriculation passed to the study of medicine.

Dr. FERGUS said he was willing to withdraw his motion and bring it forward next session.

Dr. HUMPHRY hoped that the proposal would not again be brought forward, as it was utterly impracticable.

After a short conversation the motion was withdrawn.

Dr. HAUGHTON moved, "That the General Medical Council are of opinion that the first medical examination should include an examination in physics, meaning thereby the elements of heat, electricity, and magnetism," but afterwards consented to refer it to the consideration of a committee.

Mr. MACNAMARA moved, "That a Pharmacopœia Committee be appointed, with the view of considering and of reporting to this Council how best any future edition of the British Pharmacopœia may be brought up to the scientific standard of the present day." He said he did not wish to say a word in disparagement of the British Pharmacopœia. It was published thirteen years ago, and it was no condemnation of the work to say that it was not up to the scientific standard of the present day. Its nomenclature was behind the times, and was not to be found in any modern work on chemistry. There were numerous omissions, including antonine lozenges, chloride of barium, chloride of methylene, seidlitz powders, &c., and there were also many errors in the work. He thought that with a view of keeping the work up to the required standard, a Pharmacopœia Committee should be appointed, and should sit *en permanence* and watch the progress of science.

Dr. A. SMITH seconded the motion.

Dr. A. WOOD pointed out that there was a Pharmacopœia Committee already in existence, of which Dr. Quain was chairman, and said it would be the duty of that committee to consider what would be required for the next edition of

the work. He thought it would be dangerous to introduce changes too often, and he hoped that the Committee would not be in a hurry to bring out a new edition.

Dr. QUAIN said the Pharmacopœia Committee had not met for some time, as there had been nothing for it to do. With regard to the omissions referred to, it was impossible to please everyone; and what one person desired to be inserted, another was most anxious should be excluded. No doubt there had of late been a change of nomenclature, but that was no reason why *materia medica* and pharmaceutical chemistry should follow the fantasies of scientific chemistry. The subject would have to be considered by the Committee some time hence, but he saw no necessity for the passing of Mr. Macnamara's resolution.

Sir JAMES PAGET said it was a little singular to propose that a "future" edition of the Pharmacopœia should be up to the scientific standard of the "present" day.

Mr. MACNAMARA withdrew his resolution.

A communication was read from the Carmichael College of Medicine and Surgery, Dublin, in which it was stated that at the request of some of the students courses of evening lectures had been established. The letter stated that the action of the college "has been called in question by the Council of the Royal College of Surgeons in Ireland, and it has been stated that the General Medical Council would not sanction the course they have adopted. The directors have no wish to oppose the College of Surgeons in the matter. At the same time they cannot but feel that the laying down of any limits within which lectures must be given is an interference which is hardly justifiable, especially when the sole object of the directors was to afford the benefits of the lecture system to those students who, on their own showing, cannot otherwise obtain *bona-fide* certificates. It has been stated that men in business ought not to be encouraged to become medical students, and the authority of the General Medical Council, in recommending that four years should be spent exclusively in the study of medicine, has been urged in support of this view. In both statements the directors most fully concur; but they fail to see, as men in business are permitted to be medical students, that it is not a great deal better for them to have the opportunity of gaining such knowledge as the directors believe can only be obtained from lectures than that they should not. Under these circumstances the directors are anxious to know the opinion of the General Medical Council on the point; and it may be added they would only be too glad to retire from a position imposing so much personal inconvenience on their lecturers, should the Council consider the course they have taken undesirable." The Royal College of Surgeons in Ireland passed the following resolution on October 30th, 1879:—"That in the opinion of this Council the system about to be introduced in two of the Dublin schools of medicine (as stated in the public advertisements) of giving courses of lectures late in the evening, and at night, in addition to those given during the day, is objectionable, and should not be put in practice."

Dr. HAUGHTON moved, and Dr. BANKS seconded, "That in answer to the foregoing letter from the Directors of the Carmichael College of Medicine and Surgery (of date November 5th, 1879), the General Medical Council do not desire to express an opinion as to the hours of the day during which medical lectures should be delivered."

Dr. ROLLESTON moved as an amendment, "That this Council expresses its approval of the resolution arrived at by the Royal College of Surgeons on this subject."

Mr. SIMON opposed the amendment. He said the Council could not possibly introduce a new law, that lectures were not to be tolerated which were delivered at night. It was a matter in which they had no right to interfere.

The amendment was negatived, and the motion adopted.

The following communications in regard to certificates of attendance on lectures were read:—

(a) Resolution passed by the General Council on July 19th, 1879:—"That the Branch Council for Ireland have its attention drawn to a statement made by a member of this Council, to the effect that certificates of attendance have been issued in a Dublin school to students who have not given such attendance, and that the Branch Council be requested to inquire into this matter, and to report thereon to this Council at its next meeting." (b) Letter from the Irish Branch Council, referred to the General Council by the Executive Committee:—

35, Dawson-street, Dublin, March 11, 1880.

Sir,—The Branch Medical Council for Ireland have had before them

the resolution of the General Medical Council which was communicated to them in your letter of July 22nd last, viz.:—

"That the Branch Council for Ireland have its attention drawn to a statement made by a member of this Council to the effect that certificates of attendance have been issued in a Dublin School to students who have not given such attendance, and that the Branch Council be requested to inquire into this matter, and report thereon to this Council at its next meeting."

And having carefully considered the same, adopted the report, of which the enclosed is a copy.

Yours faithfully,

W. J. C. MILLER, Esq.

W. E. STEELE.

Dr. HAUGHTON said the resolution of which he had given notice was necessary for his own vindication, as he was the member of Council referred to. When the communication from the General Council was read to the Irish Branch Council they reported that they were not able to throw any light on the case, and a resolution was passed to address letters to the secretaries of the several schools and hospitals inquiring what precautions had been adopted to insure the *bona-fides* of certificates of attendance issued by them to their several students. After referring at some length to the answers received from the several schools and hospitals, and commenting on their unsatisfactory character, Dr. Haughton moved the following resolution:—"The General Medical Council are of opinion that no medical authority should receive a certificate of attendance upon lectures or hospitals, unless such certificate state the actual number of attendances made by the holder, and the total possible number of attendances."

Mr. TURNER seconded the motion.

Dr. ROLLESTON opposed the motion on the ground that the Council could only control the examinations and not the certificates. If their examinations were real and trustworthy it was unnecessary to take the number of precautions which the postulation of bodily attendance would involve.

Sir J. PAGET thought the Council would be drifting back if the chief thing they required for the medical education of the student was his bodily attendance at lectures. The Royal College of Surgeons of England had certainly outlived that. They no longer required that the precise number of lectures personally attended by the student should be set down. There were many things done in the schools now which they considered very far better than an absolute rigid numerical attendance at lectures. Students were carefully watched, and their certificate of attendance was on the responsibility of their teachers. They did not think it right to say a student should attend a certain percentage of lectures, but they did not sign certificates of attendance at all, though the man might have been there every day, unless he passed such an examination as induced them to believe that he had made good use of his time. If a student had attended every day, and had not passed his examination, they could stand the test of law to say whether they should sign his certificate or not. That was a far better system than the record of the number of attendances at lectures or demonstrations of any kind. He protested against the idea that because there were a certain number of dishonest persons in Dublin therefore all honest men everywhere else were to be placed under regulations which were grievously burdensome, and very mischievous.

Dr. HUMPHRY also opposed the motion, which, on being put to the Council, was negatived—5 voting for it, and 9 against.

MEDICAL LEGISLATION.

Mr. SIMON proposed the following motion, "That the Council beg leave to bring under the particular notice of Her Majesty's Government the position in which the question of legislation for the medical profession was left standing at the time when the late Government retired from office, and respectfully submit to Her Majesty's Government that, in the opinion of the Council, it is essential for those important public interests which are involved in the good ordering of the medical profession that Her Majesty's Government should at their earliest opportunity consider and determine the course which they will advise the Legislature to follow, with a view to terminate a period of indecision and unsettlement, which is most injurious to the progress of medical education; and that the President be requested to give effect to this resolution."

Dr. QUAIN seconded the motion.

Dr. ANDREW WOOD moved the previous question. At this period of the session, and considering that the Government had already told them that they were taking the matter into consideration, it was far better to leave the matter where it was.

Dr. PYLE seconded the amendment.

Mr. SIMON said he had thought the resolution would be passed without comment, but seeing that it was opposed it was necessary that he should speak to the point. As the Council had resolved to go into detailed business he felt it his duty to give his best attention and labour to every question brought before it; but he had felt most strongly that they were conducting business, in the present state of the great questions affecting their profession, at so serious a disadvantage that he should hardly use too strong an expression if he spoke of it as waste of time. Prospective regulations such as they were considering, or prospective recommendations, could hardly be made by them with any force. Except for a political accident, with which the Council had nothing to do, the Committee of the House of Commons would before now have made recommendations to the House on proposals affecting the whole work of the Council—proposals for a variety of changes in the working provisions of the Medical Act, and proposals not originating there, for a change in the constitution of the Council. He appealed to every gentleman who sat at that Council as the representative of a teaching and licensing authority whether that state of things had or had not acted most prejudicially to the medical profession? The College of Surgeons had been seriously obstructed in the consideration of reforms in the arrangements of that institution by the knowledge that these great questions were being Parliamentarily agitated; and that, he was persuaded, had been the case in every one of the medical institutions of the country. A discussion was also going on in Parliament on the constitution of the Council, and that question had been before the Select Committee. That Committee, appointed at the instance of Dr. Andrew Wood, had sat for two years, and its final report, by an accident, had not been made. Was it not the duty of the Council to ask to have an answer on the questions which had been put before the Select Committee, so as to provide a termination of this state of trouble and uncertainty? The Select Committee, if it had continued its sitting, would doubtless long before now have reported. It was unable to do so, and was obliged to send in a provisional report. Its evidence, however, was almost all collected, and it might be that Government would think the evidence given was enough to justify action thereupon. He urged, therefore, that the Council should beseech the Government to terminate the present state of uncertainty and suspense. The course taken by Dr. Wood was part of a consistent opposition which he had offered to a policy accepted by the majority of the Council. It was not, however, as an advocate of the system of conjoint boards that he brought forward this resolution. He was an advocate of that system, and hoped it would be adopted, and that the Council would stand to its colours in the matter; but his reason for bringing forward the present motion was because the Council was paralysed by the presence of uncertainty. ("No, no.") He said "Yes." There might be a pretence of business, but it could not be real business, and could not exercise its legitimate influence while questions about its constitution remained in suspense.

Dr. QUAIN said the reason which specially led him to second the resolution was because the Council remained under the gravest accusations made before Parliament, and it was their duty to ask the Government to continue its inquiries, and to remove those accusations from them. If they remained quiet under those grave charges it would be taken that they were admitting their guilt.

Mr. MACNAMARA supported the motion as being a more straightforward and courageous proceeding than moving what he might be excused for calling, he hoped the expression was not unparliamentary, a cowardly resolution such as the "previous question."

The PRESIDENT said he thought the expression was objectionable.

Mr. MACNAMARA said he would withdraw it, but might he say a resolution which was not characterised by much courage? Unquestionably the Council ought to say one thing or the other. There was no question about this fact that grave disapprobation was expressed in public upon the working of the Council, about its constitution, and the way in which examinations were conducted, and they ought to be in a position either to stand or fall by those accusations. The resolution proposed by Mr. Simon would give them an opportunity of justifying themselves, and would put an end to the present state of uncertainty. The Council would never have the influence it ought to have until an end was put to

this agitation, and he could not see in what other way it was to be done than by requesting the Government to proceed in the matter.

Dr. ROLLESTON said that the principle on which he could not vote for the motion was that, of all evils in Church and State, and everywhere else, Government interference seemed to be the very greatest. Pending legislation, he advised the Council to do the best it could, and to show that it was doing its duty. Now that the Scotch gentlemen had destroyed the conjoint scheme, for which he would never forgive them, let them try to do their duty by going round and visiting, which was the proper thing to do. Let them show, at all events, that they had vitality. As to the grave disapprobation outside, he did not care one farthing for it so long as he knew he was doing his duty.

Dr. PYLE said he did not think the motion was at all called for. No one was more anxious than himself that the Select Committee should be reappointed, because many things had been stated in that Committee with regard to the University of Durham which were incorrect, and as to which they were to have had an opportunity of reply. It would be better, however, for the Council to leave the matter in the hands of Government, and to give no expression of opinion there.

Dr. HAUGHTON supported the motion on the ground that though it was all very well to speak of being independent of the Government, there were things which the Council could not do without the help of an Act of Parliament. There was a glaring defect in the legislation of 1858, and if they expressed an opinion to the Government that steps should be taken to reform this glaring deficiency, and to require that everyone should possess a knowledge of all three branches of the profession before registration, they would only have done their duty.

The PRESIDENT said the statement made by Mr. Mundella on the 27th of May was that during the coming session the whole question would be considered by the Government.

Dr. HUMPHRY said he should vote against Mr. Simon's motion, and for this reason, that he would rather bear the ills he had than fly to those he knew not of. It was not a question of asking for any particular legislation or of giving any opinion to the Government with regard to any particular subject, but it was a question broadly and plainly of asking for legislation, and he was not prepared to do that. It was not wise for the Council to be dabbling in this matter of legislation unless it was called upon; they had had too much of it already. Their time had already been wasted, and their attention diverted from their real work. He should be very glad if there was no legislation at all, and the Council was left to go on armed with the powers it had in its own proper way. As to the Council carrying weight, it would carry weight if it did its duty, and its resolutions were wise and just. He regretted that the conjoint scheme was not carried further, and he laid it to the charge of England that it was not done. England had been to blame not to do that which it thought right in spite of legislation, in spite of Scotland, and in spite of Ireland. He felt that if England would do its duty Scotland would do likewise, and a good work would be carried on.

Mr. SIMON, in replying, said it was preposterous to pretend now to a horror of Government interference, it having been at the instance of the Council that the Government had acted in the matter. He (Mr. Simon) was not asking for legislation, but for a settlement. It might be that on inquiry the Government would not think it desirable to legislate. All that he asked for was for some decision which would put an end to their present indeterminate state. But it did not depend on the Council whether Parliament would be asked to legislate; private Bills would be introduced next session if the Council took no action, and they would then be thrown into a new unsettlement.

The amendment was then put, and carried by 12 votes against 7.

The following notice of motion having been placed on the programme:—"To submit to the General Council a communication from the Apothecaries' Society of London, relative to certain evidence which has been given before the House of Commons' Select Committee on the Medical Act (1858) Amendment Bill,"

Mr. BRADFORD moved that the communication be read.

Dr. PYLE seconded the motion.

Dr. PITMAN asked whether there was not a discretion in the President to withhold such information as he considered did not relate to the matter of business of the Council. The

letter referred to some evidence that had been given before the Select Committee against the Society of Apothecaries, and was not in any way connected with the Council. He therefore moved as an amendment that, "Inasmuch as the evidence given before the Select Committee of the House of Commons in 1879, on the Medical Act (1858) Amendment Bill, was not given by any one under the authority of, or on behalf of, the General Medical Council, it would be improper for the Council to receive any statement in correction of that evidence."

Dr. ROLLESTON seconded the amendment.

The PRESIDENT said that, acting on his discretion, he had not put the letter on the programme, because it entered into the debateable question of the truth or non-truth of charges brought not at that Board, but before the House of Commons. Of course the document was in the registrar's office, and could be seen at any moment.

Sir JAMES PAGET said from what he knew of the letter it would be most indiscreet to read it; it would evoke at once answers from at least five persons.

The PRESIDENT said he should certainly suggest if the letter was read that strangers should withdraw.

Mr. BRADFORD said as it seemed to be the wish of the Council he would withdraw his motion.

On the motion of Dr. ANDREW WOOD, seconded by Sir JAMES PAGET, it was resolved, "That the Council resume the visitation of examinations, and carry it on systematically from year to year," and also, on the motion of Dr. HUMPHRY, seconded by Dr. ROLLESTON, "That it be a direction to the Executive Committee to instruct visitors to inquire into the causes of the rejections that appear in the annual returns."

The thanks, &c., of the Council having been accorded by acclamation to the President for his efficient services during the present session of the Council, and also to Dr. Andrew Wood, the Chairman of the Business Committee, the proceedings of the session terminated.

Analytical Records.

CONFECTION OF FRESH BAEI FRUIT.

(SQUIRE, OXFORD-STREET.)

THE fruit of the Bael (*Egle Marmelos*), which enjoys some reputation in India for the treatment of dysentery, has lately been used to some extent in England, and we have heard of more than one case where it has apparently been beneficial. Messrs. Squire's preparation is all that can be wished, as it is bright and agreeable in appearance and pleasant in taste.

HYPOPHOSPHINE.

(GALE & Co., BOUVERIE-STREET, LONDON.)

Cod-liver oil in emulsion, with the hypophosphites of iron, lime, soda, and magnesia. The taste is nauseous, but might, we think, be disguised.

MACKAY'S QUINQUININE.

(MACKAY, MACKAY, & Co., BOUVERIE-STREET.)

Contains the alkaloids of the bark in a colourless and easily soluble state. It is of course much cheaper than pure quinine, and is in some cases equally efficacious. There are, indeed, some patients who derive more benefit from Peruvian bark than from quinine; for such patients the use of quinquinine is obvious.

VAN ABBOTT'S PREPARATIONS FOR DIABETICS, ETC.

(VAN ABBOTT, PRINCE'S-STREET, CAVENDISH-SQUARE.)

1. *Real Turtle, Mock Turtle, and Ox-tail Soups*. — Free from starch, and as free as possible from fat and seasoning; excellent in quality and flavour.

2. *Extract of Vegetables, for flavouring Extract of Meat, Soups, Gravies, Hashes, &c.* — A wonderfully well-flavoured and powerful essence. A few drops give quite an appetising taste to beef-tea, broth, &c.

3. *Chocolate with Liebig's Extractum Carnis*. — A French preparation, sold in cakes, sticks, and croquets. It is made

without sugar, and will be thought unpleasant in taste by many. Of course it is highly nutritious and stimulating.

ALLEN AND HANBURY'S MALTED FARINACEOUS FOOD.

(ALLEN & HANBURY, PLOUGH-COURT.)

This is introduced as an improved form of Liebig's well-known food. It is excellent in quality and flavour, is perfectly free from grit, can be made up in a few minutes, and requires no straining. Children will be sure to thrive upon it.

New Invention.

A STEAM ANTISEPTIC SPRAY-PRODUCER WITH INFLUX-PUMP.

SOME months ago we were able to speak in favourable terms of a steam spray-producer manufactured by Messrs. Matthews Brothers, of 27, Carey-street, W.C. (See THE LANCET, Oct. 25th, 1879, p. 629.) These makers have recently still further improved their apparatus by attaching to the boiler a powerful influx-pump for the purpose of supplying water to the boiler. The advantages of this arrangement are obvious. The spray may be started within two minutes, and then kept up for an indefinite time. At first, a small quantity of water, not more than a few ounces, may be pumped into the boiler, and a good jet of spray will be obtained within two minutes. When the steam has once been raised, more water may be injected at short intervals by means of the pump, without stopping the spray. Both the spirit in the lamp and the water in the boiler may at any time be replenished without interfering in any degree with the working of the apparatus; so that, when once set a-going, very little attention is needed to keep it continuously in action for any length of time, from a few minutes to many hours, days, or even weeks, if required. The principle of the apparatus is extremely simple, and there are no dangers or practical difficulties in carrying it out.

In some experiments we made, using cold water to begin with, we obtained a large jet under 50 lb. pressure in a minute and a half; and by gradually injecting fresh water by means of the pump, the spray was kept up continuously for forty minutes, and at the end of that time the boiler contained sufficient water for a continuous spray, under 50 lb. pressure, for one hour, without further attention. This arrangement is a most satisfactory improvement in the spray-producer, and has long been a desideratum.

THE LANCET.

LONDON: SATURDAY, JULY 24, 1880.

THERE is no serious cause to regret that the items of information to be required by the Census enumerator on the 3rd of April next are essentially the same as those obtained at the last Census on the corresponding day of 1871. In order to justify an enlargement of the scope of the inquiries contained in the Census schedule, it should be conclusively proved not only that the new information would possess undoubted value, but that there would be no general objection to supply it. We have no hesitation in saying that, as regards a religious Census, an industrial Census, and a Census of health and disease, the returns would be of doubtful value, while there would be much risk that the irritation and prejudice excited by these new questionings would affect the accuracy of replies to inquiries to which the public has become accustomed at recent Censuses. Under these circumstances, we see little cause for regret that the Census schedule under the Act for 1881, now before Parliament, is essentially the same as that authorised by the Act for the last Census. *The Times* of Tuesday last contained an example of the hundred and odd purposes which many persons would endeavour to make the decennial Census enumeration serve. It was there proposed that the relationship (if any) of the parents of all persons enumerated should be ascertained and recorded. We do not pretend to say that this and a host of other items of wished-for information would be valueless; but knowing the machinery by which the Census of this populous country has to be taken, the ignorance of a very large proportion of those to be enumerated, and the important fact that the whole of this information has to be collected on a single day, we hold that it would be mischievous to complicate the inquiry. There may be good grounds for objecting to the length of time (nearly three years) which elapsed between the last Census enumeration in 1871, and the issue of the final report. It appears, however, to be lost sight of that a detailed preliminary report of the population numbers is always issued within four months of the Census, and that the fully revised and elaborated tables are issued from time to time as they are completed. That the date of this completion might be anticipated after the approaching Census there is little reason to doubt, but this is not, we fear, to be effected by the proposals of Mr. EDWIN CHADWICK, C.B., which are now being supported in the House of Lords by Earl FORTESCUE. The proposal to delegate the preparation of the Census tables to about 600 local solicitors and their clerks in different parts of England and Wales, who may happen at the time to be clerks to the Guardians and Superintendent Registrars, is impracticable. The registration district, it is true, is in a certain sense the registration unit, but for practical purposes it is only so nominally. The city of Bristol, for instance, is situated in three registration districts (Bristol, Barton Regis, and Bedminster), and, therefore, under Mr. CHADWICK'S

system, the statistics of that city would be prepared and tabulated in three parts, and under the quasi-superintendence of three different local officers. It is to be hoped that this suggestion for the local preparation of the Census tables may be withdrawn. At the same time it should not for a moment be lost sight of that the value of the Census information depends in great measure upon the promptness with which it can be rendered available. Above all, however, is the absolute necessity for uniformity in the preparation of the various tables, which could not be secured if this process were superintended by more than 600 local officers, whose interest in registration matters is, in the large proportion of cases, of the very slenderest description.

THE discovery, some years ago, by M. GRÉHANT, that carbonic oxide is one of the products of the combustion of tobacco, has led to the suggestion that the deleterious effects of tobacco-smoking are due to this substance. The suggestion seems improbable enough when we consider what powerful poisons are liberated at the same time, but the theory has seemed to M. GUSTAVE LE BON worthy of a careful experimental investigation, the facts of which are of some interest. The quantity of carbonic oxide formed was found to amount to about 800 cubic centimetres for each ten grammes of tobacco burned. One per cent. of carbonic oxide in the air breathed will cause death in twenty minutes, and its action is effected, as CLAUDE BERNARD showed, by combining with the hæmoglobin. What dose of carbonic oxide, however, without being fatal, will cause dangerous accidents? M. GRÉHANT formerly killed dogs by compelling them to breathe air which had passed through a pipe containing some grammes of tobacco in combustion, and ascertained by spectroscopic examination the quantity of carbonic acid in the blood. These observations, repeated by M. LE BON, yielded the same results as M. GRÉHANT had obtained. The air, passing through four grammes of tobacco in combustion, caused death in a quarter of an hour; clots were found in the heart, and the blood contained traces of carbonic oxide. Evidently, however, such experiments are of little value, because the air breathed is deprived of its oxygen, and the proportion of nicotin, &c., is so great that the effects cannot reasonably be ascribed to the carbonic acid. Some experiments were then made by first removing the nicotin from tobacco by the action of boiling ether and ammonia, many times repeated, and then adding to the air which passes through the burning tobacco a sufficient quantity of oxygen to replace that lost in combustion. Nevertheless, in the experiment thus performed, in fourteen minutes the dog was dead, and the spectroscopic examination of the blood showed the presence of carbonic oxide. This result was to be anticipated, for the amount of carbonic oxide produced by the combustion of the tobacco employed amounted to a fatal proportion of the air respired. But this result is scarcely applicable to the conditions met with in ordinary tobacco-smoking. To ascertain the effect of the carbonic oxide in the latter, it was necessary first to determine the minimum proportion which is deleterious, and then the quantity actually present in a smoker's most limited atmosphere. On the former point physiological researches give little information. To

decide it, M. LE BON shut himself in one of the extremely small kitchens met with in some of the Paris lodging-houses, and lighted two stoves (we presume charcoal). In this room, in spite of a chimney, it was ordinarily necessary, for safety, to have the door open. With the closed door, he remained in it until violent headache and nausea became unbearable. Then, before opening the door, he filled with air, by means of bellows, an india-rubber ball holding twenty-five litres. This was not accomplished without difficulty, for his condition had become most unpleasant. Analysis showed that the air contained only one part of carbonic oxide for 3000 parts of air. In order to produce this proportion of carbonic oxide, it would be necessary to burn 4 grammes of tobacco per cubic metre of air. In a small room—say one of a capacity of 30 cubic metres—it would be necessary to burn 125 grammes of tobacco to produce this quantity of carbonic oxide—an amount of tobacco which would be represented by 50 pipes, 25 cigars, and 250 average cigarettes. The renewal of the air by the door and windows, even if these were closed, would render the amount of tobacco needed much larger; but without considering this, it is evident that the quantity of tobacco could not be burned by the small number of persons who could be accommodated in such a room. In a compartment of a railway carriage, however, or in a closed cab, a number of smokers might be confined in a much smaller atmosphere. The renewal of the air by the imperfectly-fitting doors and windows would be, however, much greater than in the other case. The effect could only be determined by an actual experiment. Accordingly, M. LE BON and a friend entered a single-seated cab, which, when their own bulk was deducted, contained about thirty cubic feet of air. The windows of the cab were closed, and for three-quarters of an hour M. LE BON and his friend drove about, and smoked during the time seven grammes and a half (a quarter of an ounce) of tobacco. The temperature of the interior of the cab was 55° F. at the commencement of the experiment, and 71° F. at the end. As some discomfort was experienced, the observation was stopped, an india-rubber bag, holding twenty-five litres, being filled with the air. According to the quantity of tobacco burned, the air should have contained 500 cubic centimetres of carbonic oxide in each cubic metre of air; the quantity was found on analysis, however, to amount to scarcely 100 cubic centimetres—too small a quantity to produce serious inconvenience. It is thus evident that in a carriage, in spite of closed windows, there is such an extensive change of air, that the greater part of the carbonic oxide escapes. It is also certain that, even if it did not escape, long before it reached a deleterious amount the effects of the other poisons, nicotin, &c., produced by tobacco-smoking, would be much more obtrusive.

“By the permission of the Council this motion was withdrawn.” This sentence is the only indication on the smooth surface of the Minutes of a sharp passage of arms between Mr. SIMON and Dr. ANDREW WOOD, two members of the Council whom it is difficult to respect too much, but who sometimes have strangely different views of its duties and its dignity. The withdrawal of “this motion” almost as soon as it was mooted, signified recession on the part of the Council from high ground which it has taken up on several

former occasions. There are few subjects on which the Council has been more agreed than on the following proposition, which is taken from its Recommendations:—“That it is desirable that the examination in general education be left to the universities and such other bodies engaged in general education as may from time to time be approved by this Council.” Mr. SIMON, on the “penultimate” day of the late session, probably thinking that there was little to show for a week’s work, that the difference between the recommendations agreed to this year and those agreed to in former years was very much the difference between *tweedledum* and *tweedledee*, and that something in the nature of decision and progress should be shown, proposed to omit from the list of bodies giving testimonials of efficiency in general education the names of the Medical bodies which continue to grant such testimonials. In doing so he was evidently merely endeavouring to put into force the oft-repeated opinion of the Council. But he little remembered the difference between a general expression of opinion by the Council and the proposal to enforce it, and he was soon fain to retire from the fray. The great principle of requiring the national educational bodies to examine in general education, leaving the medical bodies free to complete the system of medical examinations, was not even reaffirmed. “With the permission of the Council the motion was withdrawn.”

Mr. SIMON was the proposer of two other resolutions, one carried and the other rejected, which call for some notice at our hands. As has often been the case in previous sessions, these resolutions were put far back on the programme, and had to be disposed of with more haste than was quite fit. The motion which Mr. SIMON carried was as follows:—“That, in the opinion of the Council, it is desirable that intending candidates for the medical profession should, before they enter on the purely medical curriculum, have been instructed and examined in the rudiments of natural science, physical, chemical, and biological, and that, in proportion as this can be done, the present medical curriculum and present professional examinations should be lightened of all such matters.” In explaining his views on this motion, Mr. SIMON said that this examination should be after preliminary general examination and before commencing the distinctively medical curriculum, or, at the latest, before the end of the first year, and should embrace an elementary knowledge of mechanics, solids and fluids, of heat, light, and electricity, of general chemistry, and of the constitution of plants and animals. The examination here indicated by Mr. SIMON, it will be seen, corresponds in nature very much with the Preliminary Scientific Examination of the London University, which comprises the subjects of Inorganic Chemistry, Experimental Physics, Botany and Vegetable Physiology, and Zoology, and is not to be passed before the completion of the seventeenth year. Notwithstanding the promise included in Mr. SIMON’S resolution, that in proportion as these subjects can be passed by intending candidates for the medical profession, the present medical curriculum and the present professional examinations shall be lightened of all such matters, it looks very like the imposition of a new examination, which may prove a very hindering one to intending candidates. If this is the object of it, or if Mr. SIMON agrees with Sir WILLIAM GULL that the great object of all medical examinations is to

exclude 33 per cent. of those who try to pass them, then it may be all right; but we venture to say that in the present state of general and professional education the Council would have done better to have left the institution of a Preliminary Scientific Examination alone, or to have been content with adding Zoology to the list of optional subjects. There can be no doubt as to the abstract desirableness of such an examination as Mr. SIMON foreshadows, carried even to the extent of the Preliminary Scientific Examination of the University of London. But until the Council has been much more successful than it has been in improving the general preliminary education of the candidates for the profession, it is premature to speak of imposing a new examination. It was the general opinion that if such an examination is to be carried out, it must lead to the postponement of the age at which a diploma can be granted by several years, and it is questionable whether any such change would be looked on favourably by those who have to see the ranks of the profession filled. We need not, however, be much alarmed. The Council has, in its own happy way, only referred the subject to a committee. This will have a pleasant correspondence with the licensing bodies on the subject, and report at its next meeting. Probably on the last or "penultimate" day of the session a motion may be brought forward, and possibly, by the permission of the Council, the motion will be withdrawn.

Mr. SIMON failed to carry a motion which should have had the hearty support of every member of the Council, but which was rejected by the following majority of twelve:—Sir JAMES PAGET, Mr. BRADFORD, Dr. ROLLESTON, Dr. HUMPHRY, Dr. PYLE, Dr. HALDANE, Dr. ANDREW WOOD, Dr. SCOTT ORR, Mr. TURNER, Dr. AQUILLA SMITH, Dr. LEET, and Dr. BANKS. The motion in question was one urging on Her Majesty's Government at their earliest opportunity to consider and determine the course which they will advise the Legislature to follow, with a view to terminate a period of indecision and unsettlement, which is most injurious to the progress of medical education. Mr. SIMON's motion was seconded by Dr. QUAIN, and very ably supported by Mr. MACNAMARA, the representative of the Irish College of Surgeons. Mr. SIMON never spoke with more power or dignity, and he is not given to speak without displaying both of these qualities. There can be little doubt that the Government will perceive the force of his representations and those of Dr. QUAIN, who well observed that this question was sure to be raised in Parliament, even if the Government failed to raise it. Some of the speakers did not hide their feeling of hope that the Government would find itself too busy to take notice of the subject. And this is probably the feeling of many who did not express it. They must have strange notions of what a Government owes to such a profession as ours, and to the public who are deeply interested in its efficiency. And we cannot understand how, with respect merely to the influence and dignity of the Council, they can be content to remain in their present position in Parliament—accused and not acquitted. There are some things which one Parliament owes to another, and amongst these is the amendment of the Medical Acts, from which the Government is not likely to be deterred by the self-complacency of the Medical Council.

Annotations.

"Ne quid nimis."

NAVAL MEDICAL DEPARTMENT.

EIGHT months have now elapsed since the War Office issued its warrant for the improvement of the position of the army medical officers. It has been so satisfactory in its results that there is every probability of the staff being brought up to its normal standard at the approaching competitive examination, and thus the nomination scheme will be staved off.

The navy awaits the issue of a corresponding document, of which, however, no shadow is apparent. Possibly the Admiralty may contemplate keeping the service in its present bare working order with a margin of about thirty-five officers on half-pay, and filling up the vacancies that occur in it with rejected candidates for the army. We would rather see this important branch of our profession maintaining its ancient prestige with a sprinkling of F.R.S.'s in its ranks; and, therefore, we shall hope to be able to hail, with a welcome, a liberal and comprehensive Warrant placing the naval service on its old relative superiority to the army in regard to full pay, retired pay, and good-service pensions, in respect of which the balance has been shifted by the late Army Warrant. Much is wanting on these grounds, if comparison be made of the chances of promotion to administrative ranks in the sister services, by which alone the higher scales of retirement can be reached.

THE LIABILITIES OF FOREIGN EMPLOYERS.

THE reports on the laws in force in France and Germany with regard to the legal liability of employers from a short but interesting document, prepared in order to facilitate legislation on this subject in England. We cannot, however, attempt to discuss the economical and social problems involved in the measure now before Parliament and in the laws actually extant on the Continent. What we would insist upon is the necessity of adopting more ample precautions in England so that efficient help may be forthcoming in case of accident. In France, so far back as 1604, a special degree of the Conseil du Roi had ordered that one-thirteenth part of the net proceeds of each mine should be applicable to the maintenance of one or two priests and of a surgeon, and to the purchase of healing appliances in aid of workmen who had met with accidents. In France the principle of civil liability of employers has no limit, and though special provisions have been laid down in the case of certain industries, the general law suffices to protect workmen, to insure compensation for accidents, and a pension for the wife or children in case of death. This rigour has led to the adoption of precautions unknown in this country. Thus the railway companies, responsible for the lives not only of the passengers, but of their workpeople, provide each train with a large medical chest, with splinters, bandages, and even the necessary implements for amputations, &c. Considering that railway accidents are far more frequent in England than in France, we regret that this detail could not be introduced in the report before us. It is a useful hint.

In Germany we find that the employer is, in case of bodily injury, liable to the payment of the medical expenses and of the losses which may have accrued to the injured party through his inability to earn. This regulation should result in securing efficient medical aid, which would not always be the case if the workmen were left to their own resources and devices. Indeed, there remains much to be done abroad and still more in England for the prevention of accidents and to insure better and more prompt assistance when they do occur. By increasing the liability of employers a greater

amount of intelligence will be brought to bear on the methods of prevention and of cure. Thus accidents will not be so frequent or so fatal, and that, after all, is the most important consideration.

AMATEUR STARVATION.

THERE seems to be no doubt that Dr. Tanner, of Minnesota, is honestly bent on starving himself, or going as near to doing so as circumstances permit. He has already accomplished twenty-four days of fasting, out of the forty which he has planned to complete, and as yet gives no evidence of danger. Meanwhile, the daily papers are filled with the fame of his exploits, and all the details of his irritability of temper, &c., are recorded with repulsive minuteness. It would ill become a paper with any reputation for science to take too much notice of this latest development of sensationalism. As a scientific experiment Dr. Tanner's fast ranks but little higher than the prolonged walks, swimming contests, &c., which have of late been so common. Its sole object, so far as we can learn, is to ascertain, not whether a man can live forty days without food, which has already been proved in undoubted cases, but whether Dr. Tanner can live, as he says he can, forty days without food. On the other hand, it has also been proved that death may occur at a much earlier period; and the main question is, whether Dr. Tanner will be allowed to starve beyond the point of recovery. If, as is possible, he survive the forty days, he will be an interesting case for treatment, and may run further chances of death before he can resume his normal condition. It is difficult to understand what will be gained by this experiment. No doubt it would have been of some physiological interest if careful investigation had been made as to the amount and nature of excreta, the temperature, respiration, &c.; but beyond some very crude observations on weight, pulse, and temperature, nothing of the kind seems to have been done. Indeed, *pace* the anti-vivisectionists, the same thing has been already much better done on certain of the lower animals. Experiment has shown that animals live much longer when supplied with water than without, and Dr. Tanner has already found it necessary to stay the cravings of thirst, and now takes water freely—so far departing from his earlier procedure, when he only rinsed his mouth with a measured quantity, which was again measured after having been used.

In carrying out his proposed experiment, Dr. Tanner would appear to have found plenty of people to aid and abet him, and encourage him to persevere. There is no reason to believe that he proposes to make money by it, though it would seem that he might easily do so. There have been suspicions of surreptitious supply of food, but these are now believed to be groundless. He appears to have been received with open arms by the "United States College of Physicians," whose offices are above, and their dissecting-room (*absit omen*) below the faster's reception-room. Here the faster performs his abstinence, his ablutions, and his rest, in the presence of an admiring public, and is constantly watched by physicians of the "regular," "irregular," and "eclectic" schools, in order that by no chance or design any morsel of food may reach his lips. Even his finger-nails are examined, lest he should have concealed morphia beneath them, and thus assuage the pangs of hunger; everything, in fact, is done to prevent any possibility of deception. How far this is morally justifiable is an open question. Perhaps if the faster become delirious, have convulsions, or any other sign of impending dissolution, humanity may gain the day, and attempts be made to restore him; but it is noteworthy that if this is done before the forty days the experiment will be spoiled, and it may be worth while to wait to make sure that a fatal termination is approaching. Or again, if a forty days' fast is completed, would it not be

worth while to try exactly how long he can live beyond that time without food? for it would be a pity to spoil so good an experiment, which has gone so far, without making quite sure of how much longer it may be continued. An arbitrary limit of forty days is unscientific, as a case is on record extending to fifty-eight days. An additional argument is to be found in the fact that the experiment will not be complete without a post-mortem examination. Apart from these considerations, we see little in the experiment to excite interest or approbation; its final issue will be of statistical value, and its complete record one of the most unpleasing of sensational tales. So far as can be guessed from the reports of American newspapers—not always a very trustworthy source of information—none of the more respectable or scientific of New York physicians or physiologists have taken any part in the experiment, if such it can be called; and we trust that they will discountenance it in the interest alike of science and humanity.

THE "NEWCASTLE CHRONICLE" ON MEDICAL QUALIFICATIONS.

OUR able contemporary, commenting on the recent exposures of the system of bogus diplomas, has some very important remarks on the Medical Acts and their administration, "and the successive amendments to which these Acts have been subjected with a view to greater efficiency." It is eminently desirable, our contemporary says, that those to whose care the national health is in a large measure entrusted should be strictly competent for their duties, and to this end candidates are required to pass rigorous examinations. So far true enough, but only so far, as our contemporary's correspondent "Justitia" has well said. An investigation of this subject yet further will reveal the fact that the most important amendments in the Medical Acts are unaccomplished, and waiting to be dealt with by the new Ministry. These amendments aim at reducing the harassing and injurious number of competing examining bodies, the improvement of medical education and medical examinations, and the making more easy to the public the distinction between qualified medical men and unqualified. If the *Newcastle Chronicle* will help us in procuring such amendments it will be completing "one of the most beneficent features of modern legislation."

THE BELL NUISANCE.

COMPLAININGS come from the City of what may be called the bell nuisance. This is a matter in which the sick and the sensitive have a keen interest. To healthy persons generally it may not be a source of serious annoyance, though many would, if they confessed the truth, be found to agree with Mephistopheles, in the play of "Faust"—so admirably rendered by the late Mr. Phelps,—when, stopping his ears, he exclaims, "What execrable taste some people have!" No inconsiderable proportion of the community, however, are not in such robust health as to be able to endure the clanging of church bells in a city, where the sound reverberates along the roofs of lofty houses and around chimney-stacks, reaching the ground between high and bare walls, like the noise of keys rattling in a box. In the rural districts, where the sound is softened and subdued by trees, and there are no long and confined streets to intensify the clangour, the result is different. The suffering caused to the sick by these bells is very great, and to many persons who are in health but have the misfortune to be compelled to work with "what they are pleased to call their" brains, the effect is almost maddening. It is much to be regretted that something cannot be done to mitigate this nuisance, for such it really is. Prejudice will, of course, defend the ringing and tolling of church bells in cities as elsewhere,

although the conditions are altogether different; but if the clergy are considerate as well as wise, *they* will consent to minimise instead of augmenting the stress of the evil, else there may come a time when the maledictions heaped on the practice of bell-ringing and tolling *sotto voce* will be loud and deep as the clanging that now rouses the evil spirits instead of laying them.

THE ARCIFORM FIBRES OF THE MEDULLA OBLONGATA.

M. LUYLS has made an interesting communication to the Société de Biologie on the subject of the connexions of the arciform fibres of the medulla oblongata. He maintains that they are nothing more than the terminations of the inferior cerebellar peduncles. After these have reached the lateral parts of the medulla, the fibres pass obliquely into this region, and increase its size by passing between the ascending fasciculi from the spinal cord. Some of the fibres, however, pass into the interior of the medulla, and these are the concentric fibres which form so conspicuous a feature in all transverse sections of the medulla. That part of the fibres which apparently remains on the external surface of the medulla, and extends on the restiform bodies and anterior pyramids, presents great variations in direction and terminal distribution. Some of the fibres surround the olivary bodies, and penetrate the median raphe; while others have a serpentine direction towards the pons. The conspicuous fact regarding these fibres is that, whatever be their course, all seem to decussate at the middle line, and this decussation in fact constitutes the median raphe, the significance of which has not been accurately estimated. The ultimate destination of these fibres is still uncertain. M. Luys thinks it probable that, after decussating, they enter one of the deposits of grey matter which are seen close to the raphe, and which are composed of large cells, with interlacing processes. Others probably pass to the network of cells of the olivary bodies on the side opposite to that on which they entered the medulla from the cerebellum. In support of these views, he showed sections from a case of congenital atrophy of one lobe of the cerebellum. The inferior cerebellar peduncle on that side was completely atrophied, and so also was the olivary body on the opposite side, which contrasted strikingly with the full development of the olivary body on the same side. This important observation speaks strongly for the view advanced by M. Luys, that there is an intimate connexion between the olivary bodies and the cerebellar fibres.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE Council of this Fund is summoned for Monday next to sanction the awards recommended by the Distribution Committee. The Council will have the pleasant duty of awarding to all the institutions on their list on a higher basis than last year. We cannot but feel some satisfaction that it will have over a thousand pounds more to distribute than in the previous year. We proposed to the clergy the imitation of a provincial town, and they have made a noble beginning of such an imitation by pleading most earnestly and with great success for the Fund. It is to be hoped they will attend in good numbers on Monday and show as much interest in the distribution of the Fund as they have shown in its collection.

THE WELBECK CASES OF POISONING.

WE understand that Dr. Ballard is still pursuing his inquiry into the curious series of cases of apparent poisoning—some fatal—which occurred at the Welbeck sale. It was assumed at the inquiry of the jury that the consumption of certain sandwiches, in which both beef and ham were used,

was the immediate cause of the sickness produced; and it was suggested that the poisonous quality of the meat had been developed in consequence of exposure to sewer air in a somewhat concentrated form in a particular larder. The case throughout proves to be unusually complicated, and even the number of cases of poisoning have not yet been ascertained. For it appears that persons coming from long distances to the sale have suffered from sickness by partaking of food, or exposure to some unwholesome cause, there, and information has still to be sought out before the whole range of mischief can be ascertained, and the cause determined.

H.R.H. THE PRINCESS LOUISE (MARCHIONESS OF LORNE).

THE *Toronto Globe* has the following:—"Her Royal Highness has been suffering ever since her departure hence for Metapedia, on a salmon-fishing expedition, from nervousness and sleeplessness. The visit to Metapedia was shortened by about a fortnight on account of the indisposition of the Princess, which it is believed by the physicians to be the result of the sleigh accident last winter. No local affection is, however, feared as the result of that accident, but the entire nervous system has been upset. Her Royal Highness has been advised by her medical attendants to visit a German Spa, after which she will spend some time in England before returning to Canada. There is nothing fresh known about Prince Leopold's state of health. His Royal Highness and his sister, the Princess Louise, will sail together with their respective suites on board the Allan Line Royal Mail steamer *Polynesian*, from Quebec, on the 31st instant. Secrecy has been maintained up to the present concerning the indisposition of the Princess, and it is only to be accounted for on the supposition that it was feared exaggerated reports might reach Queen Victoria through the newspapers."

POST-MORTEM EXAMINATIONS.

WE thought the silly old prejudice against "post-mortem examinations" had died out. The example set by the educated classes has not, it seems, yet wholly dispelled the dense ignorance of the lower orders. A few days ago at Gloucester an action was brought by a labouring man against the house-surgeon of the county infirmary to recover the sum of £2 for injuries inflicted on his "feelings" by an examination of the body of his wife, who had died of an obscure malady. It is time this very foolish prejudice became extinct. The ministers of religion, who sometimes act with strange folly in the matter, should make it their business to explain the necessity for a verification of the medical opinion formed during life. Pathological research is the only mode of investigation in the interests of the living. The position assumed by the clergy, by boards of guardians, and by magistrates in respect to this matter is not satisfactory. They do not appear to recognise the difference between an inquiry with pathological purposes and a mere anatomical study. Surely persons of average intelligence cannot be so obtuse as to confound things which not only differ but, in practice, conflict.

"LEGALISED QUACKERY" AND LOW CHARGES.

The *Hastings and St. Leonards Times* comments on an article headed "Legalised Quackery" contained in the *Chemists' Journal*. The persons attacked are medical men who profess to give medicines and advice for sixpence at a so-called "Dispensary." The *Chemists' Journal* says the stock in trade of such a dispensary consists simply of Epsom salts, chalk, carbonate of soda, castor oil, methylated spirits, and the like, with burnt sugar and other colouring matter. We have little respect for the system of giving advice and

medicines for sixpence. It is a delusion to the patient and a snare to the practitioner. The practitioner goes through the form of a professional duty under altogether bad conditions. The money will not cover the cost of proper drugs, and the scanty time and attention that can be given to such forms of practice and for such considerations must be demoralising. If the patients cannot pay more, they are veritable paupers, and medicine acquires no benevolent or dignified character in pretending to treat them on private and independent terms.

CRUSTACEAN PERCEPTION OF LIGHT.

THE beautiful experiments of Dewar, in which he ascertained the action of light of different colours upon the retina of various vertebrate animals, by investigating the force of the electrical current which was generated in the retina and optic nerve by the impinging rays, have been repeated upon the arthropoda by M. J. Chatin. The observations were made chiefly upon beetles and crayfish. The gasteropoda were found inconvenient for the investigation. The maximum deviation of the electro-motor needle was constantly found to be produced by the yellow rays, the next with the green, and the minimum was usually obtained with red light. Hence Dewar's law is as true for the arthropoda as for the vertebrata, that "the maximum effect is produced by those parts of the spectrum which appear to us to be the most luminous—the yellow and the green."

CHELSEA HOSPITAL FOR WOMEN.

ON Friday last, July 16th, H.R.H. the Princess of Wales, accompanied by H.R.H. the Prince of Wales and two of their children, laid the foundation-stone of the new building about to be erected for the Chelsea Hospital for Women. The present hospital, which was opened in 1871, is in the King's-road, Chelsea, and has accommodation for eight in-patients only; but the committee was soon compelled to consider the necessity of having a larger and more suitable building, as the demand for beds was constantly in great excess of the supply. In 1878 a site was purchased in the Fulham-road, nearly opposite the Brompton Hospital for Consumption, but the building was not commenced until sufficient funds were in hand to prevent financial embarrassment. Up to the present time over £8000 has been received or promised towards the new building, which is to provide accommodation for nearly sixty in-patients, as well as a commodious out-patient department. The plans have been drawn up by Mr. F. T. Smith, of Parliament-street, under the direction of Mr. Wilkins, a supporter of the institution. The building will be forthwith proceeded with.

THE STRUCTURE OF SPERMATOOZOA.

IN the current number of the *Quarterly Journal of Microscopical Science* is a short paper by Dr. Heneage Gibbes, in which he states that he has found the spiral filament, discovered by him in the spermatozoa of several species of animals, as the rat, mouse, axolotl, pigeon, fowl, snail, and leech. In the examination of different specimens of human spermatozoa, he has noticed a variation in the length of the tails, and in one specimen he found a number of heads with no corresponding tails. He throws out the suggestion that these variations may have some important bearing. It is quite possible that tailless spermatozoa may not be able to fertilise the ovum, while the greater the length of the tail the greater their locomotion and fertilising power may be. Dr. O. S. Jensen, of Bergen, has found the spiral filament in the semen of horses; and Professor Fleming, of Kiel, has also confirmed Dr. Gibbes's observations, both as to the existence of this filament, with its mesentery, and the different reaction to staining fluids of the head and middle part of spermatozoa.

THE DUCHESS OF WESTMINSTER.

THE illness of the Duchess of Westminster has, we believe, been due to cardiac obstruction, with the symptoms commonly called cardiac asthma. The condition has obviously created anxiety, but by absolute rest there has been during the last week an improved state of the circulation, and it may be hoped that this will continue.

STIMULANTS IN WORKHOUSES.

REFERRING to our recent article on Alcohol and Hospitals, Mr. Alpass, one of the Toxteth guardians, shows that in their workhouse, with an average of 320 inmates under medical treatment, the total cost of stimulants during the last quarter had been £1 18s.; for out-door cases the total cost of stimulants was 5s. 4d. Mr. Alpass does not say whether any pressure had been put on the medical men in this matter, or whether their action was entirely spontaneous; neither does he accompany his statement with any particulars of disease and mortality. Our opinion is strong in regard to pauper dietaries—that, if beer and spirits are withheld, the money which the use of them would have cost should go to the improvement of the diet.

A CONTRAST.

AT the examinations for the first half of the diploma in surgery of the Royal College of Surgeons in Ireland, which terminated last week, more than 50 per cent. of the candidates were rejected for insufficient answering; while, on the other hand, of twenty-four candidates who presented themselves this month for the licence in medicine of the College of Physicians in Ireland, all were successful.

A PRIVATE dissecting-room, duly licensed, in the old, disused burial-ground of St. George-the-Martyr and St. George, Bloomsbury, in the parish of St. Pancras, has been made the subject of local complaint for nuisance, and generally it has been sought to excite popular prejudice against it as "a scandal." The room (a temporary building standing in the burial-ground) has been inspected by the three medical officers of health of St. Pancras, Holborn, and St. Giles, and found to be free from anything that could act injuriously on the public health. The burial-ground belongs to the Holborn Board of Works, and it is understood that Dr. Septimus Gibbon, the medical officer of health of the Board, will be instructed to maintain a general supervision over the building in the interest of the public health.

GENERAL SKOBELEFF reports that on the 3rd instant Dr. Studitsky, of the Red Cross Society, was despatched from Bami to Bendessen with an escort of twelve Cossacks, for the purpose of examining the body of a Cossack killed on the road on the 1st inst.; they were surrounded by a body of Tekkés numbering about 300, and at once attacked, and for eight hours exposed to the cross fire of the enemy; a company of infantry came to the rescue, and after a hand to hand encounter were defeated. Dr. Studitsky was unfortunately slain with two comrades. The Emperor, on receiving the report, ordered all the surviving Cossacks to receive military decorations.

AT a meeting held in connexion with the Order of St. John of Jerusalem on Wednesday, at Bolton-row, Mayfair, Dr. Sieveking delivered a lecture on "The Employment of the Hospital Patient after his discharge." The lecturer said few things were more distressing to the thoughtful physician in his hospital ministrations than the knowledge of the unfitness of many of his patients, after their discharge, for the duties of the calling in which they had been placed. The matter was referred to the Ambulance Department of the Order.

THE gold medal of the British Medical Association has been awarded by the Committee of Council to Dr. William Farr, F.R.S., D.C.L., C.B., as an expression of their high appreciation of his long, unwearied, and successful labours in behalf of statistical and sanitary science, as a recognition of the light he has thrown upon many physiological and pathological problems, and on account of the extraordinary services his work has rendered to the advancement of the health of the nation.

ON Saturday last, at the Charing-cross Hospital, Mr. Barwell extirpated the left kidney of a girl aged sixteen, the removal being effected through an opening at the loin. Long-standing and severe suppuration had greatly reduced the patient's strength. The organ was large (six ounces and three-quarters), tuberculous, and suppurating. Since the operation the patient has been doing so well that hopes of her recovery are entertained.

THE appointment of a commission to report on medical aid and poor-law relief in the Isle of Man seems to have provoked considerable hostility in the island. A vote of censure on the Governor for the part he has taken in the matter appears to have been threatened, which induced that functionary to inform the Manx Legislature that if such a course were adopted he would place his resignation in the hands of the Imperial Government pending inquiry.

A "Society for the Advancement of Oral Science" has been started in America. It is based on the principle that all practitioners in the dental art should be diplomated members of the medical profession. Article III., Sect. 4, in its constitution, provides "that every person practising any department of medicine should be a graduate of some reputable medical school." The President is Dr. Joshua Tucker, and the Secretary Dr. W. H. Rollins.

THE first meeting of the Court of the Victoria University took place on the 14th inst. at Owens College, Manchester. Amongst other appointments, Professor Roscoe, of Owens College, was chosen pro-vice-chancellor for the term of vice-chancellorship. The Chancellor (the Duke of Devonshire) and the other authorities of the University were in the evening entertained at a banquet in the town-hall.

MADAME SKOBELEFF, the murder of whom near Philippopolis has created so much grief and indignation, had been most active in organising schools and hospitals at Constantinople and elsewhere. At the time of her assassination she was, it appears, on a journey from that city, supplied with money and medical necessities for the benefit of the hospital at Tchirpan.

THE death of Dr. Arnold Beer, at the Grand Hotel, Paris, on the 13th inst., at the age of forty-five, is announced. Many years ago he relinquished the practice of medicine to engage in the pursuit of general literature, of which he was a distinguished ornament.

MR. HENRY FROWDE asks us to notice that the Queen has been graciously pleased to accept copies of the special editions of the Oxford Bible for teachers, which have been printed to commemorate the centenary of Sunday schools.

AT a general meeting of the members of University College, Sir Julian Goldsmid, Bart., was elected treasurer of the College, in place of the Right Hon. G. J. Goschen, M.P., who has resigned.

A BILL to amend the law in Ireland relating to the registration of births and deaths, and a Bill entitled an Act for taking the Census of Scotland, have been issued.

IN the despatches of Lieut.-General Sir F. S. Roberts, commanding the Cabul Field Force, amongst the officers reported as having done good service at the operations at Charasiah on the 25th of April last, are included the names of Surgeon J. Lewtas, M.B., Corps of Guides, and Surgeon J. J. Morris, M.D., 92nd Highlanders.

AT a late meeting of the Manchester Geological Society an ingenious instrument, termed a "spark tube," was exhibited and explained by Dr. Angus Smith. The object of the apparatus is to indicate the presence of inflammable gas in mines.

The Lancet Commission ON THE MEDICAL USE OF WINES.

III. RED BORDEAUX WINES.

THE enormous number and variety of true red wines from the Gironde, most of which are now freely imported into this country, make it a task of no small difficulty to discuss their medical value and uses. This wide range of selection has recently been brought before us in a most striking manner, by contrasting the price of a *vin ordinaire* of the cheapest and commonest type (10*d.* or 1*s.* per bottle) with the sums that well-matured wines of the best vintages may command. At a sale by public auction during the present month, Léoville Lascazes' (1864 vintage) was sold at £10 per dozen, whilst Château Latour (1858 vintage) reached the almost fabulous price of £12. The patient's daily question, "What shall I drink?" requires more consideration than is usually devoted to it before the medical adviser gives the stereotyped reply, "Oh, you can take a little claret." For more than a century the various vineyards on the different estates of the Médoc district have been classified in five great classes. The first class comprises only the three great vineyards, Château Lafite, Château Margaux, and Château Latour; the second class includes sixteen vineyards, of which the best known in England are perhaps Mouton, Rauzan-Gassies, Léoville-Lascazes', Cos d'Estournel, and Pichon-Longueville; the third class, thirteen in number, includes Lagrange, Giscours, Brown-Cantenac, &c.; the fourth class, eleven in number, embraces St. Pierre, Château Beychevelle, Duhart-Milon, La Tour-Carnet, &c.; whilst among the best known of the seventeen in the fifth class are Pontet-Canet, Batailley, Camensac, and Clerc-Milon. To the general public the mere name of these vineyards is of scarcely any value, even if the accuracy of the label on the bottle can be assured, for much depends on the year in which the wine is produced and the period at which it has been bottled. Besides the wines admitted into the great classes, there are many others produced on estates in the Médoc district, cultivated by the *bourgeois* proprietors; and although these take a lower rank in the estimation of the wine-importer, they are, especially in good years, often as sound and good as those which have been fortunate enough to secure an entrance into the classified lists. Still cheaper clarets are bought from the peasant-proprietors, and these form the *vin ordinaire* or Médoc which is supplied to everyone with his meals at the French restaurants. It has been estimated that of the total yield of wines in an average year, the classed wines form only 2 per cent., the superior table wines 12 per cent., the medium 20 per cent., and the *vins ordinaires* the remaining 66 per cent. Besides names derived from the estate, other clarets are merely marked with the name of the commune in which the wine has been grown, such as St. Julien, St. Estèphe, or Margaux. As far as the classified wines are concerned, none are to be trusted without the brand of the estate; of the others with simply the name of the commune, the veracity and knowledge of the importer form the only guarantee for the purchaser. As a rule, the name of the commune is put on to indicate rather a certain class and price of wine than to show its place of growth.

Too frequently for market purposes the different wines are blended, so that except under special circumstances, or by securing a classified wine, a pure growth is unattainable. As an additional precaution, we may mention that adulterated claret is common enough in the market, and this must be particularly borne in mind when the cheaper varieties are recommended. Such mixtures are usually compounded of water, alcohol, and cheap Spanish wine, with a small quantity of sour claret added thereto. In true claret the taste is astringent and subacid, never really sour, and even in the roughest samples the peculiar vinous bouquet is well-marked. The date of the year of vintage, not mere age, is all-important in regard to the quality of claret; and of course this can only be known with certainty when the buyer purchases his wine on the spot from the grower, and lays it by himself for future use. Red clarets with much tannin and an average percentage of alcohol require to be kept for ten or twelve years, that they may fully develop their best qualities, and their market value increases with their age. The best vintage of late years has undoubtedly been that of 1875, and next to that 1870, 1868, and 1865, until we go back to the exceptionally fine year of 1864.

The clinical value of red clarets is exceedingly great, and every therapist is fully aware of the marked benefit that is derived from their use in most cases in which tonics are indicated. There are few conditions in which they really disagree, if taken in ordinary quantities. Their especial value consists in the fact that when taken with the meals they are true tonics, and have neither a stimulating nor a sedative effect. Even the higher-priced red clarets are much less stimulating than the Sauternes, and of course cannot be compared for a moment in this respect to either the red or the white Burgundies. The tonic effect of claret is due most probably to the peculiar combination of tannin with a certain but low percentage of alcohol, and it is remarkable how little variation in chemical composition exists between true red clarets, although the price differs very greatly. The year of vintage, the age of the wine, and the characteristics of the vineyard, by determining the bouquet and fragrance of the wine, enhance the price, but interfere only very slightly indeed with its chief constituents as far as can be shown by chemical analysis. In cases of anæmia, ordinary debility from overwork, feeble digestion, &c., a sound red claret is almost as good a prescription as most of the tonic drugs in the Pharmacopœia, and is always an advantageous adjunct to this class of remedies. Of course, it must only be taken with the meals, and in no case should more than half a bottle be permitted with the meal. In this quantity the amount of alcohol is very small, as may be seen by the analyses. In addition to the tonic properties of red claret, its value in increasing the appetite and aiding digestion is of great importance. Many patients who can eat but little, and so lose strength, especially in hot weather, improve very much if they take wine with their meals, and for this purpose claret is especially suitable. The percentage of grape-sugar is very small indeed; it is much less than in ordinary Sauternes, or white clarets, although not so small as in the specimens of Chablis and Meursault, to which we referred in our former article. Hence the diabetic patient may safely take an occasional wine-glass of red claret, and there is this special advantage—that he need not be prohibited from the more expensive wines of this class, whereas Sauternes and white Burgundies of high class would inevitably increase his malady. Clarets are generally spoken of as "sour" wines, and avoided by the gouty and rheumatic; but this is certainly a mistake. The amount of fixed acid is less than in most wines, and the low percentage of alcohol is a still further advantage in such cases. In several cases of atonic goat a glass or two of good claret daily has been taken with great benefit, although the patients may have been told that whisky, gin, and brandy were the only permissible forms in which they should take alcohol. In the treatment of persons with a tendency to obesity claret, as is well known, is particularly useful, and this is doubtless also, in part at least, due to the absence of any amount of unfermented sugar. The amount of tannin sufficiently explains the astringent character of red wine, and this is of great advantage in treating cases of atonic and so-called bilious dyspepsia, anæmia, and patients with any tendency to relaxed or chronically congested mucous membranes. It is this astringency which clinically separates the thin red clarets from the thin white ones, and renders them available for so many more forms of disease. Of course, if diluted

they are as grateful as refrigerants in cases of fever and in hot weather as are the corresponding white varieties.

As an example of the cheapest clarets—a little too rough for ordinary use, except diluted, but then a pleasant aid to digestion—we selected for analysis Gilbey's Castle A claret at 12s. per dozen.

With the exception of a specimen of Cos d'Estournel (*vide analysis*), this wine gave the largest percentage of tannin, and the fixed acid is also rather above, whilst the grape-sugar falls below the average. For every-day use it is greatly improved by dilution with an equal quantity, or even more, of water or one of the natural mineral waters. Cheap clarets, varying in price from 12s. to 16s. per dozen, have been submitted to us by many other merchants [Feltoe, McGavin and Co., Fidler], and have much the same characters as the above.

Medium-priced wines, varying in cost from 18s. to 24s. per dozen, are especially numerous and important; of these typical specimens have been submitted [Gilbey, Ward, Barnard, Feltoe, Campbell, and Massingham]. Some of these were merely labeled claret, others St. Estèphe, St. Julien, &c.; whilst those submitted by Ward and Gilbey were respectively marked Château Quinsac, 1875, and Château Loudenne, 1875. Although these specimens differed very much in body and bouquet, the proportions of the chief constituents approximated very closely, as seen by the following analyses:—

	(I.)				
	Superior dinner claret [Feltoe].	Château Loudenne [Gilbey].	Château Quinsac [Ward].	Claret M. 1875 [Massing- ham].

The classified wines submitted for examination varied greatly in price according to the class and year of vintage, from a wine of the fifth class, Pontet-Canet [Barnard], at 30s. per dozen, to such remarkably fine specimens as Cos d'Estournel in the second class [Denman], 1869 vintage, at 72s., and Château Lafite [Gilbey], 1875 vintage, at 78s. per dozen. The superior flavour, soundness, and bouquet of these classified wines need scarcely be mentioned, but we were scarcely prepared to find how little they differed in chemical analysis from the cheaper unclassified varieties. The analysis of a Duhart Milon [Barnard & Co.], 1875 vintage, at 48s. per dozen, may be taken as a very favourable specimen of these classified wines, for this vineyard is a well-known member of the fourth class.

Good sound red Bordeaux wines evidently differ very little in rough analysis, and a patient may take either the cheaper or the more expensive varieties without running any risk of their having different medicinal effects, provided he is

satisfied that he is dealing with a true and not a manufactured claret. The seven analyses which we have given as typical of wines of different degree, from the high-priced classified samples to the cheapest *vin ordinaire*, show a difference of only 1·3 per cent. by volume of absolute alcohol (from 10·21 volumes to 11·52), of 1 per cent. in tannin, of 0·05 per cent. of grape-sugar, and 7 per cent. of fixed acid, whilst the sum of total solids only varies from 1·64 to 2·14 parts in 100 volumes.

The importance of this constancy in chemical composition is the more striking if we compare it with the great variability that is shown by the different typical samples of the white Bordeaux and white Burgundy wines which we have referred to in our previous articles. It is obvious that in choosing a red claret, diabetic, gouty, rheumatic, dyspeptic, or anæmic patients have a much more extensive range, with perfect safety, than they possess if the white wines have been ordered for their malady.

It is generally considered that the wines from the Château Haut Brion and from the St. Emilion district contain more alcohol and tannin than red clarets in general, but we had no certified specimens submitted to us for analysis.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

West Sussex Combined Sanitary District (population 85,102).—This district includes the sanitary districts of Steyning (rural), Horsham (rural), Petworth (rural), Thakeham (rural), East Preston (rural), Midhurst (rural), Worthing (urban), Littlehampton (urban), and West Worthing (urban). Dr. Kelly's report for the year 1879 (his sixth annual) is of exceptional interest. In it he endeavours to determine by a closer analysis of the mortality of the several districts in his combination, and particularly of the mortality from zymotic diseases, from consumption, and from lung disease, what progress, if any, has been made in their health condition since he became medical officer of health to them. After a fashion he balances his five years' health accounts, setting an example which we shall hope to see generally followed by medical officers of health, and doing this in so thoughtful and far-seeing a fashion as to give to the effort a value far beyond its local bearing. Nor is this all. The report contains very much that is interesting and instructive relating to the sanitary administration of the several districts in combination. To do justice to the report, each district should be considered apart, but space restricts our observations upon it necessarily to the part which deals with the district as a whole. We note simply in passing the diminution of the general mortality of the combined district in recent years, and the low infant mortality, and direct our attention to the observations on zymotic or catching disorders, and on phthisis and lung diseases. The mortality returns for the district show a very marked decrease during the current decade in the prevalence of zymotic disorders—a decrease, however, which Dr. Kelly points out is not peculiar to his district, but has been noted throughout the kingdom, and he adds, "whether these disorders are less prevalent than at former periods, or whether, the cases of disease being as numerous, the fatality is less, is a point which cannot be decided unless the total number of cases of sickness were known." With regard to the particular diseases observed in the district, Dr. Kelly's observations on diphtheria are of most interest. He describes this disease as occurring in two classes of cases, to wit (1) those which seem to depend upon inhaling sewer-gas, and where the patient suffers from a form of blood-poisoning; and (2) those which seem to occur independent of any defective drains or water-supply, and which are most common in bleak and exposed situations. On the form of the disease observed in the second class of cases, Dr. Kelly observes that unlike the cases in the former class (which are generally found as house-epidemics) they appear in an epidemic form, and that, associated with the more severe and well-marked cases, several other persons are attacked with sore-throat, about which no thought is

taken. Dr. Kelly's observations on this subject deserve careful attention. Neither the drainage, nor the water-supply, nor the milk-supply, Dr. Kelly states, seems to afford any due explanation of the prevalence of this disorder in one district more than another. A comparison of soils, however, seems to show that it is far more frequent on the Weald clay than elsewhere, and next upon the greensand, where this formation crops out just above the impervious gault. Dr. Kelly adds an interesting table showing the distribution of the mortality from diphtheria in his district with reference to different soils. Dr. Kelly has also much that is of interest to say with reference to the distribution of the mortality from phthisis and its relation to soils. But first he shows that there has been an "enormous reduction of the death-rate from consumption" in his district. A marked diminution of mortality from this disease has also not been peculiar to the district, but has been common to England and Wales generally. In town districts it might have been, perhaps, reasonable to attribute much of this decrease to works of drainage, but in the rural districts under Dr. Kelly's observation, he says "there has been no change whatever in the drainage, and as far as the subsoil water is concerned the houses are in much the same state as they were twenty years ago." Dr. Kelly is disposed to assign the decreased mortality in the rural districts to the improved state of the cottages, the rise of wages leading to the children being better clothed and fed, and to the increase of railway communications, which tends to diminish intermarriages, and to cause more interchange of population. He thinks that the examination of the more recent mortality statistics as to phthisis in his district, and of the distribution of the deaths, do not altogether bear out the views of those who maintain that dampness of soil and phthisis are intimately related, and he has some important observations on this subject.

The Stratford-on-Avon, Evesham, and Alcester Combined District.—Mr. G. H. Fosbrooke's reports for 1879 to the several authorities of the combination for which he acts as medical officer of health are now before us, and prove that a sure, if somewhat slow, progress is being made in the sanitary administration of the different districts.—*Stratford-on-Avon (Urban)* which is about to merge the lesser dignity of a Local Board into the higher dignity of a Corporation, awaits the completion of the next census before entering upon calculations as to its existing rate of mortality; but the relatively small number of deaths among children under one year of age suggests that the rate when determined will prove low. The year saw the end of an epidemic of scarlet fever which had been fatal the previous year. The sewerage of the town has been extended, and the method of excrement disposal improved.—*Evesham (Urban)* had a population of 4588 in 1871, and Mr. Fosbrooke holds the population to have been stationary since then. The rate of mortality was 20·6 per 1000 population in 1879, as compared with 19·6 in 1878. The rate of mortality among infants is described as excessive, and is attributed to "insanitary surroundings, climatic influences, ill-chosen and improperly-administered food, overcrowding, &c." Mr. Fosbrooke observes that the sanitary authority has taken no action under the Adulteration Act, and urges them to do so. Much bad house-accommodation and overcrowding appear to exist in the district. An outbreak of typhoid fever, numbering thirty-three cases, of which six proved fatal, and which was due to impure water, was made the subject of a special report.—*The Stratford-on-Avon, Evesham, and Alcester Rural Sanitary Districts.* These districts have a combined population of 44,000 (1871), and had in 1879 an average annual rate of mortality of 17·9 per 1000 population. The general report on the districts shows that a good deal has been done towards getting their sanitary administration into systematic working order, by means of a house-to-house survey, the adoption of urban powers for various purposes in several places, inducing medical practitioners to inform the authorities as to the existence of cases of infectious diseases, the establishment of an infectious diseases hospital ("sanatorium") at Alcester (the establishment of other hospitals is held over, it would appear, until the final decision of the Courts of Law in the Hampstead Hospital case is arrived at), the extension of good systems of water-supply, the sewerage of numerous towns and villages, the improvement of house-accommodation, diminution of overcrowding, and large abatement of nuisances. We quote from the report the following statement of results of observation on diphtheria by Mr. Fosbrooke in this district:—

"1. That it is more liable to appear and spread in rural than in urban districts. 2. That geological position has little, if any, connexion with the disease; but that local influences of various descriptions have a most important relationship to it, for it is marvellous how diphtheria, when once fairly established, persistently clings to the *immediate neighbourhood*. 3. That 'dampness of site' does not in my experience bear that intimate relationship to the disease that some very competent observers are prone to believe. 4. That the dissemination of diphtheria is not dependent upon 'seasons,' and that excessive 'rainfall' does not *materially* influence the disease. 5. That 'age' is a predisposing cause; infants under one year being less susceptible than children of any other age, and that the greatest incidence is in children above five and not exceeding nine years. 6. That 'family susceptibility' is an important predisposing cause, although not a few instances have come under notice in which one child *only* of a large family living under precisely similar conditions has been attacked. 7. That the younger the child the less the chance of recovery. 8. That 'sex' has no material influence on it. 9. That it can arise *de novo*, and that all insanitary conditions, particularly polluted water, are often intimately associated with its origin and dissemination. 10. That it is *most infectious* and should be so treated from the first; further, that it can be transmitted by a person who has not had the disease, and clings to some dwellings with great pertinacity. 11. That 'schools' very frequently distribute the disease in a wholesale manner. 12. That the disease, in my experience, has not been caused or distributed by unwholesome milk. I have mentioned the preceding facts (admittedly in an imperfect manner) because I feel that all observations on outbreaks of diphtheria should be recorded, as the etiology of the disease is shrouded in obscurity."

FEVER IN IRELAND.

Two Parliamentary papers have been published relating to the subject of "fever" in the distressed districts in Ireland, one being a report by Dr. Nixon, temporary medical inspector to the Local Government Board (Ireland), on an outbreak of fever in the Swinford Union, County Mayo; the other two reports by Dr. Stewart Woodhouse, temporary medical inspector to the same Board, on outbreaks of "fever" in Kilglass and Castleconnor, both in the county of Sligo. In the Swinford Union Dr. Nixon found typical maculated typhus. From the 3rd June to the 1st July fifty-five cases had been admitted into the fever hospital, the greatest number (twenty-five) during the week beginning the 24th June. Dr. Nixon visited four districts and found there four cases of typhus, but it does not appear that any active extension of the disease was going on among the population. Of 142 cases of fever which had occurred in the parish of Kilglass, Dr. Woodhouse reports that five only were typhus, the remainder being either enteric fever or simple febricula; of thirty-two cases at Castleconnor, all had been either enteric fever or febricula, not one being typhus. Neither Dr. Nixon nor Dr. Woodhouse found any indications of relapsing fever. Dr. Woodhouse lays considerable stress upon the continued use of Indian meal in the districts he visited, unvaried with any other article of food, as a predisposing cause of fever; but although this would appear to have been the staple food in some places for eight months no word is said of *scurvy*. The present reports have been, however, called for in haste to satisfy the public anxiety as to fever specially. We shall look with interest for further more detailed reports, and not without uneasiness in regard to *scurvy*.

Dr. Sigerson and Dr. J. E. Kenny have also reported to the Dublin Mansion House Committee on the fever prevalent in the distressed districts in County Mayo visited by them. They describe the fever as maculated typhus, confined to the distressed families, and have no hesitation in attributing its prevalence to the distress.

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

We learn from this report, which is of considerable interest at the present time, that the average daily number of persons receiving relief in workhouses during the year was 51,946, being an increase of 3952 over that of the previous year; and out-door relief 36,629, or an increase of 3355. During the year 58,583 persons were under treatment in the workhouses for various affections, including 8285 cases of

fever or other contagious disease, with a mortality of 13,127. Last year 471,277 new cases were attended by dispensary medical officers at the various dispensaries throughout the country, and 200,979 were treated at their own homes, forming a total of 672,256; while 126,911 people were vaccinated or revaccinated during the same period. The total cost of the dispensary districts for the year ending September 29th, 1879, was £146,030, which includes cost of medicines and medical appliances, salaries of medical officers, apothecaries and midwives, rent of dispensary buildings, vaccination fees, &c. The total expenditure of poor-rates for all purposes—viz., relief, medical relief, burial-grounds, registration of births, deaths, and marriages, sanitary measures, &c., was £1,119,755, being a decrease in the total expenditure of £4466 as compared with the previous year. During the year ending January 24th last 661 deaths from small-pox were recorded, of which number 112 took place in workhouses, against 254 in the preceding twelve months. The Board point out the advantage of having recourse to the section of the Public Health Act authorising the removal of persons to hospital where there is not sufficient home accommodation for the patient; and the section of the Act which prohibits the practice of holding "wakes" under a penalty of £5. There was an increase of 54 in the number of cases of fever attended by dispensary medical officers for the year ending September. Scarlet fever prevailed, there being 3008 cases treated by medical officers of dispensaries in 1879 as compared with 2118 in the preceding year; while 103 fatal cases took place in workhouses against 39 in 1878. The report refers to the provisions which were made for the requirements of the destitute poor, and states that although there has been much suffering and exceptional distress in many parts of Ireland, yet after careful inquiry the Commissioners found that privation did not reach starvation in any union, the alleged cases from this cause being on examination found to result from other causes.

ARTISANS' DWELLINGS ACT.

This Act is legally applicable to only six places in Ireland—namely, Dublin, Belfast, Cork, Limerick, Londonderry, and Waterford. During the past year an Improvement Scheme has been carried out in Belfast, and the street authorised thereby opened up for public traffic. With respect to the two unhealthy areas in Dublin with which the Corporation are dealing, the arbitrator has, in one case, that of the Coombe area, made his final award, and titles are being investigated; while in the Boyne-street area no steps have been taken to acquire the interests therein, but some of the dilapidated houses have been closed under the provisions of the Public Health Act as uninhabitable. In Cork there were seven areas, with respect to which representations were made. Maps, plans, and schedules have been prepared for taking compulsory possession of No. 1 area, and the arbitrator was to hold his first meeting last April. The sanitary authority have thought it more prudent to finish No. 1 before taking up the others, as there may be some difficulty in providing accommodation for persons who may be disturbed. No attempt has been made by the Corporations of Limerick or Londonderry to make use of the powers given by the Act; and although in Waterford the Act has not been applied as yet, the Corporation have erected labourers' dwellings under the provisions of the Act 29 and 30 Vict., cap. 44.

THE VACCINATION ACTS AMENDMENT BILL.

Lord R. Churchill, amidst the laughter of the House of Commons, put a question to the Government on Monday evening relative to the Vaccination Amendment Bill. Mr. Dodson, the President of the Local Government Board, having been unseated, his lordship asked if the Bill would be persevered with. Mr. Gladstone answered that he had not yet considered the question! This is probably the beginning of the end as regards this movement. It is much to be regretted that a question of such magnitude and importance to the public health should be repeatedly stirred and unsettled.

A member of the Poplar Board of Works, at a recent meeting of the Board, drew attention to the fact that among the crowd of applicants for out-relief gathered at the relief office on Monday, there were a husband and wife with two children, who had come direct from the room where another child was lying ill of scarlet fever. He thought that

arrangements should be made for preventing such risks of propagating disease, but does not appear to have given any indication of the sort of arrangements which would meet the difficulty—a difficulty felt not only in relief offices, but wherever people congregate together.

Mr. Watkin Williams has given notice in the House of Commons that he shall ask the Secretary to the Local Government Board whether any regulations exist defining the duties of relieving officers and medical officers of Poor-law Unions in relation to orders for the supply of medical necessities to the sick poor, and whether it is competent for relieving officers to disregard or overrule at their discretion the orders of the medical officers, and if so, whether the Local Government Board will consider the propriety of altering the regulation in question.

A Parliamentary Return has been published showing the number of notices served by the Conservators of the river Thames, under the Thames Conservancy Acts, for the discontinuance of the passage of sewage, or other offensive or injurious matter into the river above the intakes of the water companies supplying the metropolis, and the result of these notices.

The Chesterfield Rural Sanitary Authority, in view of the dissemination of scarlet fever from the careless exposure of convalescent children by their parents, decided to prosecute in one case, as a warning to others.

VITAL STATISTICS.

HEALTH OF LARGE ENGLISH TOWNS.

Notwithstanding a marked increase in the fatality of infantile diarrhoea the rate of mortality in our largest towns continues considerably below the average. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4748 births and 2892 deaths were registered last week. The births were 237, and the deaths 383, below the average weekly numbers during 1879. The deaths, however, showed a further increase of 232 upon the exceptionally low numbers returned in recent weeks. The annual death-rate per 1000, which had been equal to 18.9 and 19.2 in the two preceding weeks, further rose last week to 20.1. During the thirteen weeks of last quarter the death-rate in these twenty towns averaged only 20.4 per 1000, against 23.3, 22.7, and 22.2 in the corresponding periods of the three years 1877–8–9. The lowest death-rates in the twenty towns last week were 15.6 in Portsmouth, 15.7 in Leicester, 15.9 in Bristol, 16.6 in Salford, and 16.7 in Hull. The rates in the other towns ranged upwards to 23.0 in Plymouth, 23.7 in Sunderland, 24.9 in Oldham, 25.8 in Liverpool, and 27.4 in Norwich. The high rates in the three last-mentioned towns were mainly due to excessive zymotic fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 522 in the five preceding weeks, further rose to 567 last week; these included 258 from diarrhoea, 117 from scarlet fever, 86 from whooping-cough, and 53 from measles. The annual death-rate from these seven diseases averaged 3.7 per 1000 in the twenty towns; while it was but 0.7 and 1.7 in Plymouth and Bristol, it ranged upwards in the other towns to 6.3 in Oldham, and 9.7 in Norwich. Scarlet fever showed the largest proportional fatality in Norwich, Oldham, and Bradford; measles in Sunderland, and whooping-cough in Liverpool. Eleven deaths were referred to diphtheria in London, 3 in Birmingham, and 2 in Leeds. Small-pox caused only 3 deaths in London, and not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the two preceding weeks had declined from 237 to 191, had increased again to 200 on Saturday last; 30 new cases of small-pox were admitted to these hospitals during last week, against numbers declining from 50 to 17 in the four preceding weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

Last week's returns afford evidence of the commencement of the usual summer fatality of infantile diarrhoea. The deaths referred to diarrhoea in the twenty towns, which in the four preceding weeks had steadily increased from 51 to 183, further rose last week to 258, including 165 in London. The annual death-rate from diarrhoea last week was equal to 2.3 per 1000 in London, but did not average more than 1.3

in the nineteen provincial towns; among these nineteen towns the highest death-rates from diarrhoea were 2.0 in Leicester, 2.1 in Hull, 2.3 in Oldham, and 3.6 in Norwich.

The deaths referred to diseases of the respiratory organs in London, which had steadily declined in the five preceding weeks from 230 to 171, were 173 last week; they exceeded, however, the corrected weekly average by 13. The annual death-rate from diseases of this class did not exceed 2.5 per 1000 in London; it was equal to 4.9 in Liverpool, and to 2.5 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18.6 per 1000, against 20.9 and 20.4 in the two preceding weeks; this rate was 1.5 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 12.5 and 13.6 in Greenock and Perth, to 24.4 and 30.2 in Paisley and Leith. The 109 deaths referred to the seven principal zymotic diseases in the eight towns, showed an increase of 12 upon those in the previous week, and included 38 from diarrhoea, 21 from scarlet fever, 21 from whooping-cough, and 18 from measles, while but five deaths were referred to fever, showing a marked decline from recent weekly numbers. The annual death-rate from these seven diseases averaged 4.4 per 1000 in the eight towns, against 3.9 in the twenty English towns; this zymotic rate ranged from 0.0 and 0.7 in Perth and Greenock, to 8.0 and 9.6 in Leith and Paisley. The fatal cases of diarrhoea in these eight Scotch towns further rose from 25 and 36 in the two preceding weeks to 38, and were equal to an annual rate of 1.5 per 1000, against 1.8 in the English towns; the largest proportional fatality occurred in Leith and Glasgow. The deaths from whooping-cough showed an increase, which was marked in Paisley; those from scarlet fever were also more numerous in Edinburgh and Leith. Sixteen of the fatal cases of measles were recorded in Glasgow. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight Scotch towns, which had been 91 and 90 in the two previous weeks, dropped to 58 last week, which was equal to an annual rate of 1.9 per 1000. The rate from the same diseases in London was equal to 2.3. The annual death-rate in the eight Scotch towns during last quarter averaged 23.3 per 1000, exceeding by 2.9, or 14 per cent., the rate in the twenty English towns during the same period.

THE HEALTH OF DUBLIN.

The rate of mortality in the City of Dublin, which had ranged in the five preceding weeks from 42.5 to 31.2, further declined last week to 30.3, a lower rate than has prevailed in that city in any week since the beginning of November last. The unsatisfactory sanitary condition of Dublin may, however, be inferred from the fact that during the thirteen weeks of last quarter the annual death-rate averaged 36.6 per 1000, against 19.4 in London, and 22.4 in Edinburgh. The 183 deaths in Dublin last week included 45, or 25 per cent., which were referred to the seven principal zymotic diseases, against 53 and 47 in the two preceding weeks; 10 resulted from small-pox, 11 from whooping-cough, 8 from scarlet fever, 6 from fever (including typhus and typhoid), and 6 from measles. The annual death-rate from these seven diseases was equal to 7.5 per 1000 in Dublin, against 4.5 in London and 4.1 in Edinburgh. The fatal cases of small-pox have shown a decline during the past three weeks, but no less than 135 were recorded in the thirteen weeks of last quarter, against 79 and 61 in the two preceding quarters.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE OUTBREAK OF ENTERIC FEVER AT POSSILPARK, GLASGOW.

Dr. James Christie's report to the local authority of Barony on the outbreak of enteric fever at Possilpark, one of the suburbs of Glasgow, in April and May of the present year, has now been published. This outbreak was a part of the series of outbreaks which occurred in Glasgow at the same time, traced to infected milk, and of which a detailed account has been published by Dr. J. B. Russell, the medical officer of health for Glasgow. The Barony authorities re-

quested Dr. Christie to report to them on the particular prevalence of enteric fever affecting their parish, and from the beginning of the inquiry Dr. Christie was in communication with Dr. Russell on the relations of this prevalence to the occurrences of fever within the municipal boundaries of Glasgow. A comparison of notes made it evident that the outbreak in Barony parish was closely connected with the outbreaks in Glasgow, and that there was probably a common cause of the several outbreaks which was to be sought in an infected milk-supply. This part of the investigation was left to be followed out by Dr. Russell, and his report shows how admirably this was done, and how completely the line of research indicated by the preliminary inquiries of the two reporters was justified in the result. Dr. Christie, in this report, does not go over the ground already traversed by Dr. Russell, which goes to prove the infection of the milk with enteric-fever poison, but contents himself with showing how the occurrences in Barony parish confirm from point to point the conclusions suggested by the occurrences in Glasgow. Dr. Christie's report completes the story in part told by Dr. Russell, and completes it well; and the two reports form one of the most interesting and instructive accounts we possess of a series of circumscribed outbreaks of enteric fever caused by infected milk.

THE POTATO.

The Select Committee on the potato crop have closed their inquiry and completed their report. They accept the opinions of the scientific witnesses examined by them, that the potato disease consists in the growth of a fungus (*Peronospora infestans*) in the plant, which spreads during the summer by means of spores, a single fungus producing millions of spores. They attribute the persistence of the disease to the degeneration of the older varieties of the plant, and look chiefly to the cultivation of new varieties as the chief mode of escape from future losses from it, or of diminishing its ravages. To this end they suggest the careful cultivation of new varieties by the larger potato growers and the agricultural societies, but having regard to the fact that little has as yet been obtained in this direction by these agencies, they hold that the time has come for Government to give assistance, and establish experimental farms in England, Scotland, and Ireland, for the cultivation of new varieties of potato.

INDIAN MEDICO-SANITARY NEWS.

We gather from our contemporary the *Indian Medical Gazette* that the profession in Calcutta are by no means unanimous in the conclusion that "The New Disease" in that city is beri-beri.—The Madras Sanitary Commissioner describes a peculiar and intractable form of ulcer as "universally prevalent in the districts lately subjected to famine."—A general census of India is to be taken in February, 1881.—It would appear that the mortality among seamen in the port of Calcutta is more than double that of the general population on shore. This excessive mortality is attributed to the influence of the foul water on which they live and exposure to night air. It is noted also that the fatality from cholera amongst sailors in the port is much greater than among the shore population. Efforts are being made to improve the sanitary condition of the foreshore on both sides of the river, and the practice of discharging the Fort sewage into the river is to be stopped. 105 human bodies and 2543 carcasses of animals were stopped and sunk by the river police during 1879, against 128 and 2528 in 1878.

THE SEWAGE OF PARIS.

The municipality of Paris are so satisfied with the results obtained by irrigation in the disposal of the sewage of the city, that they have determined to ask the Government for permission to increase largely the area of ground to be submitted to irrigation, and in other ways to facilitate the distribution of sewage to farms on the line of the outfall sewers.

At a recent meeting of the Whitechurch Local Board, the surveyor stated that Dr. Thursfield, the medical officer of health for the district, had said that none of the water in the town was fit to be used. The board thought the matter was of the greatest importance, and directed the clerk to write to Dr. Thursfield for him to make an analysis and report immediately.

Dr. Kay's report on the outbreak of fever at Waterberg, Transvaal, attributes it to the unhealthiness of the site, bad sanitary arrangements, and the exceptionally dry summer.

It has been decided by a majority of 96 votes to establish a Local Board in Dorking.

THE DISPUTE AT GUY'S HOSPITAL.

WE hope there may be ground for the anticipation that the unhappy disagreement between the Treasurer and the Medical Staff of Guy's Hospital is at an end. The Committee of Governors, which was appointed to inquire into the whole question of nursing, has made its report, after holding fourteen sittings, and after having examined the chief executive officers of the institution. This Report is fairly judicial in tone, and may, perhaps, prove conciliatory to those who have been aggrieved by the autocratic action of the Treasurer, especially as it is evident that if the suggestions of the Committee be acted upon the Guy's autocracy is dead, and its place will be taken by a properly-constituted Committee.

The Report states that the Committee is satisfied as to the *bona fides* of all who have taken part in this dispute; that a reform in the nursing of the hospital had become necessary, and that the supply of efficient nurses had become unequal to the demand, although "it may be admitted that many of the sisters and nurses heretofore attached to the hospital were capable persons, and attended to the sick with kindness, intelligence, and sympathy." That the new *régime* instituted in November, 1879, whereby the work, recreation, and supervision of the nurses were made conformable to certain rules and regulations, proved distasteful to many of the old nursing staff, "of whom many left the hospital rather than agree to them," and among them were "some persons highly valued by the Medical Staff." That the new arrangements are working fairly well, and that "in about two-thirds of the wards there is now no dissatisfaction." That "there is no valid reason for believing that in any case is interference with the orders of the Medical Staff either sanctioned or connived at by the Matron," and that "there is no reason to think that the present nursing arrangements put any real hindrance in the way of medical observation or practice on the part of the students."

With regard to the manner in which the recent changes were introduced the Committee is of opinion that this was done "without sufficient consultation and preparation, that some details were unduly insisted upon, and that much misapprehension ensued."

"The Matron was not personally introduced to the Staff. She was apparently authorised to frame rules, on which the Staff were not consulted, but which, in their opinion, affected the medical treatment of the patients. The Matron herself understood that no further authority than that of the Treasurer was required; and he, on his part, was under the impression that the changes contemplated would be acceptable to the Medical Staff. The Committee cannot feel surprised that the Staff resented the publication of the article on the crisis at Guy's Hospital in the April number of the *Nineteenth Century*, which they deemed to be an attack from within the walls of the hospital, on their professional honour, but the Committee have no evidence that anyone now in the hospital was responsible for the article, or had any knowledge of its contents before it was printed. The Committee are firmly convinced that the Treasurer, the Medical Staff, and the Matron have had the same object in view—viz., to promote the good of the hospital and the comfort of the patients. It is, however, essential that there should be no bar to frank personal communication between those who are practically engaged in arduous duties involving complicated arrangements, and provision for sudden emergencies. The Committee cannot find sufficient justification for the difficulties which have existed between the Medical Staff and the Matron almost from the date of her

entrance into the hospital, nor can they see, in the present state of feeling, any just ground for calling upon her to abandon the duties of a post which she did not seek, but which she was specially invited to undertake."

The Report finally deals with the question of remedies for the state of things which has arisen, and the proposals made seem to us to be suitable and adequate for the attainment of the ends proposed. The final clauses of the Report proceed as follows:—

"They understand that the Staff desire that no rules affecting their patients should be issued without their previous knowledge, that no one person should be supreme in the removal or dismissal of nurses without some appeal; and that the Staff should have some recognised right and a simple way of bringing their requirements before the Governors. The Committee, therefore, recommend that the Court should make such arrangements as may be necessary to render the attendance of the Governors at the Taking-in Committee more regular; and they would suggest that the best way to effect this purpose would be to abolish the old plan of two Governors coming on duty in rotation once a week, and to substitute instead the following arrangement. That each year not less than ten Governors be nominated as the Taking-in Committee for the twelve succeeding months, and that they be requested to make such arrangements between themselves and the Treasurer as will procure the attendance of at least two members at every Taking-in Committee. That once a month, or oftener if necessary, two members of the Medical Staff, appointed by that body, be invited to attend the Committee with the view of deliberating on any matters relating to the medical and nursing arrangements. That regular Minutes be kept of the proceedings of the Taking-in Committee, and that such Minutes be brought for confirmation before the next Court of Committees as the sole executive body authorised by Act of Parliament. That in any difference of opinion the views of the Medical Staff, as well as those of the Governors, be recorded on the Minutes. The Committee consider that the full reports at present laid before the Taking-in Committee might with advantage be supplemented, so as to embrace every matter of importance. The Committee believe that the above arrangement, while materially assisting the Treasurer, would enable the Governors to become more intimately conversant with the internal working of the Hospital, and at the same time it would afford the Medical Staff an opportunity (the want of which they have felt) of personally coming in contact with the Governors."

The Report is signed by Henry H. Gibbs, Charles Barclay, Trevor Lawrence, Richard M. Harvey, J. A. Shaw Stewart, Thomas Dyke Acland, Samuel Hoare (Chairman).

It is very easy to see that the Committee is of opinion that in the present day autocracy is an anachronism, and that the best intentions, coupled with a "plentiful lack of wit," are of all things the most likely to bring ruin upon ancient and valuable institutions. Guy's has passed through a period of great danger during the last few months, and has now, we find, emerged from it not altogether unscathed, but with the advantage of some guarantee against the recurrence of similar troubles. Possibly the question may now be allowed to rest, and the Medical Staff will consent to accept the decision of the Committee. While, on many grounds, it would have been well had the views of the Medical Staff received greater support, yet it would be gracious to lend a cordial support towards removing all friction that may interfere with the working of the newly constituted nursing machinery. If after a really fair trial it is found not to work satisfactorily, the new "Nursing Committee" will take cognisance of any shortcomings, and should this Committee do its work fairly and honourably, the necessity will not again arise for "washing dirty linen" in public, or for writing sharp articles in the pages of magazines.

MR. THOMAS JAMES SCHOLLOCK, M.R.C.S. Eng., L.S.A., has been elected Coroner for Guildford, Mr. T. Russell, solicitor, having resigned.

THE SERVICES.

SIR DONALD STEWART'S DESPATCHES.

THE *Gazette of India* has just published the despatches of Lieutenant-General Sir D. M. Stewart, K.C.B., reporting the success of his troops at the action of Ahmed Khol on April 19th, and in the neighbourhood of Ghuzni on the 23rd. After describing minutely the operations and dispositions, and bringing to notice the military officers who he considers did good service on these occasions, General Stewart adds, Paragraph 15: "The arrangements for the immediate care of the wounded reflect the highest credit on Deputy Surgeon-General A. Smith, C.B., the Principal Medical Officer with the force; and the exertions of the subordinate medical staff deserve my warmest acknowledgments." The casualties during the engagement amounted to—killed, 17; wounded, 124, of whom 9 are officers. More than 1000 dead bodies of the enemy were counted on the field, and their loss is estimated at from 2000 to 3000.

The Kandahar paper reports that fresh vegetables are very scarce, the supply for the troops being so small that the medical authorities are dreading an outbreak of scurvy.

DEATH OF BRIGADE-SURGEON HANNAN, A.M.D.

We regret to record the death at Simla, on the 12th June, from heat apoplexy, of Brigade-surgeon J. Hannan, Army Medical Department. Mr. Hannan served for many years in the 49th Regiment and in the Royal Artillery; and by his death the Army loses the services of a hard-working, painstaking medical officer. Mr. Hannan was unmarried.

ARMY MEDICAL DEPARTMENT.—Temporary Surg.-General Sir Anthony Dickson Home, V.C., K.C.B., to be Surgeon-General, vice Hampden Hugh Massy, M.D., C.B., granted retired pay; dated April 4th, 1880. Brigade Surgeon John Lyster Jameson to be Deputy Surgeon-General, vice Sir A. D. Home, V.C., K.C.B.; dated April 4th, 1880. Brigade Surgeon John Phillips Cunningham, M.D., to be Deputy Surgeon-General, vice G. Pain, granted retired pay; dated April 17th, 1880. The local rank of Surgeon-General conferred upon Deputy Surgeon-General John Andrew Woolfryes, M.D., C.B., C.M.G., in *Gazette* of Jan. 28th, 1879, is converted into temporary rank, but without pay or allowances; dated April 10th, 1880. Surgeon-Major John Meane to be Brigade Surgeon, vice Augustus Patrick Meyers Corbett, M.D., deceased; dated March 26th, 1880. Surgeon-Major Charles Carroll Dempster to be Brigade Surgeon, vice H. T. Reade, V.C., promoted; dated March 27th, 1880. Surgeon-Major William Henry Corbett, M.D., to be Brigade Surgeon, vice E. Y. Kellett, whose promotion has been cancelled; dated March 28th, 1880. Surgeon-Major Richard John William Orton, from half-pay, to be Surgeon-Major; dated June 18th, 1880. Surgeon-Major George Simon, M.D., has been granted retired pay, with the honorary rank of Brigade Surgeon; dated May 21st, 1880. Surgeon-Major William Langworthy Baker has been granted retired pay, with the honorary rank of Brigade Surgeon; dated June 10th, 1880. Surgeon-Major Alexander Campbell McTavish is granted retired pay, with the honorary rank of Brigade Surgeon; dated July 7th, 1880. Surgeon-Major Edward Denham Tomlinson is granted retired pay, with the honorary rank of Brigade Surgeon; dated July 7th, 1880. Surgeon-Major James Barry, M.D., retires from the Service, receiving a gratuity; dated June 1st, 1880. Brigade-Surgeon W. Macnamara, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Majors George Alexander Moorhead, William Jay, and Henry Harrison are granted retired pay, with the honorary rank of Brigade Surgeon.

Deputy Surgeon-General Cunningham, Army Medical Department, proceeds to Hong Kong on promotion, and relieves Deputy Surgeon-General W. A. Mackinnon, C.B., as Principal Medical Officer of the China command.

ADMIRALTY.—Staff-Surgeon James Devonshire has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet, with seniority of the 6th inst. Fleet Surgeon William Loudon Gordon, M.D., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, with seniority of the 16th inst.

Correspondence.

"Audi alteram partem."

COLOUR-BLINDNESS.

To the Editor of THE LANCET.

SIR,—In your issue of July 3rd, Dr. Joy Jeffries gives reasons for doubting the accuracy of my views as to the prevalence of colour-blindness. It is true that my examinations bear but an infinitesimal proportion in number to those of Dr. Jeffries, and that they have been made solely upon candidates for employment on the London and North-Western Railway. In the paper which he criticises I stated that one colour-blind was found amongst two hundred men consecutively examined by twenty-two coloured cards, aided by Stilling's coloured letters and squares. The discovery of so small a number, if colour-blindness be really so much more common, must have been due either to the insufficiency of the test, or to the fact that men with a knowledge of their own colour-blindness refrained from presenting themselves for examination and employment. This appears to me the more reasonable explanation, for I do not doubt the adequacy of the test, especially as the method of using it was precisely that on which Professor Holmgren lays stress—that, avoiding all names, the hand shall, by watching the colours, bear witness of the impression which the colours are making on the eye. That three-quarters of an hour were spent over one man is no evidence that the test is imperfect; nor do I gather from Professor Holmgren's writings that, even with his test—by far the best which has been yet devised—both time and patience are not occasionally required for the elucidation of the particular kind of colour-blindness, although the defective sense of colour may have been revealed almost as soon as the test has been begun.

The point of difference, however, between those who hold that every twentieth or twenty-fifth man is colour-blind, and those who find a difficulty in believing that this defect is so common, is a small one in comparison with the importance of a due recognition of colour-blindness in the examination of those who seek employment either by land or sea, where colours are the necessary signals of danger or otherwise.

The proposal to hold an examination at Cambridge has received the favourable consideration of the Executive, and it is hoped that no obstacles will arise in the way of carrying it out. An examination thus conducted must be of considerable value in arriving at an estimate of the prevalence of colour-blindness amongst an educated section of the community, and be the means of drawing greater attention to the subject than it has hitherto received in this country.

I am, Sir, your obedient servant,
New Cavendish-street, July 19th, 1880. HERBERT W. PAGE.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—On March 29th last I commenced the treatment of an ulcerated cancer of the breast with Chian turpentine in solution, the drug I used corresponding closely with Professor Clay's description of the pure kind.

After about twenty doses the patient was relieved from the lancinating pains which she had endured for many months, and these have not returned, though she sometimes complains of aching about the lower margin of the sore. The discharge, at first very profuse, is much diminished. When the case came into my hands, March 29th, the infiltration was threatening the axillary glands, but it certainly has been arrested in that direction, for they are perfectly free from disease, and the lines of tenderness and hardness which could be traced towards the axilla are no longer perceptible. The ulcer is considerably smaller than it was; the cancerous mass appears to be disintegrating and sloughing out from the centre, while along the upper border there is a firm cicatrix. The general health is decidedly improved, and the patient usually sleeps well. The only external applications have been Condy's fluid or sanitas, with occasionally a little tincture of opium to allay superficial smarting.

I should not have sought to publish this case at present, as it is too incomplete to justify any very definite conclusions,

but I think there would be cause for regret if the instances of failure recorded in THE LANCET should dishearten any who are trying a remedy with which Professor Clay has achieved such gratifying results, and I therefore offer my experience, as far as it goes, hoping that it may be accepted for as much as it is worth in support of a prolonged and thorough test.—I am, Sir, yours, &c.,

JOHN GILL, M.D.,
Surgeon to the Infirmary, Stratford-on-Avon.

June 29th, 1880.

THE DISPUTE AT GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—A writer in *Fraser's Magazine* has given to the public some valuable hints as to the causes of the existing state of things at Guy's. My object now is, while agreeing with him on the whole, to point out that, while mistaken in one case at least, he has also overlooked one strong argument against the system which it is now endeavoured to force upon the medical staff at Guy's. As an old student of King's, I look back with pleasure and satisfaction to the relationship which then existed between the medical and the nursing staffs. I hold that in a small hospital with a relatively large number of students a nursing sisterhood such as that of St. John's House is invaluable, both to protect the patients and help to maintain discipline.

On the other hand, in large hospitals such as Guy's, where students are sent that they may have practically the run of the wards, such a system would be both useless and injurious.

If women nurses are to be educated in strapping, dressing, bandaging, &c., as the writer in *Fraser* says is expected, let us all understand this, and room may no doubt be found for both nurses and students; but Guy's has not hitherto been used for such a purpose. I trust it never will be, for I now come to an important omission in the article already mentioned—viz., if a number of imperfectly (I put this mildly) educated women are to be allowed to practise upon hospital patients without either theoretical knowledge or even a determination to follow their so-called education to its legitimate end, what will be the result? I reply a large accession to the ranks of female quacks. Some of your readers, Sir, will laugh at this; but if so, they know not Manchester and similar manufacturing towns. Female quacks of all sorts and specialties abound here, and these have in the majority of cases been hospital nurses of the kind described, or at least mentioned above.

In conclusion, is it not time that the medical and surgical staff of other hospitals should express their opinion upon this matter? I venture to hope that neither my old teachers, fellow students, nor lady sisters would accuse me of any discourtesy to ladies, least of all to those who give their time, and often their money, to soothe the sufferings of the sick poor; but it is simply monstrous that one man should be permitted even to attempt to force a nursing system on the medical staff of Guy's against its will.

I am, Sir, yours truly,
Manchester, July 13th, 1880. H. STANLEY GALE.

To the Editor of THE LANCET.

SIR,—With reference to the letter from Guy's students to Mr. Brudenell Carter, which you kindly inserted in your issue of July 10th, will you allow me a line to state that it was signed by all the full surgeons, dressers, and by all the clinical assistants, in addition to the eight residents whose names you published. This will, I think, show that the sentiments expressed in the letter are felt by men throughout Guy's.—Your obedient servant,

W. HALE WHITE, M.B. Lond.
Guy's Hospital, July 14th, 1880.

THE CASE OF SALEWSKAL.

To the Editor of THE LANCET.

SIR,—In reference to the case of Salewskal you say, "on the whole this is the prettiest sample of crowner's quest law which we have encountered for many a long day." Allow me to add, that you are not alone in your opinion. Apart from the grounds on which you base the above statement, I hold that the ruling of the coroner was incorrect, and indeed illegal. The verdict was "wilful

murder" against Salewskal, and "gross neglect" against Dr. Buncombe. The latter part of the verdict was decided by the coroner to amount to manslaughter, and we therefore have presented to us this fact—that the unfortunate deceased must have been twice killed—viz., by murder and by manslaughter.

It is new to me, in a long experience, that there can be conviction for two separate forms of homicide, and that the death of one person can be caused by the two crimes of murder and manslaughter.

If Dr. Buncombe was amenable to the law for the death of deceased he could, in my opinion, have only been committed as accessory to the murder committed by Salewskal—*quod absurdum est*. If this was not the intention of the jury their verdict as affecting the doctor should have been treated as a censure, and sent by the Coroner to the Guardians for their investigation.—I am, Sir, yours, &c.,

A MEDICAL CORONER.

TEACHING AND EXAMINATIONS AT THE UNIVERSITY OF EDINBURGH.

To the Editor of THE LANCET.

SIR,—The case of the candidate at Edinburgh whose examination was arrested by the Professor of Practice of Physic must have been a very peculiar one. I know most of those who have recently passed that examination, and have heard of no such case as you speak of.

My own oral examination was conducted by the Professor of Clinical Medicine; and so far from avoiding subjects not discussed in the course I had attended, he questioned me chiefly on one of those very diseases; while the other two diseases about which questions were asked me had only been lightly touched upon.

I know that my own case has been by no means singular, and I think it only fair to the Professor that this should be known.

I am, Sir, yours truly,

July 13th, 1880.

CANDIDATE.

THE INTERNATIONAL MEDICAL ASSOCIATION.

To the Editor of THE LANCET.

SIR,—May I inquire who are the wire-pullers in the arrangements for the meeting of the International Medical Association for next year in London. As a teacher and physician in one of the leading London schools, and lately a president of one of the medical societies, I should have thought that I should have been asked to assist, with others of like standing, in the general arrangements. But I can glean no information from others. Yet, on the supposition that I am still President, I receive in virtue of that position a proof-list of the officers in the various sections, already out and dried.

It is also true that I was asked to subscribe to the reception fund; but names were already down for sums, and those are down as officers.

I protest, in the name of the various teachers and medical societies, against the cliquism thus shown. I ask why the general leaders of the profession are excluded from a voice in the matter?—I am, Sir, yours truly,

NEMO.

PARIS.

(From our own Correspondent.)

IN another column of THE LANCET will be found a biographical sketch of the late Paul Broca. Here I need only say that his premature death has been the chief topic of conversation in scientific circles, and that there are few without a kindly remembrance of the medical senator.

By Broca's death a number of official positions become vacant, and the most important of these is the professorship of clinical surgery at the Faculty of Medicine. For this chair several competitors are already mentioned, those having the best chances of success being MM. Tillaux and Bouchard. Another much desired, although less lucrative, appointment is that of Member of the Academy of Medicine, and for this M. Cusco is considered as the most likely candidate.

The readers of THE LANCET will be glad to learn that one of its most eminent contributors, Professor Brown-Séquard, has recently been made a *chevalier* of the Legion of Honour. Upon the same day Professor Ball, another physician of English origin, also received the red ribbon. The *Journal Officiel* sets forth that the reward has been given in both cases for exceptional services, but it is generally thought that the authorities have been exceptionally late in recognising their value.

The annual meeting of the Academy of Medicine took place yesterday, when the perpetual secretary, M. Béclard, pronounced a panegyric upon Andral. The proceedings terminated by the publication of the names of the laureates, prizemen, and medal lists for the preceding year. It is worthy of note that many of the prizes, which are often of considerable value, were not awarded, in consequence of there being no competitors.

M. Marey has been making some observations with the pneumograph, upon the effect of training, which are worth relating. In the state of repose the respiratory curve has a certain amplitude, which in a raw recruit is increased by exercise. After a month's training the respiration in repose acquires an amplitude which it formerly only presented after a long run. After six months the curve is four times as full, but the rhythm only half as quick, and these are no longer modified by exercise, but remain the same even when the soldier, burthened with his knapsack, is made to go through some very arduous drill.

A special grant of 50,000 francs has been made to M. Pasteur by the Chamber of Deputies, to enable him to continue, at the laboratory of the École Normale, his researches upon the contagious diseases of animals. It is anticipated that some very important results will shortly be made known.

July 21th, 1880.

Obituary.

PROFESSOR PAUL BROCA.

THE following biographical sketch of Broca has been forwarded to us by Professor B. Ball, one of his friends and pupils:—

A great existence has passed away. Paul Broca suddenly expired on Thursday, the 8th inst., at midnight. The surprise and deep regret which this unexpected event created, not only in the medical but in the general public, can only be appreciated by those who knew how deep an influence the celebrated Professor had obtained over the minds of those who in France lead an intellectual life.

Broca was born in 1824 at Sainte-Foy (Gironde). His friend, the illustrious naturalist Gratiolet, was born in the same place ten years before, so that by a singular coincidence the two men whose labours (in France at least) have chiefly contributed to our knowledge of the anatomy and physiology of the brain, sprang from the same soil, and were undoubtedly children of the same race. That race, with all its characteristics, its brilliancy, its many-sided capacities, its mental and physical activity, found its fit and proper representative in Broca. He was most emphatically what is termed in Northern France a "*Méridional*,"—a man of the South. The defects of the type, its occasionally unpleasant peculiarities, had totally disappeared in Broca. He retained, however, the extraordinary activity which is the leading feature of the Southern Frenchman, and which, in his case, was most undoubtedly the ruling impulse.

The son of a physician, Broca, at the age of sixteen, had concluded his collegiate studies: he came at once to Paris, where he immediately embraced that course of labour which during forty years he pursued without a moment's interruption, till the hand of death was laid upon him.

Although surgery was at the beginning the object which he seemed to have chosen, anatomy may be said to have been the Alpha and Omega of his intellectual career. In 1846 he became prosector of the Faculty, and gained in rapid succession the honours of the profession—a place as surgeon in the Paris hospitals, and the title of *agrégé* at the Medical Faculty. In 1866 he became a member of the Academy of Medicine, and shortly afterwards (in 1867) was promoted to a chair at the Faculty, where, as a teacher of

clinical surgery, he was highly successful. But the mere enumeration of his scientific dignities would convey an inadequate notion of the man, of his moral type, and of his intellectual powers.

The mental activity of most men is circumscribed by nature within narrow limits. Those who at an early age have begun a severe course of cerebral exertion, although in later years they may retain that soundness of judgment which is the true characteristic of superior minds, are seldom able towards the decline of life to labour as they did in the springtide of their youthful energy. Nature in this respect was liberal to Broca, and during the unusually long space of time which he was allowed to devote to the cultivation of science, he issued a succession of original papers upon the most different subjects, the number of which is almost incredible, and upon each of these he put the mark of a master mind. Some of his works have become classical, and amongst them we must be content to quote his book on Aneurism, his treatise on Tumours, and his memoirs on Diseases of Cartilage, on Rickets, on Vertebral Arthritis, on Strangulated Hernia, on the Surgical Applications of the Galvanic Cautery, &c. Fertility and originality were, in fact, the most prominent features of Broca's intellect, and not one of his productions can be charged with insignificance or mediocrity, nor with that ponderous erudition which laboriously evolves new books out of old ones. His learning was most extensive, but he bore lightly the weight; it never crushed his own independent powers of thought.

But although his clinical teaching and practice were entirely devoted to surgery, his powers of observation enabled him to make one of the leading discoveries in cerebral physiology—to wit, the connexion of that singular mental disturbance described under the name of aphasia, with injuries affecting that limited point of the cerebral surface which is now universally known as Broca's convolution. The most striking point which results from his researches is that the *left* side of the brain seems exclusively to possess (speaking in a general sense) that functional power the loss of which is indicated by the suppression of language—a fact of momentous importance, the consequences of which are too well known to require any comment here. The researches of later physiologists upon cerebral localisations have undoubtedly started from these primordial data; and whatever may be thought of the exaggeration to which the doctrine has been pushed by systematic minds, the fact established by Broca has long since taken its rank among the indisputable truths of science.

The natural bent of Broca's mind received an additional impulse by the foundation (in 1860) of the Anthropological Society, in which he met his old friend Gratiolet. From that moment the activity of Broca's intellect seemed to have found its proper channel. Anthropology is a compound of so many other sciences, in which anatomy, natural history, ethnology, archaeology, and philology take an equal part, that the intervention of a grasping and encyclopædic mind, like Broca's, is almost invaluable to form the connecting link between so many different branches of human knowledge, which at first sight would seem to lie widely apart. An excellent mathematician, a first-rate anatomist, a good Greek scholar, Broca combined in himself that diversified knowledge which the subject requires, with the synthetical tendencies which condense these disseminated forces and make them converge upon a single point. As Secretary-General of the Anthropological Society his services may truly be said to have been invaluable; he was indisputably the right man in the right place.

The excitement, irritability, and fatigue which almost invariably result from severe and protracted brain-work have spoiled many a man's temper, and made him as repulsive to those who live near him as he is attractive to those who see him only from a distance. The cheerfulness, good-nature, and benevolence of Broca were proverbial, and the man who night after night sat up to carry out the labours of the day, was always prepared to join in pleasant intercourse, and the brilliancy of his wit made his conversation as pleasant as it was profitable.

But a higher feeling than mere benevolence was the ruling passion of his moral nature. In all things he aimed at justice, and the claims of friendship were, it might almost be said, sternly put aside when they clashed with his notions of right. On the numerous occasions in which he was called upon to exert his professional influence he never allowed his personal interest or private affections to interfere

with his judgment—a golden rule, but one which it is often difficult to carry out in practice. In short, Broca was an upright judge, and his reputation as such was so thoroughly established that no one ever attempted to exert an unfair pressure upon his conscience.

Like many other independent and earnest men, Broca, from his earliest youth, had belonged to the Republican party; but devoting his entire energy to scientific pursuits, he had never taken an active part in political struggles, when his friends cast their eyes upon him for a seat in the Senate. His election was a signal triumph for the profession, of which he was so eminent an advocate, and his thorough knowledge of all subjects connected with the higher branches of public education would no doubt have made him an invaluable acquisition to the French legislative assembly, if his career, after reaching its culminating point, had not been suddenly cut short. On Tuesday, the 6th inst., he fainted in the Senate House; on the ensuing Wednesday he felt sufficiently recovered to resume his labours; but towards midnight on Thursday he was suddenly seized with a fit of dyspnoea, rose from his bed, and expired in ten minutes. Strange to say, the post-mortem examination gave no clue to the mystery of his unexpected death, all the organs being apparently sound. We shall probably not be far from the truth in attributing the catastrophe to cerebral exhaustion, arising from too protracted a course of severe intellectual exertion.

At the banquet which his friends offered him on the occasion of his election to the senatorial dignity, Broca observed, in returning thanks, that if he believed in ancient superstitions he ought to expect some great misfortune as the penalty for too complete and long-continued prosperity. That misfortune came in the form of sudden death; but in the very bitterness of their grief his friends can scarcely regret that he should have been spared the protracted sufferings of chronic disease, and that he should have disappeared from sight in the fulness of his glory.

STEPHEN H. WARD, M.D.

DR. STEPHEN H. WARD, who died at his residence, 28, Finsbury-circus, of disease of the heart and liver, on the 10th of this month, first commenced practice as a general practitioner. He afterwards became a member of the Royal College of Physicians, and was shortly after appointed Physician to the Dreadnought Seamen's Hospital. In 1870 he was elected a Fellow of the Royal College of Physicians, and in 1872 he published a monograph on some affections of the liver and intestinal canal, with remarks on ague and its sequelæ, scurvy, purpura, &c. He was also for several years Physician to the Hospital for Diseases of the Chest, Victoria Park, and held that appointment at the time of his death.

Dr. Ward was an able and accomplished physician, and was greatly esteemed, and will be much regretted, by a large circle of friends.

MEDICAL NOTES IN PARLIAMENT.

In the House of Lords on Tuesday the County Court Jurisdiction in Lunacy (Ireland) Bill was read a second time.

In the House of Commons on Thursday, 15th inst., the second reading of the Vaccination Acts Amendment Bill was again deferred—this time to Monday, the 26th. A petition against the Bill was presented from Greenwich Union. The completion of the appointment of the Select Committee on the Contagious Diseases Acts was reached at two o'clock in the morning, when Mr. Childers moved, and it was agreed, to add Mr. Massey to the Committee in place of Mr. Brassey. The War Secretary stated that he would have been glad to add Dr. Farquharson, whose name had been put upon the paper by Mr. Puleston, but that he was unable further to extend the number of the Committee.

On Friday, Mr. Sexton called attention to Dr. Woodhouse's report on the fever districts in county Mayo, and specially referred to the statement that the people were predisposed to fever by scanty food, and want of variety in food, their principal means of subsistence for the past eight months having been Indian meal. Mr. Forster replied that he was doing all he could to improve that state of things,

but he would postpone a detailed answer until Monday. Mr. Labouchere asked the Secretary of State for the Home Department, whether he had received a complaint from the solicitors of a Mrs. Hughes that her daughter, Mary Ann Tooke, an inmate for the last six years at the Colney Hatch Lunatic Asylum, had, whilst under restraint in the asylum, been delivered of a male child. Whether he had made any inquiries to satisfy himself that the statement was true. Whether from such inquiries he had reason to believe that not only Mary Ann Tooke, but some other female lunatic, an inmate of the asylum, has been recently delivered of a child. Whether he intended to take any, and, if so, what proceedings, by indictment or otherwise, for the punishment of the guilty persons, and for the protection of the other female lunatics from outrages leading to similar consequences. And whether he would lay upon the table all correspondence between the solicitors of Mrs. Hughes, Mrs. Hughes, the authorities of the Colney Hatch Asylum, and his own Department, upon the subject. Mr. A. Peel replied: In answer to the hon. gentleman, I have to say a complaint was received by the Secretary of State for the Home Department of the nature indicated in the question, and an official inquiry was immediately ordered, and a report made by two Commissioners in Lunacy. Unhappily there is too much truth in the statement which is made in the question, although I am happy to say there is no reason to think other cases of a similar nature have occurred in Colney Hatch Asylum. The facts are now under consideration by my right hon. friend, with a view to further proceedings, and I think the hon. gentleman will see it is not desirable at the present state of the case to furnish the correspondence, but the Home Secretary will be happy to confer with the hon. member on what is admitted to be a very serious matter.

On Monday, a petition was presented from medical officers of the Baltinglass Union, for an alteration of the Irish Poor-law and Medical Charities Act. Petitions against the Vaccination Acts Amendment Bill were presented from the Manchester Medico-Ethical Association and the Council of the West Somerset Branch of the British Medical Association.—Notice was given of the following questions for Thursday: Mr. Watkin Williams, to ask the Secretary to the Local Government Board, whether any regulations exist defining the duties of relieving officers and medical officers of Poor-law Unions in relation to orders for the supply of medical necessities to the sick poor; and whether it is competent to relieving officers to disregard or over-rule at their discretion the orders of the medical officers; and, if so, whether the Local Government Board will consider the propriety of altering the regulations in question. Mr. O'Connor Power, to ask the Chief Secretary to the Lord-Lieutenant of Ireland, if his attention has been called to the Report of Dr. Sigerson and Dr. Kenny on the fever-stricken districts of Mayo, presented to the Mansion House Relief Committee, and to their suggestions for checking the progress of the fever; and, if so, whether he will take steps to have those suggestions acted upon. Mr. Macdonald, to ask the Secretary of State for the Home Department if his attention has been called to an inquest held on Wednesday, the 14th inst., at the White Horse Tavern, St. Matthew's, touching the death of a youth named William Ball. If it be correct that he died from the effects of poison inhaled when following his employment as a copper bronze printer. Whether there be any provisions in the Factory and Workshops Act to prevent youths from being employed in such an atmosphere as will cause the death of those that may be employed where such work is carried on. And, if there be no provision now in existence, will he cause the suggestions made by Dr. Tidy to be carried out, which are as follows: "The free use of milk or other albuminous fluid by the workpeople employed; the wearing whilst engaged at the work a cotton-wool respirator of sufficient size to cover efficiently both mouth and nostrils; that the bronzing should be carried out in a separate compartment or room, and not in the general workshop, in order as far as practicable to limit the evil; that a dress of glazed calico or like material tied round the neck and waist should be worn by those engaged at the work, and that this dress should be removed before leaving the compartment where the process is conducted; that strict cleanliness should be enforced."—Sir S. Northcote inquired whether the Government would insert some provision in the Supplementary Budget Bill to prevent the use of deleterious materials in brewing. Mr. Gladstone replied, that he thought the Adulteration Acts

afforded ample security against the use of injurious ingredients. If damaged grain were used the beer would lose its value, and therefore they must rely on the self-interest of brewers to guard the public from that danger. Sir W. Harcourt stated to Mr. Wodehouse that arrangements had been made for the independent inspection of convict prisons; and, in answer to Mr. Storer, defended the recent decision of the Bedale (Yorkshire) magistrates, by which the Duke of Leeds' steward and other persons were fined £9 in the aggregate, for cruelty in ear-marking cattle. Amongst the witnesses was Professor Ritchie, of the Royal Veterinary College of London, who considered that cutting or slitting the ears of animals was a most cruel custom, causing great pain, and sometimes leaving festering wounds, which remained unhealed for some time. In the present case it was proved that the sores were open for several days; and the magistrates considered the practice was unnecessary, as cattle might be marked in other ways. Mr. Storer said the decision was alarming to agriculturists who had been in the habit from time immemorial of ear-marking cattle. It also affected masters of hounds, who had been accustomed to mark their hounds in the same manner. He gave notice that he would call the attention of the House to the subject. Mr. Forster, replying to two or three Irish members, said the accounts from the fever districts were encouraging, and, considering the bad sanitary state of the places affected, which might justly be described as fever-beds, he was surprised that the disease had not spread more readily.—Lord R. Churchill inquired whether Mr. Dodson's loss of his seat for Chester would involve the withdrawal of the Vaccination Acts Amendment Bill. Mr. Gladstone replied, amidst cheers and laughter, that he had not given much attention to the Bill, but he would consult with the gentleman—presumably the unfortunate Mr. Dodson—who is responsible for it.

On Thursday, Mr. Forster stated that the latest reports of fever in Ireland showed that it was abating, and the local authorities were doing what they could to improve the condition of the cabins.—Mr. Childers said he would give the question of compensation for injuries on torpedo service his best consideration, but it raised some questions of serious importance.—The other two questions of which notice had been given for to-day were postponed.—In the course of the debate on the report of amendments to the Disturbance Bill, Mr. Mitchell Henry stated that a large number of people on the West coast of Ireland were subsisting on food that was hardly good enough for dogs. They had nothing for two or three months in the year but wheeks and seaweed, sprinkled with a little Indian meal.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 19th inst.:

Ashdown, G. W. Whetton, M.B. Edin., Ramsay, Isle of Man.
Bentham, Newton, L.S.A., Hackney.
Bendall, Howard, M.B. Edin., Perth.
Bott, Henry Septimus, L.S.A., Bury, Lancashire.
Brown, Charles, Dudley.
Chadwick, Wm. Fitton, Royton, Lancashire.
Cohen, Algernon Aaron, M.B. Aberd., New South Wales.
Colbourn, Thomas Walter, Woodsetton, near Ludlow.
Hall, Thomas Lambert, L.S.A., Ashford, near Ludlow.
Johnston, Edward Cocks, Birmingham.
Jones, Griffith Job, L.R.C.P. Edin., Liverpool.
Pickersgill, Edwin Puleine, Leeds.
Routh, A. J. McConnel, L.S.A., Montagu-square.
Spencer, Bertram, M.B. Toronto, Toronto.
Thomson, Arthur, M.B. Edin., Edinburgh.

The following gentlemen were admitted Members on the 20th inst.:

Bredin, Richard, Liverpool.
Carter, Godfrey, Leeds.
Dexter, William Parker, Clifton, Bristol.
Fraser, James William, M.B. Edin., Hull.
Godson, Edwin, Chipping Campden.
Harris, David, Leeds.
Maigne, Robert, Salford.
Maish, T. A. Perry, Bristol.
Moore, Stephen Henry, L.R.C.P. Edin., Peckham.
Morgan, Charles Jeffrey, L.R.C.P. Edin., Barnsbury-park.
Neatby, Edwin Awdas, Barnsley, Yorks.
Pope, William Wippell, L.R.C.P. Edin., Exeter.
Roocroft, William Mitchell, Wigan.

Searancke, Nicoll Frederick, Rhyl, North Wales.
Shettle, Harry Wynter, L.R.C.P. Edin., Wimborne.
Thomas, David John, Rhyl, North Wales.
Twynam, George Edward, Blandford-square.
Wills, J. P. Budgett, M.B. Durham, St. Mary's-terrace.
Wilson, John, L.R.C.P. Lond., Wrexham, North Wales.
Winstanley, Robert Wyndham, Crowborough, Sussex.

The following gentlemen were admitted Members on the 21st inst. :—

Barron, Alexander, Southport.
Barrow, Roger William, Liverpool.
Bull, G. G. Robins, Stafford.
Crane, Charles Robinson, Guildford.
Donovan, D. William, Caledonian-road.
Garey, John, Glasgow.
Honeyburne, Richard, Liverpool.
Hutchinson, Jonathan, Cavendish-square.
Laxton, Thomas Lowe, Bedford.
Nodding, Thomas Edward, Trinidad, West Indies.
Parke, Charles James, L.S.A., Hougham.
Parker, C. Barnsdall, M.D. Ohio, Cleveland, Ohio.
Payne, A. Bruce, Deal.
Proffitt, A. Henry, Rugeley.
Potts, J. Ashford, M.B. Edin., Broseley.
Renshaw, Israel J. E., Sale, Cheshire.
Stoneham, Thomas George, Rye, Sussex.
Wagstaff, E. Hamilton, Leighton Buzzard.
Wolstenholme, R. Hanson, Manchester.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 15th inst. :—

John F. Molineux and William J. Murray, Charing-cross Hospital;
Arthur N. Clarke, St. Bartholomew's Hospital; Henry J. Pringley,
St. Thomas's Hospital; Herber H. Williamson and Frederick E.
Pearse, University College; Ernest W. Benson and Sidney E.
Craddock, King's College; John J. D. Vernon, Manchester; and
James J. Prendergast, Melbourne and Guy's Hospital.

Of the 192 candidates examined during the past fortnight, 78 failed to satisfy the Board, and were referred for three and 12 candidates for six months' further anatomical and physiological study.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on July 15th :—

Benoly, Nathaniel, Grove-road, Victoria-park.
Bray, Ernest Edward, Darlington, Bognor.
Campe, Charles Frederick, Stratford, Essex.
Foster, William, Horton-lane, Bradford.
Holton, Francis Wm. Parke, York-crescent, Woolwich.

The following gentlemen also on the same day passed their Primary Professional Examination :—

John Chas. Davies, London Hospital; George Francis Symons, Guy's Hospital; Henry Gervase Watson, Sheffield School of Medicine.

The Library of the Obstetrical Society will be closed during the month of August.

DR. J. H. GLADSTONE has presented £100 to the Research Fund of the Chemical Society.

A TENDER has been accepted for the erection of an abattoir in Dublin, at an estimated cost of £13,135.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The foundation-stone of a new wing to this hospital was laid on Wednesday by the Duke of Westminster. The wing will add eighteen beds to the 110 formerly provided in the institution, besides supplying a complete out-patients' department. The cost of the addition is estimated at £9000, of which £6300 has been subscribed.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the annual meeting held on the 13th instant, the following officers were elected for the year ensuing :—President: Dr. J. S. Bristowe. Vice-Presidents: Dr. G. Buchanan, Dr. Thomas Stevenson, Dr. C. O. Baylis, Dr. W. H. Corfield. Treasurer: Dr. J. W. Tripe. Secretaries: Dr. J. N. Vinen, Mr. S. F. Murphy. Council: Dr. G. P. Bate, Dr. A. T. Brett, Mr. F. M. Corner, Dr. J. Dixon, Dr. T. O. Duffield, Dr. A. Hill, Mr. E. L. Jacob, Mr. S. R. Lovett, Dr. E. C. Seaton, Dr. J. Stevenson, Dr. R. P. B. Taaffe, Dr. J. F. W. Tatham.

THE FACTORY AND WORKSHOP ACT.—The Home Secretary, under the provisions of sections 43 of the Factory and Workshop Act, 1878, has granted to workrooms in connexion with drapers' retail establishments, and to workshops in which the curing of fish is carried on, a special exception "that the period of employment for young persons and women, if so fixed by the occupier and specified in the notice, may, except on Saturday, begin at 9 a.m. and end at 9 p.m., and in such case the period of employment for a child in a morning set is to begin at 9 a.m., and the period of employment for a child in the afternoon set is to end at 8 p.m."

EARLSWOOD IDIOT ASYLUM.—The usual annual festival of this useful institution was held last week, and passed off with its wonted *éclat*. Dr. Grabham, the superintendent, reports that during the year ending in March there was a fair proportion of improved cases among the inmates, while two were stated to be cured. The death-rate was 4.4 per cent. calculated on the total number treated. It is satisfactory to learn that the asylum is out of debt, but a sum of £300 is required to complete the infirmary.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The directors of this society held their usual quarterly Court on the 14th inst., the President, Sir George Burrows, Bart., in the chair. Fresh applications were made from one widow and three orphans, and relief granted to them. The amount to be distributed for the half-year among the sixty widows and sixteen orphans now on the list of recipients was £1317 10s. The expenses of the quarter amounted to £44 9s. Only one new member was elected. The directors take this opportunity of announcing that, under the new bye-law, all registered medical practitioners living within a radius of twenty miles from Charing-cross are eligible for election as members.

THE PARKES MUSEUM OF HYGIENE.—The first annual public meeting of the Parkes Museum is to be held on Tuesday, the 27th inst., at 3 P.M., in the Egyptian Hall of the Mansion House, under the presidency of the Lord Mayor. We understand that the Executive Committee are finding the present rooms occupied by the museum hardly equal to its requirements, and that an effort is to be made to establish the collection in some central position, and one more accessible than that which it at present occupies. Many persons of eminence in political and social circles have promised to attend, and we doubt not that those City companies which have proved already that technical education is a matter dear to them, will be represented on the occasion, and will tender a generous support to an institution which has already done good work in spreading a knowledge of sanitary technology among the artisan and other sections of the public.

ARMY MEDICAL SCHOOL ATHLETIC SPORTS.—An athletic meeting in connexion with the Army Medical School, Netley, was held on Thursday, July 8th, in the presence of a large number of spectators. The events, in most cases, were very closely contested. I. Throwing the cricket-ball (six competed) : 1, J. R. Ronayne, 96 yds.; 2, C. Henderson, 94 yds. II. Hundred yards race (six ran) : 1, A. Peterkin; 2, E. R. Cree. III. Long jump : 1, J. R. Ronayne, 20 ft. 3 in.; 2, W. Heffernan, 19 ft. 7 in. IV. Quarter-mile race (five ran) : 1, A. Peterkin; 2, C. Henderson. V. Hundred yards soldiers' race (six ran) : 1, Blake, A.H.C.; 2, Quibble, A.H.C. VI. Putting the weight (four competed) : 1, A. Peterkin, 32 ft. 7 in. VII. Half-mile race (six ran) : 1, C. Henderson; 2, H. P. Dimmock. VIII. High jump (four competed) : 1, A. Peterkin, 5ft. 1½ in.; 2, C. S. Rundle, 4ft. 10 in. IX. Quarter-mile soldiers' race (five ran) : 1, Quibble, A.H.C.; 2, Warman, A.H.C. X. Tug of war—Indian v. Home Service, ten a-side: The Home Service being considerably heavier than their opponents won somewhat easily. XI. Hurdle race, 120 yds., over ten flights : 1, A. Peterkin; 2, W. Heffernan. XII. One mile race (five ran) : 1, C. Woods; 2, H. P. Dimmock. XIII. Consolation race, 200 yds. (four ran) : 1, M. W. Kerin; 2, J. H. Harran.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ANDERSON, R. B., F.R.C.S.E., has been appointed Public Medical Officer of Tobago.
BAKER, Mr. J. B., has been appointed Assistant Surgical Officer to Charing-cross Hospital.
BENNETT, W. H., F.R.C.S.E., has been appointed Assistant-Surgeon to St. George's Hospital, vice Stirling, resigned.
BOND, J. W., M.B., has been appointed Resident Medical Officer to University College Hospital.
CLARKE, W. J., L.S.A.L., has been appointed Assistant Medical Officer to Charing-cross Hospital.
CORRY, H., A.B., M.D., M.Ch., has been appointed Assistant-Surgeon to the North Charitable Infirmary, Cork, vice O'Sullivan.
FAIRLAND, Mr. S. T., has been elected Medical Officer and Public Vaccinator of the Fovant District of the Wilton Union.

FARRANT, S., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer to the Taunton Sanitary Hospital.

FOLEY, S., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the St. David's District of the Haverfordwest Union.

FOTHERGILL, E., L.D.S., has been appointed Dental Surgeon to the Newcastle-on-Tyne Infirmary.

FOY, F., M.R.C.S.E., has been appointed Dental Surgeon to the Infant Orphan Asylum, Wanstead, and to the Royal Hospital for Incurables, Putney, vice Tracey, resigned.

GOYDER, C. M., L.R.C.P.Ed., M.R.C.S.E., has been appointed Senior House-Surgeon to the Newcastle-on-Tyne Infirmary, vice Dixon, resigned.

HEWETT, F. C. C., M.R.C.S.E., L.S.A.L., has been appointed Assistant Medical Officer and Dispenser to the Cleveland-street Sick Asylum, vice Hopkins, resigned.

HILL, A. B., M.D., has been appointed Public Analyst for the Borough of Leamington for one year.

LLOYD, D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Kenarth District and the Workhouse of the Newcastle-on-Emlyn Union, vice Thomas, resigned.

MILBURN, F. Le F., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fourth District of the Holborn Union, vice Betts, resigned.

O'SULLIVAN, S., M.D., M.Ch., has been appointed Surgeon to the North Charitable Infirmary, Cork.

PEARSE, T. F., M.D., has been appointed Medical Officer and Public Vaccinator to the Bramsholt District of the Petersfield Union.

POWELL, H. A., M.A., M.R.C.S.E., L.R.C.P.Ed., L.M., L.S.A.L., has been appointed Resident House-Surgeon to the Western General Dispensary, Marylebone-road, vice J. E. Bullock, M.D., resigned.

STODDART, Mr. F. W., has been appointed Public Analyst for the City of Bristol, vice W. W. Stoddart, deceased.

SWEETING, R. D. R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Fulham Small-pox Hospital.

TREVES, F., F.R.C.S.E., has been appointed Senior Demonstrator of Anatomy at the London Hospital Medical College, vice Dr. H. S. Wilson, resigned.

WALKER, W., L.S.A.L., has been appointed Resident Obstetrical Officer to Charing-cross Hospital.

WATSON, F. S., M.R.C.S.E., has been appointed Resident Surgical Officer to Charing-cross Hospital.

WILLIAMS, J., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Workhouse of the Brecknock Union, vice J. C. North, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ANDREWS.—On the 15th inst., at Everleigh, Green-hill, Hampstead, the wife of James Andrews, M.D., of a daughter.

DEAKIN.—On the 4th inst., at Eastbury Manor, Worcester, the wife of Surgeon C. W. Shirley Deakin, F.R.C.S.E., H.M.'s Bengal Army, of a daughter.

EDIS.—On the 13th inst., at 22, Wimpole-street, the wife of Arthur W. Edis, M.D., F.R.C.P., of twins (both girls).

FRANKLIN.—On the 14th inst., at Welford-manor, Leicester, the wife of G. C. Franklin, F.R.C.S.E., of a son.

HOPKINS.—On the 19th inst., at 4, Gay-street, Bath, the wife of H. Culford Hopkins, M.R.C.S.E. &c., of a son.

HOPWOOD.—On the 14th inst., at Exeter, the wife of Surgeon-Major Hopwood, of a daughter.

LEWIS.—On the 16th inst., at Albert-street, Regent's-park, the wife of Louis Lewis, M.D., of a son.

MEREDITH.—On the 14th inst., at Week-street, Maidstone, the wife of John E. Meredith, M.D., of a daughter.

THURSFIELD.—On the 11th inst., at High-street, Bridgnorth, the wife of William Thursfield, M.D., of a son.

MARRIAGES.

ADAMS—SCHOLFIELD.—On the 17th inst., at St. Helen's Church, Bishopsgate, London, James E. Adams, F.R.C.S., to Ellen Holgate, third daughter of the late John Scholfield, Esq., of Faxfleet Hall, Howden, Yorkshire.

KAY—FOWLER.—On the 17th inst., Alfred Kay, L.R.C.P., of Green-street, Victoria-park, E., to Emily, younger daughter of the late Stephen Marshall Fowler, Esq., of Ranby-hill, Wragby, Lincolnshire.

WALKER—ORIEL.—On the 15th inst., at St. Mary's, West Kensington, Horace Walker, L.R.C.P.L., of The Cedars, West Kensington, to Maria Louisa, third daughter of the late Dr. Oriel, of Alfred-place, W.C., and of Mrs. Oriel, of Elms House, West Kensington.

DEATHS.

FORSYTH.—On the 30th May, at Laura, South Australia, Alexander Forsyth, M.D., aged 30.

THOMAS.—On the 16th inst., at Wells-street, W., Edward Stevenson Thomas, M.R.C.S.E., aged 47.

THOMPSON.—On the 13th inst., at Manningtree, Essex, Anne, relict of William Thompson, M.R.C.S.E. (late of Manningtree), in her 90th year.

WILSON.—On the 8th inst., at Aberdour House, Fife, N.B., Sarah Liddell, wife of Robert Wilson, M.D., and daughter of the late John Liddell, Esq., of Manchester-square, London.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

AN EPIDEMIC OF DEMONOMANIA.

OUTBREAKS of demonomania are so rare in the present age that the subject has almost fallen outside the consideration of writers on public health. We note with considerable interest an account of an epidemic of demonomania reported by Professor Léon Collin in the last (July) number of the *Annales d'Hygiène Publique*. The epidemic occurred in an isolated, remote spot of the district of Tolmezzo, Udine, Northern Italy, at the beginning of 1878, and the characteristics of the outbreak of earlier period were repeated in every respect. The starting-point was a case of simple hysteria in a female, dealt with by ignorant priests as a case of "demoniacal possession," and in the end, 18 cases, 15 of ages varying from 16 to 26 years, and 3 of the respective ages of 45, 55, and 63 years, were cultivated. The intervention of the authorities and of a proper medical staff, when the news of the outbreak reached Udine, quickly put a stop to the extension of the malady, and brought it to an end.

THE MEDICAL BENEVOLENT COLLEGE.

To the Editor of THE LANCET.

SIR,—We shall be much obliged if you will spare us space for a short explanation of the present position of a subscription which was inaugurated by the late Dr. William Carr shortly before his death, with the object of having a portrait of Mr. Erasmus Wilson painted and placed in the Royal Medical Benevolent College at Epsom, which owes so much to his liberality. The amount subscribed proved to be insufficient for the object proposed, and, in the uncertainty what to do with it, the money has remained in our hands, as joint treasurers with the late Dr. Carr.

Having ascertained that Mr. Wilson, to whom it was intended to do honour, would much prefer the appropriation of the fund to a prize of some kind for the benefit of the Epsom boys, rather than to a portrait of himself, the amount now in hand (£65) has been invested in Consols in the names of trustees, with a view to the foundation at some future period of a prize bearing his name at the College.

We are, Sir, your obedient servants,

GEO. C. JONSON.

J. LUMSDEN PROPERT.

Soho-square, July 12th, 1880.

CYPRUS.

DRS. G. C. SCHIRAS and E. L. GILIZIAS, says the *Chemists' Journal*, have recently reported very favourably on Cyprus as a drug-producing island. They state that nearly all the aromatic herbs and medicinal plants thrive well; that mint, rosemary, lavender, &c., attain great perfection, yielding essential oils second in quality to none imported into this country.

Mr. G. Buckston Browne.—Our space will not allow of the publication of any further correspondence on the subject.

RESTORATION OF THE HAND AFTER COMPLETE SEPARATION FROM THE ARM.

DR. L. L. STATON, of Tarboro, N.C., relates, in the *North Carolina Medical Journal*, a case in which a useful hand was preserved after separation from the arm, excepting a small portion of skin, below the articulation with the ulna. The injury was accidentally effected by an axe, by which the limb was severed from the styloid process diagonally across the trapezium, dividing all the muscles, bones, and bloodvessels. After an unavoidable delay of nearly an hour, Dr. Staton proceeded to replace the hand, which was held securely in position with silver sutures and adhesive plaster, and bound, together with the arm, on a broad splint. On the third day pulsation could plainly be felt in the hand. The sutures were removed on the fourteenth day. Finally, the patient was able to extend the fingers of the wounded limb, and to grasp with nearly her wonted strength.

Mr. Hugh Adcock.—Our correspondent's view of the facts is the right one; but the letter of Mr. Howell contains such a proper expression of regret, with explanation, that we do not see the necessity to publish the correspondence.

L. A. X.—For South Australia. 8, Victoria-chambers, Westminster, S.W.

TREATMENT OF SCALP WOUNDS.

To the Editor of THE LANCET.

SIR,—In the "Mirror of Hospital Practice" Mr. Spencer Watson records a case of severe scalp wound, with very rapid recovery, which he attributes partly to the *antiseptic dressings used*; but he does not tell us how long the poultices ordered Feb. 10th were continued, or what the antiseptic dressings were. Was the application of *carbolic oil* [the antiseptic treatment?—and is it not probable that the poultices were more concerned in the favourable issue? Such, at least, my experience of three or four similar cases at the West London Hospital would lead me to believe; and I think that in severe cases of scalp wound, especially where bone is exposed and the covering torn away, we have no agent so powerful as good hot poultices to induce the growth of granulations and obviate the swelling of surrounding parts, which most certainly you will get if the wound does not heal at once. So satisfactory have I found this treatment, that now I never hesitate to order poultices in severe scalp wounds, and even in ordinary ones if closure by first intention is not effected.

I have no experience of the treatment of scalp wounds under a rigid Listerian method, and I should like to have the opinion of some of your readers upon the subject of the treatment of scalp wounds where thorough antiseptic precautions are impossible.

I remain, Sir, yours faithfully,

Torquay, July, 1880. G. W. HAMILTON CUMMING.

SCURF AFTER RINGWORM.

MR. ALDER SMITH, the resident medical officer, Christ's Hospital, London, writes:—"With regard to scurf patches left after inveterate ringworm of the scalp, I would advise your correspondent to examine the scalp very carefully with a lens to see if there are not one or two short stumps to be seen, or a few black dots. I usually find the scurf patches disappear when the disease is absolutely well, especially if glycerine with a small quantity of carbolic acid be used. Citrine ointment, diluted with seven parts of lard, is the best application I know of to remove any scurf spot that is left."

MR. G. M. A. RUDKIN, of Teignmouth, observes:—"If your correspondent 'M.D.' will use a lotion made of equal parts of carbolic acid and glycerine, to be well rubbed into the affected spots every night, he will find the scurf to have entirely and permanently disappeared in the course of two or three weeks. I have used the above in most inveterate cases, and have never found it to fail."

DR. W. H. LAMBART, of Liverpool, states:—"The following has proved so successful in my practice that I would, with confidence, recommend it to your correspondent 'M.D.'—Nitric oxide of mercury ointment, benzoic ointment, of each half an ounce; rub in a little night and morning, at the same time give the following:—Sulphate of quinine, twenty grains; dilute nitric acid, one drachm; tincture of oranges and tincture of calumba, of each one drachm and a half; simple syrup, 1½ an ounce; water to eight ounces: one tablespoonful three times daily, twenty minutes before meals."

MR. JAS. STARTIN, of Sackville-street, writes:—"Your correspondent M.D., calls attention to a by no means unimportant element in the treatment of ringworm, and one which is often overlooked, that of obstinate dandruff remaining behind, the true disease being to all appearance cured. A little vaseline, with three or four grains of nitric oxide of mercury to the ounce, and five minims of creasote, well rubbed into the skin, after washing, night and morning, I think he will find the most effectual remedy."

Therapeutist.—An experiment with the *Cynoglossum officinale* as a remedy in hydrophobia has, we believe, been made at the Hospital for Incurables, Naples. Some amelioration in the symptoms was effected, but the patient died.

Mr. Leeming (Kendal).—We have no recollection of the paper.

TREATMENT OF HÆMORRHOIDS BY "CRUSHING."

To the Editor of THE LANCET.

SIR,—As inventor of the clamp for the treatment of hæmorrhoids by crushing under Mr. Pollock's theory, I trust you will permit me to offer a few remarks in your valuable columns by way of reply to the letter of your correspondent Mr. Barrow, inserted in your number of the 10th instant.

As I consider that Mr. Pollock has not given himself as much credit as he deserves with respect to the operation under his theory, I think I cannot do better than give a brief outline of the four cases which have come under my notice since this clamp has been used.

In the first case there was certainly a slight oozing, which Mr. Pollock arrested by means of three ligatures. This I attribute to the following causes—first, the clamp was not sufficiently screwed up; and secondly, it was removed immediately it was applied, whereas the grasp ought not to have been released, as I shall presently show, for about two minutes. The patient did not complain of the slightest pain, but only of a sensation of sickness due to the effects of the ether, but which soon disappeared, and on the following morning expressed astonishment that he should have been asked if he experienced any pain. I may add that an anodyne was not administered. With a view of satisfying myself that all sensation was absent from the part to which the clamp had been applied, I pierced, three hours after the operation, the thin shred (or fringed remnant) with a needle, but this the patient could not feel!

In the second case, two independent growths were operated on with the clamp. In the first there was a very slight oozing, which was secured by a ligature at the point at which it occurred. In the second there was not the slightest bleeding, and I attribute this to the fact that the clamp was allowed to grasp the pile for about half a minute. This patient, who some years ago received an injury to his coccyx, and from which he has experienced pain more or less ever since, expressed himself as entirely free from pain, as far as the operation was concerned, three hours afterwards.

The third operation was performed in private by Mr. Pollock, who informs me that he allowed the clamp to grasp the pile for about a minute, and that on its being removed there was not the slightest oozing, nor did the patient experience any pain.

The fourth case was also treated in private by Mr. Rouse, who informs me the patient underwent an operation for piles about ten years ago by one of our most eminent and skilful surgeons, and experienced so much pain and inconvenience for some considerable time that she expressed her extreme reluctance to submit to another operation. Mr. Rouse, however, operated on a large internal pile, allowing the clamp to grasp it for about four minutes, and on removing it there was not the slightest oozing. The patient complained merely of a feeling of soreness for a few hours afterwards, which was, no doubt, due to the dragging of the pile with the pronged fork.

It may thus be seen that if the clamp, after being firmly applied, be allowed to grasp the pile for about two minutes, all oozing may be avoided, and even if it should occur (which I feel confident would not be the case), the application of the torsion forceps would sufficiently control any bleeding. When the thin shred (or fringed remnant) which the clamp leaves, and which is extremely dense, and no thicker than a stout piece of paper, drops off, the surface of the part operated on is on the same plane as the surrounding parts (unlike cases where other clamps have been used). In all the cases mentioned by me above, the patients have virtually recovered from the operation as soon as the effects of the ether have disappeared.

Now it is needless, and, perhaps, not within my province, to enter into details with regard to other methods of operating, as, although I have had some acquaintance with them during my course of study, doubtless the great majority of your readers have had more extensive experience on the subject than I have had; but I venture to assert that those who argue that the after-effects of the operation under Mr. Pollock's theory are the same as in other methods, are wrong, as the facts stated by me are incontrovertible; besides, the former is simpler and certainly more scientific, for by means of one crush the whole operation is at an end, whereas by ligature or with other clamps and actual cautery great care and very skilful treatment are absolutely necessary; for if in the former case the mucous membrane be not sufficiently snipped, the patient will experience acute and almost indescribable suffering, many instances of which have come under my notice. The bleeding very often conceals the parts to be snipped before the ligature is applied. I have very frequently noticed that when in cases where the clamp and actual cautery have been used, the heated iron or benzoline cautery were not in working order—a dereliction of duty no doubt on the part of the assistant, but such is the case, occurring more often in private than in hospital practice. I confess, of course, that this is a mere matter of detail, but not to be overlooked.

While dwelling upon this subject, may I be permitted to suggest that in favourable cases, as a substitute for an anæsthetic, the part to be operated on might be frozen by means of the ether spray; for the interval between the application of the clamp and the closing of its jaws is momentary, and all sensation of pain avoided. I make these remarks by way of suggestion, as I have had no practical experience on this point. I may also suggest that it would, perhaps, be better to cut off the pile, while it is in the grasp of the clamp, with an ordinary scalpel instead of with scissors curved on the flat. This, again, is a mere matter of detail.

I am, Sir, your obedient servant,

R. F. BENHAM,

July, 1880.

Ophthalmic Assistant, St. George's Hospital.

NORTH DUBLIN UNION: A CONVALESCENT HOME.

THE Board of this union having advertised for a site for a convalescent home and small-pox hospital, Dr. MacCabe, Local Government Board inspector, has suggested that they should build sheds, and not encumber themselves with any stone building. In every union with which he was acquainted, except the North and South Dublin Unions, they had a fever and small-pox hospital, and a place for the agricultural instruction of children in the same area. He advised the guardians to take a piece of ground not less than twenty acres, and he believed the health of the inmates of the building would deteriorate unless vegetables were grown, and the dietary improved by their use, or a large sum of money expended in their purchase.

Delta.—Our correspondent's letter is too long and too diffuse, and we do not think any good would result from its publication. We have already strongly advocated a revision of the scale of pensions granted to the medical officers of the Indian service.

M.D. Edin.—Yes. The Hearts of Oak Benefit Society, for instance.

THE USE OF THE HOT VAGINAL DOUCHE.

To the Editor of THE LANCET.

SIR,—If Dr. Murray will refer to a paper of mine, on "A new form of Vaginal Douche," which appeared in THE LANCET early in the present year, or write to Maw and Co. for one of the instruments, he will find a very simple but thoroughly efficient remedy for the discomforts he complains of. I used it lately for the application of the hot douche for over two hours, and not a drop of water escaped between the vulva and the tube, the patient lying comfortably on her side and without the slightest exposure the whole of the time. I am about to have it improved by being made entirely of india-rubber; for, although the simple 1½ in. tube answers perfectly as a canal for the entrance and exit of the water, I find that by making it slightly bulbous it is automatically retained, and both hands of the operator are then at liberty, whilst the vulcanic cone is dispensed with—a further advantage; for, by pinching the end of the tube flat between the finger and thumb, it can be slipped into the vagina without the slightest pain to the patient, and any chance of septic matter lodging between it and the cone is avoided.—Yours &c.,

Ixworth, Suffolk, July, 1880. G. F. MASTERMAN, L.K.Q.C.P.

GLANDERS.

A GERMAN military Surgeon, writing to the *Militär-Wochenblatt*, directs attention to the danger arising from the thoughtless use of the pocket-handkerchief in removing foam which may have been cast upon clothes from the mouth or nose of the horse. A case is cited, in which an officer, the owner of a glandered horse that had been shot, was attacked with what at first appeared a catarrh, but which, resisting all the usual remedies, eventually proved fatal. The whole of the circumstances of the case led to the conclusion that the unfortunate gentleman had been guilty of the indiscretion referred to, and thus contracted glanders.

W. G. M.—Two eggs of the Great Auk, discovered in an old private collection in Edinburgh, were sold by Messrs. Stevens on the 2nd inst., and realised £100 and 102 guineas respectively. The College of Surgeons was not so fortunate, when the same auctioneers sold some time ago three for only £90; still retaining, we believe, six of these rare and valuable eggs.

L. M. M.—Flowers at night absorb oxygen and exhale carbonic acid. Therefore they do to a certain extent injure the atmosphere.

Dr. W. Curran's paper shall appear in an early number.

Enemy should consult a qualified medical practitioner, and avoid advertising quacks.

ANIMAL VACCINATION IN HOLLAND.

A CORRESPONDENT send us the following information:—

"An account of animal vaccination in Holland may be interesting, especially at this time when the subject is being brought so prominently before the profession and the public.

"Bull and cow calves are selected about three months old. By means of a contrivance, the animal is fixed on to a table, so that its abdomen is fully exposed. The lower abdomen is then shaved, this part being selected for the vaccination. The lymph is taken from calves vaccinated the previous week, or from sealed tubes. About fifty to seventy punctures are made with an instrument resembling that used for paracentesis corneæ. As soon as the vaccination is finished, the animal is removed to a cow-house. It is fed on ten pints of milk a day. They sometimes have diarrhoea during the maturation of the vesicles, but never have any fever, and often get much stouter. In five or six days the vesicles are ready for use. At Rotterdam the calves are vaccinated on the Wednesday, and the public attend the following Monday at the establishment, and are vaccinated direct from the calves. The whole vesicle is scraped out, the lymph epithelium and other debris being used, as it has been found by experience that the pure lymph is uncertain in its action on the child, although calves are inoculated by it with good effect. If a surgeon wishes to vaccinate anyone away from the establishment, he is obliged to carry the contents of the vesicle between two flat pieces of glass. The lymph must, of course, be used the same day as it is removed from the calf. The calves are returned to the cattle-dealer as soon as they are finished with."

MEDICAL PRACTICE IN TEXAS.

A WRITER in the *Chicago Medical Times* gives a most lugubrious account of medical practice in Texas, to which State he was induced to repair for the benefit of his health. Though "a graduate of one of the first medical universities of the North, with a civil and military medical experience of thirty years," he was compelled to undergo an examination before being allowed to practise. After recounting instances of injustice and loss to which he was subjected, he gives the following as a bit of experience of a brother practitioner in Texas:—

"There recently lived at Round Mount, on account of his health, a plucky old army surgeon, whose personal safety was more than once in jeopardy for his fearlessness as a citizen and as a physician. The doctor was liberal and benevolent to all that needed his services; but his retired and aristocratic status gave the natives offence, and by a process of slow torture, they got rid of him. They stole his property, killed and mutilated his stock, polluted his well, defrauded him of his just claim, and, as the execution of the law was in their own polluted hands, he had no redress for any of these Vandal and Visigothic doings. In one case he attended a woman who passed through a difficult and dangerous labour. By the most consummate skill he saved her life. It happened that the husband had a small claim against the doctor as purchase money—an amount less than the doctor's bill. The man instituted suit against the doctor, and this 'granny bill' became the dirty public property of the courts for two years. The doctor not only lost his fee, but had the costs to pay. One item of this cost was \$25 from a lawyer, who brought suit against the doctor for saying 'I would' to his employed lawyer. It is ridiculous to suppose that such a claim could be established even in the most corrupt of tribunals. Still the case went against the doctor on this unique basis. The court believed the claim a fraud; but, as the account was legally substantiated, the verdict was rendered in favour of the plaintiff. A wealthy cattle man broke his wrist. The doctor treated the case with the pistol-shaped splints. The man took off these splints, and applied lateral pressure, of course with unfavourable results. He not only refused to pay his surgical bill, but assailed the doctor for a fault he committed himself. The doctor brought suit against him; but, as might have been expected, he lost his bill, and gained no credit professionally. Another case: At one time he performed, with fine success, an operation on a child for club-foot, and took a bill of sale for six cows for the operation. When the doctor sent for the cows, the father secretly drove them out of the country beyond the doctor's reach, and, what was most singular, in order to ruin the effects of the operation, the mother took the club-foot shoe from the child's foot."

Dr. Williams.—The Secretary, Mr. Freeman, 37, Soho-square, will doubtless give all information. There are fifty pensioners who receive annuities of twenty guineas each; twenty-four of them have, in addition, furnished rooms in the College at Epsom, and an allowance of three and a half tons of coal each. Their yearly income must not exceed £60.

R. R. H.—The name mentioned is not to be found in the Medical Register.

Dr. J. A. Campbell.—In an early number.

FEES FOR SCHOOL BOARD CERTIFICATES.

To the Editor of THE LANCET.

SIR,—In your issue of to-day you insert an extract from the *Catholic Times* of July 2nd, referring to payment for School Board certificates. In connexion with this, allow me to suggest that a fee should be paid to medical men, who, as frequently occurs in London, are requested to fill up the medical questions on the School Board form for sending a child to an industrial school by order of a magistrate, before whom the child has been brought by the School Board. Underneath the medical certificate are one or two lines for "Remarks," and a medical friend of mine gave vent to his feelings on the matter on which I write by filling up the "Remarks" with these words: "I am of opinion that a fee should be paid for the above."

I enclose my card, and remain yours faithfully,

July 17th, 1880.

A MEDICAL OFFICER.

Dr. Foster, (Leeds).—Several good filters are sold, and we do not care to give the preference to one. No filter will remove all organic matter.

A. H.—Holmes's or Bryant's Surgery; Bellamy's Surgical Anatomy; Billroth's Surgical Pathology.

Dr. Louis Lewinson.—The qualification named is a surgical one only, and does not carry the right of charging for services in medical cases.

Mr. J. H. Durrah.—We think we may safely say the quotation is fabulous.

PHYSICIANS' ATTIRE.

To the Editor of THE LANCET.

SIR,—Many have, doubtless, observed the recent and admirable action of the Mayor of Derby, who, with the consent of the Lord Chancellor, has ordered all solicitors when practising in Court to appear in robes. As then the clergy have a distinctive dress, and the legal profession theirs, would it not be well for the Councils of the several Royal Colleges of Physicians to consider and decide upon a distinctive attire for their fellows and members to appear in on special occasions, and thus to designate the learned profession to which they belong? Hoping that this suggestion will be taken up by others, I am, Sir, yours obediently,

July, 1880.

M.R.C.P. Ed.

ADULTERATED MEDICINES.

DR. C. A. CAMERON, public analyst for the county Monaghan, reported to the recent meeting of the Grand Jury of that county that nine medicines which he had examined for a Poor-law union were all adulterated. "Sulphate of quinine" was composed wholly of an article one-tenth the price of the former—namely, sulphate of chinchonine. The "tinctures" were deficient in spirit (one containing none at all) and other ingredients, and wanting altogether in others. Methylated ether was used in preparing tincture of lobelia.

P. H. R.—We regard the charge as inadequate. It ought to have been twice as much.

H. had better apply to the editor of a sporting paper.

DOG-BITE AND HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—Owing to some remarks upon this subject in a late number of your journal, I venture to make a statement as regards the necessary health of the dog.

A case came under my care some years ago, the notes of which, with post-mortem examination, I gave the late Mr. V. de Méric, and were inserted *verbatim* in a medical paper. The state of the dog may be of interest to some of your non-professional readers. I had the dog brought to me the same afternoon, that I might see his state before he was killed. Having had much experience of dogs in distemper, with snapping and excess of saliva, I wished to see if he was so suffering. This animal was healthy in appearance, lively and attentive, and drank water directly I gave it to him, and during the two or three days I had him in my rooms no dog could have behaved better. He was brought to me by the owner and the mother of the patient.

Bearing upon the subject of the immediate treatment of the bite, it is curious to note that the outer wound had nitrate of silver applied almost immediately; but an inner wound escaped notice, and there the pain began a month after the occurrence, and commenced the illness, from which the patient died in about thirty hours.

I am, Sir, yours faithfully,

Brixton, July 12th, 1880.

WARREN H. DIAMOND.

Medical Diary for the ensuing Week.

Monday, July 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Tuesday, July 27.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

Wednesday, July 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

Thursday, July 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

Friday, July 30.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, July 31.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Clinical Retrospect

OF A

HALF-YEAR'S HOSPITAL WORK.

By MATTHEW CHARTERIS, M.D.,

PROFESSOR OF MATERIA MEDICA AT THE GLASGOW UNIVERSITY, AND
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY.

[In his concluding lecture to his class at Anderson College, Dr. Charteris gave a summary of the work at the Royal Infirmary during the winter session of 1879-80. The accompanying report, as revised by Dr. Charteris, is supplied from the notes taken by Mr. G. W. Till, resident surgeon to the Kidderminster Infirmary.]

Commencing with the subject of fever, Dr. Charteris said he had had one example of simple febricula, in which, after a couple of days of high temperature of 103°, and without any chest complications, a crisis occurred, followed by a copious perspiration and a normal temperature.

One case was admitted simply with fever, frontal headache, and a history of a distinct rigor. The patient, a woman aged thirty, was under observation for two days. The morning and evening temperature was respectively 103° and 103·6°. There was no diarrhoea, no tenderness over the iliac region. Two days after her admission, presumably on the fifth day from the rigor, the characteristic dark-mottled eruption of typhus appeared on the body; and after it had been observed by the clinical clerks and others the patient was removed to Belvedere, and made a good recovery.

Two cases of typhoid fever were treated during the winter, both being males. The characteristic rose-coloured spots were apparent about the tenth day of the fever, lasting for the normal period of three days, to be succeeded by others. The clinical clerk in charge of the case marked them round with ink, so that the class might have an opportunity of observing the features and duration of the eruption. The treatment was based on the pathology of the disease, and consisted of a careful attention to diet. Milk was the only thing given until the temperature became normal in the morning, when it was supplemented by beef-tea and toast and water. The highest temperature marked was 104°. Hobson's charts, lately published, were found very beneficial in giving an accurate estimate of the progress of the fever, and they can be cordially recommended to all hospital physicians. Both cases made a satisfactory recovery.

One case of scarlet fever came under observation. It was admitted as a case of bronchitis, but on the appearance of the eruption on the second day the girl was at once removed to the Fever Hospital, such cases never being retained in our public infirmary.

There were sixteen cases of dropsy, which were classified under cardiac, renal, and hepatic, according to the organ chiefly implicated. Of these, one cardiac case, two hepatic, and one renal, died. The others so far improved as to be able to leave the hospital. Three of the renal cases being, if the expression may be used, cured. One of the renal cases was complicated with renal convulsions, and it was found that the injection of digitaline was attended with great benefit. In all the renal cases the quantity of urea was measured daily by means of the ureameter, and it was found that the injection was attended with an increased quantity of urea in a very short time. Dr. Charteris said he considered the knowledge obtained by this easily-worked instrument invaluable, more so than even the daily estimate of the albumen. The general treatment of the renal cases consisted in hot-air or modified Turkish baths, according to an apparatus constructed by Dr. Whittaker, and at the same time the administration of compound jalap powder on alternate nights. Dialysed iron was found very serviceable, and did not appear to cause headache—a result often apparent when iron is given in its usual form of the perchloride.

No. 2970.

The treatment in the cardiac and hepatic cases was entirely symptomatic. Southey's needles were in these cases inserted. In one they occasioned erysipelas of the leg. This was attributed to the needles being inserted without their previously puncturing boracic lint.

A case of syphilis, the only one admitted during the winter, was treated by a mixture of the perchloride of mercury, iodide of potassium, and chloride of ammonium. The chief advantage of this treatment in well-marked secondary eruptions is the length of time the mercury can be administered beneficially without causing salivation.

Eight cases of acute rheumatic fever came under observation, and six of chronic. The acute cases were all treated with salicin in twenty-grain doses every two hours, with invariably satisfactory results. In all the cases the patient was free from pain in twenty-four hours, and the temperature was normal in forty-eight. When this result had been attained the salicin was given in smaller doses, by twenty-grains every four hours for the first day, and afterwards the same quantity every six hours for two days, when it was stopped and a tonic administered. Dr. Charteris mentioned that he had invariably followed this line of practice for the last four years, and said he could not speak too highly of the remedy. He said he had never known it to cause delirium, or weakening of the heart's action. On the contrary, the relief was marvellous, and the recovery materially hastened. On an average the patient was able to leave the bed within seven days after admission, and no other treatment he had tried could give any result at all to be compared with this. In former years he had tried for comparison the salicylate of soda, but it caused temporary deafness, headache, and insomnia, and he had latterly entirely abandoned it, being more than satisfied with the action of salicin.

Six cases of chronic rheumatism were treated variously. Salicin was found, however, to have no beneficial effect in these.

One case of purpura in its hæmorrhagic form died, but no post-mortem was obtained.

A case of scurvy in a sailor, after a long and arduous voyage, made a good recovery. The hard, board-like induration of the legs and the looseness of the teeth, with the spongy condition of the gums, rendered the diagnosis easy. This man stated that lime-juice was, in the merchant service, carelessly administered, and frequently never taken. He said that there was a common impression among sailors that lime-juice destroyed virility, and he attributed much of Jack's antipathy to it to this idea.

A case of chlorosis and another of anæmia made good recoveries under iron and a nourishing diet.

Only one case of idiopathic erysipelas was admitted, and the perchloride of iron was given in large doses, with the usual satisfactory result.

Diphtheria in a man aged thirty was watched with interest. The fauces were found to be sloughy, the pulse feeble, and the prostration great. The man was placed in a side ward, and inhaled steam constantly from a kettle placed on the hob of a fireplace. Poultices were also applied externally, and iron given with quinine. He made a good recovery, but subsequently was attacked with dropsy, commencing in the abdomen and latterly extending to the extremities. No remedy seemed of any use, and he died three months after admission. At the post-mortem the liver was found to be hobnailed and contracted. The spleen weighed as much as the liver. The kidneys were healthy.

One patient died from laryngitis. Another made a satisfactory recovery. This latter case was interesting, as the symptoms were so grave, the dyspnoea so excessive, and the mal-aeration of the blood so intense, that it was deemed advisable to perform tracheotomy. Acting, however, on the advice of Dr. Eben. Watson, this was postponed, and palliative remedies, notably the inhalation of steam, were put in force. The case progressed favourably, although the dyspnoea was at times very alarming. The patient had an ulcerated sore-throat, and the laryngitis seemed to have originated simply from exposure to cold.

Seven cases of acute bronchitis were treated successfully by antimonial wine for the first twenty-four hours in large doses. This medicine had, as in former years, the effect of promoting expectoration, lowering the fever, and causing profuse diaphoresis. At the same time stimulants were

given as required to meet the attendant weakness, their use being regulated by their action on the circulation. Hot linseed poultices were also applied. At the expiration of the term mentioned, and provided other circumstances warranted it, the antimony was given at an extended interval of time, simply as an expectorant, combined with ipecacuanha wine or carbonate of ammonia.

Twenty-six cases of chronic bronchitis and emphysema were relieved by the usual methods of treatment.

Stramonium cigarettes did good after other means failed in the only case of asthma admitted into the wards.

Of fifteen cases of acute pneumonia, two died in the first twenty-four hours after admission, one on the ninth day, the others made a satisfactory recovery. A similar line of treatment was adopted to that mentioned in acute bronchitis, and Dr. Charteris said he believed that in the main the most favourable result would accrue from its adoption. In four of the cases marked benefit followed the application of twelve leeches to the side affected. There could be no doubt the lividity and other alarming symptoms disappeared *pari passu* with the loss of blood. The bleeding on the removal of the leeches was promoted by hot cloths and poultices.

There were seven cases of pleurisy. In two of these empyema was well marked on admission, and it was singular and instructive to note the methods by which the pus was evacuated. In one case, a man aged twenty-four, there was distinct fluctuation and pointing at the junction of the third rib with the sternum. It was resolved to give the man a day's rest and then aspirate. On the visit the following morning he stated "that during the night he felt something give way in his inside, and this was followed by a choking sensation in his throat, and subsequently by the expectoration of a large quantity of purulent matter." On examination it was found that the skin was much less tense over the site mentioned, and it was deemed advisable not to interfere with nature's processes, but to assist these. Pressure by means of a broad elastic band was used over the side, with the view of preventing the lodging of pus in the sac, and at the same time strict rest and nourishing diet were enjoined. Notwithstanding this, on three different occasions at varying intervals the pus reaccumulated, and was expectorated in a similar manner. The man made a good recovery, and is now following his employment as a nurseryman.

The second case had been aspirated twice by the medical man in attendance, and the patient, a young lad of sixteen, was sent to the hospital as a *dernier ressort*. The patient was very exhausted. The right pleura seemed full of fluid. The liver was pushed down, the intercostal spaces bulged out, and the difference of measurement on the two sides was nearly an inch. As death seemed imminent, a free incision with a bistoury was made in the axillary line, where the skin seemed tensest. There was a copious spouting out of pus at first, succeeded by a more steady flow, to the extent of three pints and a half. The operation was performed under strict antiseptic precautions. A drainage-tube was inserted into the wound and a bandage applied over carbolic-acid gauze dressing. Considerable cough and irritation followed the operation, and the pulse was remarkably feeble. Brandy was given in large quantities, the patient taking nearly a bottle per diem, along with three pints of strong beef-tea. For the first fortnight a carbolic-acid solution was syringed into the wound, and the patient by a series of coughs expelled this through the tube. At the expiration of the fortnight the syringing was only done on alternate days. A satisfactory recovery was completed three months after the operation by the removal of the tube, and the patient is now able to move about freely. Hypophosphite of lime and malt extract were the only medicines given. Large quantities of stimulants were administered during the progress of the case, and without these no recovery could by any possibility have taken place.

Thirty-seven cases of phthisis were admitted in various stages of the disease. Of these five died, and in the others some improvement was manifested, or the disease seemed to remain *in statu quo*. Dr. Charteris said he considered a hospital ward the worst place possible for a phthisical patient in the winter, as the whole surroundings were depressing, and one essential part of the treatment—viz., going out of doors—almost impossible. Dr. Charteris said he had increasing confidence in the hypophosphites as the best remedial measures for phthisis in its early stages.

(To be continued.)

Nettsonian Lectures

ON

THE TREATMENT OF STRICTURE OF THE URETHRA, ENLARGED PROSTATE, AND STONE IN THE BLADDER,

WITH SPECIAL REFERENCE TO RECENT PROGRESS.

Delivered at the Medical Society of London, February, 1880.

By W. F. TEEVAN, B.A., F.R.C.S.,

SURGEON TO THE WEST LONDON AND ST. PETER'S HOSPITALS.

LECTURE III.—PART II.

THE symptoms of stone in the bladder are often very slight and entirely masked by the existence of some chronic irritation with an enlarged prostate, so that on several occasions I have detected calculi in patients who had been treated for cystitis for months and even years. If the act of micturition is associated with pain and blood, and if both be increased by exercise, *there must be a stone*. On the other hand, a calculus may give no evidence of its presence beyond a slight smarting in the urethra. There is no difficulty in finding a large stone, but small calculi are often missed by badly-shaped sounds. The shorter the beak of a sound and the more it approximates to a right angle with the shaft, the more efficient will it be. I consider Mercier's sound (Fig. 11, A), with Sir H. Thompson's cylindrical handle, to be

FIG. 11.

the very best. When the instrument touches a small stone, the two bodies are in contact at points only, for they are both convex, hence the click is very faint, and there is always a tendency for the sound to push away the little calculus. For obviating this and more easily detecting small stones, Mercier devised a hollow sound with a flattened spoon-shaped beak (Fig. 11, B), the concavity of which overlaps the convex surface of the calculus, and as the two opposing bodies have surfaces in contact instead of points only, a louder note is elicited. I prefer to examine a patient when his bladder is quite empty, for there is no trouble in finding a large stone, whether the viscus be full or not; but if the calculus be small and the vesical cavity full, the surgeon may make a prolonged examination and yet fail to strike the particular spot where the stone lies. When, however, the bladder is empty, a small calculus is brought to its

very neck, and is struck by the sound as it enters. Text-books omit to point out that things *extravesical* as well as *intravesical* may be felt with a sound—the sacrum can always be touched, and very often the spine of each ischium. For a want of this knowledge the bladder has been cut into on several occasions, and, to the great mortification of the operator, no calculus found.

When a stone is found, what is to be done with it? In the present state of our knowledge and experience I regard the use of solvents as so much valuable time wasted. Unfortunately, a calculus is too often treated as such, whether it originated in the kidney or bladder, and stones of equal dimensions, whether renal or vesical, are dealt with in a similar manner. I look upon the treatment of a stone which has formed in the bladder to be different from one which originated in the kidney and descended into the bladder, and the want of discrimination on this point has led to many disappointing results after operation. In one case the calculus is the *cause* of all the trouble; in the other it is merely a *result*. Take a man with a lithic-acid stone which is giving him much pain. What are the facts of the case? The calculus descended from the kidney, and until it entered the bladder that organ was healthy and quiet; the bladder, however, finds that it has a very unpleasant guest, and becomes irritated. Get rid of the intruder and the bladder will quickly resume the even tenour of its way. Not so, however, is the case with the phosphatic stone formed in it. Long before the calculus existed the bladder was in a state of chronic inflammation, the urine was mucopurulent, and the patient could probably only empty his bladder with a catheter. In such a case the stone formed as a matter of course, but it was entirely secondary to the vesical condition, and if removed leaves the patient but little better off, for the aches and pains will persist, the urine will not clear up, and a fresh concretion will rapidly form. If the calculus be of renal origin it ought always to be crushed in the adult, if not too large. In the present state of our knowledge and experience, enlarged and improved as it is by the introduction of Bigelow's operation, it may be said that any stone up to two inches in diameter may be crushed, Bigelow's operation has entirely revolutionised the treatment of stone in the bladder: it is a *new* operation. The principles upon which it is founded are as widely opposed to those upon which ordinary lithotomy was established as are the two poles to each other. The old method was sometimes spread over a period of months, the new one is the work of a certain number of minutes; and in this respect resembles lithotomy, the advocates of which operation used to urge that one of its great advantages was that, unlike lithotomy, it rid the patient at once of his trouble. Now this is exactly what Bigelow's operation does. The bladder frets for a few hours at the great liberties taken with it, but not finding any enemy to fight with it rapidly resumes its former wonted quiet. The rule hitherto has been to do as little as possible at the first sitting—feel your way, see how much interference the bladder will tolerate, and, above all, do not let your lithotrite remain in longer than a couple of minutes; leave the fragments to nature to get rid of—unless indeed she cannot do so, in which case you must wash them out, a process "which is quite as irritating as a crushing with the lithotrite." Bigelow says exactly the opposite—do everything at once and for all, however long it may take you to do—leave nothing to nature to expel; remove it all. But it may be said that surgeons performed lithotomy at one sitting and removed fragments before Bigelow's time. Most certainly they did, but they operated on the same principle whether they removed a calculus in one sitting or twenty; and all cases of lithotomy at one sitting were so performed because, as Curtis has pointed out, "a second sitting was an impossibility."

Then, again, the means the older lithotritists adopted to remove fragments or débris were looked upon as more objectionable than the evil they sought to obviate, of leaving the pieces of stone behind. In 1846 Heurteloup wrote a work on "Lithotripsie sans fragments au moyen de deux procédés de l'extraction immédiate, ou de la pulvérisation immédiate des pierres vésicales par les voies naturelles." He named his process "Lithocœnosis" (stone evacuation). Of 124 cases of lithotomy, 69 were performed by him at one sitting.

In 1853 Amussat published a "Mémoire sur la Lithotritie en une seule Séance," and in our own time Sir W. Ferguson was a great advocate for removing fragments with the lithotrite. That these great surgeons did all this detracts nothing from the value of Bigelow's dis-

covery. Cornay of Rochfort was the first to introduce aspiration into practice in 1843, and he originated the truncated catheter. Next came Sir Philip Crampton, then Mercier, then Clover, and lastly Bigelow. It is only just to say that Dr. E. M. Moore, an American, very nearly anticipated Bigelow in his discovery. Up to Bigelow's time aspiration was only partially successful, for two reasons—the small calibre of the evacuating catheter, which only permitted little particles to escape, and the weakness of the india-rubber bottle. Bigelow has made aspiration perfect, but he probably would not have succeeded had it not been for Otis, who demonstrated what large catheters could be introduced into the bladder. *But even if we had possessed Bigelow's perfect instruments, we should not have dared to perform his operation if he had not shown us the great amount of instrumental interference the bladder will tolerate if we only take care to remove all the fragments at once.* This is the grand point, and to Bigelow solely belongs the great merit of the discovery. I consider that his operation will prove an inestimable boon to mankind; it will save life by bringing within the fold of lithotomy a large number of cases which otherwise would have been submitted to the knife with a correspondingly increased risk; it will rob lithotomy of its peril to life in old men who formerly were often worn out by the cystitis set up by the frequent crushings, and it will take from lithotomy the opprobrium that it often removed the stone, but failed to cure the patient. All the aspirators now in use, Clover's excepted, are unconscious copies of Mercier's, whose aspirator (see Fig. 11, C) consisted of an india-rubber bottle, fitted with a brass tube and stopcock to fix on to the evacuating catheter, and a glass receiver for the fragments to fall into. The original one made by Charrière upwards of twenty years ago is now in the possession of Gouley, who has recently recorded a case in which he used it successfully. Bigelow's aspirator, with the stopcock restored to it by me, is seen at Fig. 11, D. Let us see what are the differences between the two. When Bigelow's aspirator arrived in this country it had no stopcock like Mercier's, which was, I think, a great mistake, for air entered the bladder, got churned up with the water, and caused much annoyance. At first I used to put a cork into the india-rubber tube after filling it to the very brim, but in spite of this I found that air would always enter the evacuating catheter during the process of adjusting the two tubes. I accordingly restored Mercier's stopcock, and have experienced no further annoyance. The great improvement in Bigelow's aspirator above all others consists in placing a long piece of india-rubber tubing between the bottle and the evacuating tube. Everywhere we see art imitating nature in placing pads, springs, or buffers between bodies which would otherwise be brought into rude contact, and to fix an aspirator directly on to a rigid tube without an intervening medium to damp the concussion is contrary to all the laws of mechanics, for the shock which takes place each time the bottle is squeezed is transmitted unimpaired to the metal catheter. Then, again, the india-rubber tube acts as a syphon when the aspirator is at work, so that there are two forces in operation. An objection has been made to it that its length diminishes the power of the aspirator; it is, however, purely theoretical, for evacuation, as performed by Bigelow's aspirator, is simply perfect. The glass-receiver, which in Mercier's is fixed, takes off and on in Bigelow's, which is another improvement, and as it is made longer and narrower the fragments cannot escape when once they have dropped in. To English surgeons Bigelow's lithotrite seems somewhat cumbersome, except for breaking up large stones. Until six years ago Civiale's lithotrite was almost universally employed here. Sir H. Thompson improved it by adding to it his cylindrical handle and particular mechanism for fixing the blades. The three special points in Civiale's instrument were—(1) the jaws were placed at a very oblique angle to the shaft; (2) the male blade had no spur; (3) the female blade had only a small pinhole for the ejection of débris. Mercier condemned Civiale's lithotrite, and said it was "l'un de plus mauvais," and his verdict has been fully justified by the accidents which have occurred to lithotrites made on Civiale's principles. These were due to the vicious lines on which they were built. As the jaws were placed so obliquely to the shaft there was much loss of crushing power, for the body of the male blade could not be brought well home to the stone which it crushed with its tip, and as it had no spur it sometimes broke at its weakest part—the angle. Then, again, the female blade had only a

pinhole for the escape of débris, so that the instrument was liable to become "packed" and incarcerated in the bladder. Six years ago, in THE LANCET, I introduced Mercier's lithotrite to the notice of the profession, with a special mechanism of my own for fixing the blades. The three great points on which it is constructed are—(1) the male blade is fixed as nearly as possible at a right angle to its shaft, thus obtaining great crushing power; (2) the male blade is strengthened at its angle by a spur or prow, which also drives out the débris and prevents "packing"; (3) there is a large opening in the female blade for the escape of débris and the reception of the spur. All these principles have been adopted by Sir H. Thompson in the construction of what he calls his "new lithotrite." Figures C and A in woodcut 12 respectively represent Mercier's and Civiale's

FIG. 12.

lithotrites. Compare the oblique angle at which Civiale's male blade (B) is set to its shaft with the almost right angle of Mercier's (D). Compare the spur (E) at the base of Mercier's male blade with its absence in Civiale's. Compare the pinhole in the female blade (A) of Civiale's with the large opening (C) in that of Mercier's. Bigelow prefers his straight evacuating catheter to the curved one. To obviate the difficulty there sometimes is in introducing the former Gouley has fixed a Mercier's beak to it. It appears to me that the curved tube has one advantage which has been overlooked—viz., that the beak keeps the mucous membrane from falling over the hole and obstructing the ingress of the fragments. The old operation of lithotrity will now only be required for small calculi, which can be pulverised in a few minutes, and for which aspiration would be unnecessary. Lithotomy will only be demanded for very large, hard stones; big, soft calculi can be most safely disposed of by lithotrity and external urethrotomy at one sitting.

What are the conditions which bar lithotrity, enlarged as it now is, in its scope by Bigelow's operation? Boys will continue as heretofore to be submitted to lithotomy, for their parts are much too undeveloped to allow of the application of Bigelow's procedure, even if it were desirable; but women are admirably adapted for his operation, for in them the urethra is short, straight, and capacious. In men the only condition to preclude crushing is that contracted condition of the bladder which occasionally exists and interferes with the manipulation of the lithotrite. A strictured urethra can be restored to its normal calibre, and an enlarged prostate can usually be surmounted. No kind or amount of renal disease forbids Bigelow's operation if the patient be physically fit for it. In those cases where the diseased bladder is the cause, and not the result of the stone, I am afraid that his method will no more prove a success than did ordinary lithotrity. In the four instances of lithic-acid calculi in which I performed Bigelow's operation the results were admirable, but in the case of a phosphatic stone of local formation, entirely secondary to a diseased bladder, requiring the use of a catheter, it removed the calculus, but failed to cure the patient. In a recent clinical lecture at the Bellevue Hospital, Gouley has pointed out that surgeons will be mistaken if they suppose anaesthesia and aspiration have rendered lithotrity easier to perform, and that it will, on the contrary, now more than ever demand the utmost care and delicate skill. Very recently Keyes of New York has collected the results of 107 cases of Bigelow's operation performed by English and American surgeons with but six deaths. Nothing could be more satisfactory, and the success achieved far surpasses the results obtained by any other method.

Lithotomy will now only be required in adults for very large hard calculi. For stones up to three ounces in weight lateral lithotomy is an admirable operation, and although much larger calculi have been removed by it, the rectum was usually cut or torn. I consider that the introduction of Bigelow's operation will bring to the front those other forms

of lithotomy which have rarely been practised of recent years. I have a personal experience of everyone of them save the supra-pubic. The bilateral is specially adapted for those stones which are rather too large for the lateral method, for it gives as much room as two laterals. The recto-vesical is well devised for enormous calculi or debilitated subjects, for it can be performed with the minimum amount of cutting and loss of blood, and it affords the greatest amount of space. The extraction of a calculus by it closely resembles the removal of a child with the forceps, for in each instance the presenting body passes through the centre, where there is the most room. Two objections are urged against this operation. It is said the peritoneum may be wounded and that a urethro-rectal fistula may remain. The former may be avoided by making lateral incisions through the prostate instead of a vertical one, and a fistula is not necessarily incurable. According to Dulles' statistics the results of the suprapubic operation for stones above two ounces in weight were far more favourable than those of lateral lithotomy. The operation is specially indicated for large calculi in men who, on account of their enlarged prostates, are obliged to use the catheter, for a small aperture might be kept permanently open for the instrument. Median lithotomy will only be required for large hard calculi which have been "fragmented." In extracting a calculus in lithotomy the surgeon has the choice of removing it by cutting or laceration, for there is no such thing as dilatation of the prostate, as was long ago proved by Professor Ellis. Many years ago I carried out a series of investigations on this point and submitted the results to the Pathological Society, which proved that the normal calibre of the prostatic urethra was much larger than had been supposed, but that it could no more be exceeded than the calibre of any other portion of the canal. I further ascertained from my experiments and from an examination of all specimens of parts after lithotomy in the London museums, that a stone not more than 60 mm. in circumference could be extracted through a non-incised prostatic urethra without laceration. The extreme normal calibre of the prostatic urethra may be regarded as from 50 mm. to 60 mm., and in old men it is often greater. This is an important anatomical fact, for it enables us to take advantage of it and utilise it for breaking up large soft stones and extracting the fragments by external urethrotomy, and so avoiding the severer operation of lithotomy. The examinations made on twelve fatal cases of lithotomy occurring in the practice of one of the most distinguished British surgeons deceased, who professed to extract calculi by a limited incision and dilatation, showed that in every instance the prostate had been ruptured. To prove that the division of the prostate and its capsule is not followed by a fatal result, I need only refer to the twenty-two boys whom I have cut by the lateral method, everyone of whom recovered, notwithstanding the fact that the breadth of my knife exceeded the diameter of the lateral half of the prostate in each instance. The most successful lithotomists were probably Brett, Martineau, and Gutteridge, and the peculiarity in their method was that they used no force when extracting calculi, preferring to enlarge the incision if necessary rather than tear out the stone through an insufficient opening. The fewer the instruments used in lithotomy the better. For boys I employ, as a rule, only a staff and a knife, extracting the calculus with my finger. If, on account of the enlargement of the prostate, the depth of the perineum, or the shortness of his finger, the surgeon is unable to reach the bladder, he uses a gorget. Now, if the probe point on the gorget be transferred to one of the blades of the forceps, as seen at Fig. 11, E, the surgeon can slide the instrument along the groove of the staff into the bladder with unerring certainty. This slight modification of mine renders the gorget unnecessary, and so one less instrument is required. I have given up using the sharp-pointed knife for making the internal incision in men since Mr. Gutteridge convinced me of the risk attending its employment, for if it should slip from the staff, the posterior wall of the bladder will most likely be pierced, and the patient killed by peritonitis. Had the deaths which have occurred after operations through the above accident been published, the sharp-pointed knife would long ago have received its *congé*. In boys it is a choice of evils, for if the surgeon change his knife, he may not be able to introduce the probe-pointed one, and if he fail, he may push the yielding tissues before him, and rupture the urethra. I consequently still use a sharp-pointed knife for them, with a short broad blade, and, by holding it short, lessen the chance of doing mischief if it

should slip. I prefer Mr. Jonathan Hutchinson's rectangular catheter staff to any other. It has two great advantages. The surgeon can determine if the instrument is in the bladder or not, whether he strike the stone or not, for a short-beaked sound may touch a stone when a staff cannot. Then, again, it gives a straight road into the bladder instead of a crooked one, and so the chances of the knife slipping are reduced to *nil*. No tube or plug of any kind ought, I think, if possible, to be retained in the bladder after the operation, for however large a tube may be, it will not allow clots to escape, and if they cannot, they give rise to straining and cause bleeding or prevent its arrest. By leaving the wound open the surgeon sees what hæmorrhage may take place, for cases have occurred of fatal bleeding into the bladder when the wound was plugged. Then, again, the retention of clots which are rapidly decomposed by the urine in a few hours is a likely source of blood-poisoning. If hæmorrhage should occur, the best way to arrest it is to apply an ice-bag above the pubes, and insert pieces of ice in the wound and rectum.

In the treatment of stone in the bladder when it occurs as a local formation secondary to the diseased bladder, of which it was not the *cause*, but the *result*, the following pathological facts must be borne in mind:—Firstly, the condition of the bladder is such that, even if the calculus be completely removed by crushing and aspiration, some local irritation will remain, the alkalinity of the urine will persist, and a speedy recurrence of stone take place; secondly, the condition of the prostate in these cases not only does not improve, but gradually becomes more troublesome as age advances, and auto-catheterism is rendered increasingly difficult. The following indications have to be carried out:—1. Remove the stone. 2. Cure the cystitis. 3. Give the patient a short and ready route to his bladder for the catheter. A case such as the above is in this country too often relegated to lateral lithotomy, which is unnecessary and uncalled-for, for directly the surgeon has grasped the stone with his forceps it crumbles to pieces, and the operation, instead of being a speedy one, becomes a prolonged one, for he has to extract some twenty or thirty pieces, during all which time the man's engorged prostatic plexus of veins pours out blood like water. In devising an operation for such a case, we must take cognisance of the following facts. The stone is soft, and can on the slightest pressure be reduced to fragments small enough to pass along the normal urethra. An incision into the bladder is therefore unnecessary; but we want to cure the cystitis which caused the calculus, and this can only be done by allowing the urine to run out as fast as it enters the bladder, and so give it a physiological rest. We require further a short route for the catheter to go into the bladder. External urethrotomy fulfils all these conditions. All we have to do is to reduce the stone to fragments with the lithotrite, extract them through the perineal puncture, and wash out the bladder, leaving in a tube for drainage: the small puncture being kept permanently open for catheterism. It will at once be seen that whereas lateral lithotomy was a dangerous operation, and the wound could not be utilised for future catheterism, this combination of mine is attended by but little risk, comparatively speaking, and the aperture can be made useful for catheterism. What is it that makes lithotomy a perilous operation whilst external urethrotomy is not? It is because the former is an *intra-pelvic* operation, whilst the latter is an *extra-pelvic* one. Thus, therefore, by reducing the lateral lithotomy to a mere external urethrotomy, we shall diminish the rate of mortality correspondingly. I believe I was the first to introduce this combination, and in the unpromising cases in which I performed it, it was followed by the best results. But it may be asked, Is not this the perineal lithotomy of Dolbeau? It is not. There are two objections to this operation. In the process of dilating the urethra with instruments the urine always escapes, and the canal is very likely to be injured. The stone has consequently to be broken up in an empty bladder, which is a difficult and dangerous procedure if it be large, and during the long and tedious process the patient is bleeding, and no means can be taken for its arrest. Dolbeau cut first and then crushed the calculus through the perineal wound. I, on the contrary, crush first through the penis, and then cut. The operation of breaking up a large stone during lithotomy into several small ones is of ancient date, and is called "fragmentation" by the Americans, to distinguish it from lithotripsy, which it is not. I consider therefore that

the combination of a perfect lithotripsy at one sitting, followed immediately by external urethrotomy, is the proper treatment for large phosphatic calculi in men who are the subjects of chronic cystitis, and who are obliged to use the catheter; for we remove the stone at a minimum risk, we give the bladder the physiological rest it requires, and we convert penile catheterism, which in these cases is often a painful, bloody, and difficult process, into perineal instrumentation, which is free from all these annoyances. Last August I published the results of my first series of one hundred consecutive cases of operation for stone in the bladder; it is not, therefore, now necessary for me to trouble you with statistics.

In bringing these lectures to a close, I would express my regret that time has only permitted me to glance very cursorily at some of the more salient points of my subject; and I desire to thank you very sincerely, Mr. President and gentlemen, for the kind and cordial reception you have given me.

ON THE ANTI-MALARIAL ACTION OF THE CHINCHONA COMPOUNDS.

By T. J. MACLAGAN, M.D.

THAT quinine cures ague is one of the best established facts in practical therapeutics. How it does so we do not know. And it is impossible that we can know until we have some idea of the nature and mode of action of the ague poison. The existence of this poison is known to us only by its effects. These effects are the various forms of malarial fever.

Malarial fevers are most prevalent in marshy localities, in which there is much decomposing vegetable matter. Whatever puts a stop to this decomposition seems to arrest the development of the miasmatic poison. Cold weather, the complete drying up of the marsh, its drainage, even its submergence under water during a wet season, seems to have the effect of checking the spread of malarial fevers. These are exactly the circumstances which would check vegetable decomposition.

Marshes situate near the sea, and liable to inundation by it, are, *ceteris paribus*, more malarious than those which have no admixture of salt water. Salt water kills freshwater plants. Marshes liable to such inundation thus contain more decaying vegetable matter than those whose water is always fresh.

Malarial fevers are most common in autumn, when the vegetable matter formed during the summer begins to decay, and while the heat necessary to its rapid decomposition still prevails.

The association of malarial fever with vegetable decay is undoubted. What is the nature of the association?

Finding it all but invariable, the conclusion was not unnaturally drawn that the malarial poison was a product of vegetable decomposition; and various gaseous products of such decomposition have been suggested as possibly constituting the toxic agency. It has been found, however, that not one of these produces malarial disease.

Many marshes, too, contain much decomposing vegetable matter, and present all the conditions indicated as requisite to the development of malaria, without being a source of malarial disease. Where malaria prevails vegetable decomposition is generally abundant and active. But the converse does not hold good; for vegetable decomposition may be abundant and active in a locality which is not malarious.

No product of vegetable decomposition has been proved to be competent to cause intermittent and remittent fevers, and no causal connexion has been established between vegetable decay and the occurrence of these maladies. But there is another view of the matter, another possible explanation of this association.

Malarial fevers are most common in autumn, when vegetable decay is most active. But decay is a mere sequence of death, and death simply the cessation of vital activity. Autumn marks the time at which the annually-recurring active growth of plants comes to an end. The increased prevalence of malarial disease in autumn is thus associated with the cessation of the growth of living as much as with the decay of dead vegetable matter. It is possible that the association may be with the former rather than with the

latter, and that the arrest of the processes which constitute vegetable activity may have more to do with the development of malarial diseases than has the occurrence of the changes incident to vegetable decay.

Malaria exists in the ground, emanates from it, and infects the atmosphere in its neighbourhood. Of this there is ample evidence:—

1. The diseases to which it gives rise are associated with certain conditions of the soil.

2. Such disturbance of the ground as cultivation implies often leads to the development of these diseases.

3. The poison does not operate at more than a certain height above the sea-level.

4. Those who sleep near the ground are more apt to suffer than those who are more elevated.

A poison which is in the ground, and which infects only that part of the atmosphere which is near the ground, has its seat in what may be called the vegetable tract. The chief area of malarial infection is the area of vegetable influence—the ground in which the roots are, and the atmosphere immediately around the leaves.

Now, supposing the malarial poison to be (as it almost certainly is) something which may be taken up and absorbed by plants during their growth, it is evident that less of the poison would be spread abroad and be available for the production of disease during spring and summer, when vegetation is active, than in autumn, when the cessation of growth would leave much of it free; while the cold of winter might check the development of malaria as well as of vegetation. Thus the autumnal development of malarial fever may be causally associated with the autumnal cessation of vegetable growth.

Evidence in support of this view is found in the purifying effect of vegetation on a malarial atmosphere, as testified to by some facts noted in a study of the natural history of malarial fevers.

The marsh poison is carried about in air currents, and may thus give rise to malarial disease at some distance from its home. These malaria-laden breezes may be robbed of much of their deleterious properties, and rendered comparatively innocuous, by having to pass through a belt of trees. On the other hand, the cutting down of trees has been followed by the development of malarial fever in localities which have thus been opened up and exposed to direct currents from a malarious district.

It is claimed for some trees and plants, and not without some show of reason, that they possess the property of removing malaria, and rendering a district more healthy. The one quality common to the trees and plants which have been so commended is rapidity of growth, implying great activity of the nutritive process. We know that malaria may be taken into the system of man either through the lungs, or in drinking-water through the digestive organs. There is no reason why it may not in like manner be absorbed by plants, either from the atmosphere by the leaves, or with water by the roots, or by both channels. There is no other mode in which vegetation as such could produce a purifying effect on a malarial atmosphere.

The cessation of vegetable growth in autumn would thus explain the autumnal prevalence of malarial fever. The poison which produces that fever may be as abundant in summer, but the active state of vegetation at that season leads to the absorption of much of it by the leaves and roots of plants, and to the consequent removal of much of the poison from the soil and atmosphere. In other words, malaria seems to be developed during the hot season, but it is chiefly at the latter part of that season, when ordinary vegetation ceases to be active, that it has full scope for its disease-producing powers.

Again, malarial atmospheres are more deadly during the night than during the day. The literature of the subject abounds with instances in which the members of a ship's crew who went ashore in a malarial district only during the day escaped, while those who remained all night suffered from malarial fever. This deleterious effect of night air is well known to dwellers in malarial districts, who during the day go freely and with impunity into places which they would not think of visiting at night. No satisfactory explanation has ever been given of this. It has been supposed to be due to chilling of the body by night air, but the night may be oppressively hot, and the result is the same. It has been attributed to the lowering of vitality during sleep; but sleep may be indulged in during the day with impunity, and being awake at night does not protect from danger. Dr.

Mitchell of Philadelphia thought that malarial poisons^s were allied in nature to the fungi, and that, like mushrooms, they grew during the night. It has been supposed, too, that vapours which are dissipated abroad during the day, and are again condensed near the ground at night, may contain the malarial poison, and that it may be dissipated, and again condensed, with the vapour.

But none of these views would explain the purifying effect of vegetation on a malarial atmosphere. Another factor is almost certainly at work. If the view which has been advanced as to the mode in which trees act as purifying agents be correct, it necessarily follows that this action must be less during the night than during the day, for night is the time at which leaves cease to perform their absorbent function, and at which, therefore, they would cease to exercise a purifying influence on a malarial atmosphere.

The view that the malarial poison is absorbed by plants and trees is the one which best fits into and explains the facts with which we have to deal.

But still the question remains, "What is the nature of this poison?"

The opinion most generally entertained nowadays is that the malarial poison consists of minute organisms. "I have no hesitation," says Niemeyer, "in saying decidedly that marsh miasm—malaria must consist of low vegetable organisms." Though the evidence is scarcely sufficient to warrant so strong a statement, there can be no doubt that this is the view which best accords with the phenomena noted in connexion with the origin and spread of malarial disease. The usual objection to this view is that, if such were the nature of the poison, its existence could be demonstrated by the microscope. But that by no means follows. The microscope can demonstrate the existence of very minute organisms; but beyond a certain point it cannot go. And it has to be borne in mind that the limit to microscopic demonstration of such minute objects is not the mechanical power of the microscope, but the visual power of our eyes. An object may be magnified 30,000 times and be visible, and yet disappear from the field of our vision when magnified 60,000 times. The object is there, but its image is so attenuated by the increased power of the microscope that our eyes can no longer detect it. Professor Tyndall has demonstrated that the atmosphere habitually teems with particles so minute that they cannot be detected by the highest powers of the microscope, and that many of these particles are organised. With the knowledge that organised particles so minute do exist, we cannot fail to see that our inability to demonstrate that malaria is particulate and organised is no proof that such may not be its nature.

Certain it is that this view is the one which best explains the phenomena with which we have to deal. Adopting it, we can at once see (1) why a damp locality favours the development of malarial fever; for moisture is favourable to the development of organised life; (2) why the drying up of the soil and the onset of cold weather lead to an opposite result; for such conditions check the growth of organisms; (3) why complete flooding of a marsh has the same effect; for such an event puts a stop to direct communication between the soil and the atmosphere. (4) This view gives also an adequate explanation of the purifying effect of growing plants and trees on a malarial atmosphere. If malaria consists of organisms so excessively minute that their size can be no obstacle to their absorption by the roots and leaves of plants.

The recent researches of Lanzi and Terrigi,¹ and the still more recent ones of Professor Klebs and Signor Tommasi-Crudeli,² made in the malarial district of the Agro-Romano, near Rome, point to the conclusion that the malarial poison is an organism which may be obtained from the soil, and may be cultivated in the bodies of animals. This organism, say the last two observers, belongs to the genus *Bacillus*, and exists in the soil of malarial districts in the form of shining ovoid spores: to it they propose to give the name of *Bacillus malarie*. By inoculating rabbits with liquids taken directly from malarial soil, and containing this bacillus, there was produced fever, often of an intermittent type. Another result of such inoculation was enlargement of the spleen.

It is apparent that authority and evidence favour the view that malarial poisons are minute organisms. Such being the case, we shall assume that they are so, and shall proceed to investigate the probable mode of action of such organisms

¹ Centralblatt f. Med. Wiss., 1875.

² Allg. Wien. Med. Zeit., No. 28, 1879; and London Med. Record, Oct. 15, 1879.

on the system. For if this view of their nature be correct, the phenomena to which they give rise in the system must be such as an organism would produce; and a detailed consideration of these phenomena will tend to throw light on the true nature of the poison which causes them.

Malarial poisons may act like ordinary medicinal and poisonous agencies; they may act after the manner of contagia, and have their action intimately connected with their organic development; or their mode of action may be altogether peculiar. To say that malarial poisons act like ordinary medicinal and poisonous agencies is not to explain their mode of action, for of the manner in which many of these produce their effects we know little or nothing. Malaria differs, too, so widely from such agencies, both in its nature and in the effects to which it gives rise, that it is likely also to differ from them in its mode of action.

That contagia are organisms, and that their morbid action is intimately associated with and dependent on their organic growth are propositions which I have elsewhere³ considered and maintained in some detail. The evidence in support of this view may be briefly summed up as follows:—

1. The effects produced in the system by a given contagium bear no relation to the quantity administered—a small dose acting, if it act at all, as vigorously as a large one.

2. During its action the poison is largely reproduced in the system.

3. The quantity eliminated from the system is always greatly in excess of that received into it.

4. The locality in which its action is most marked—the seat of the local lesion in the eruptive fevers, for instance—is also that in which the poison exists in largest quantity.

5. The action of the poison ceases while the system still contains a much larger quantity of it than sufficed to cause the disease to which it gives rise.

6. The maladies produced by the contagia are communicable from the sick to the healthy.

The existence of such peculiarities creates a broad line of demarcation between contagia and ordinary medicinal agencies. They also separate them from malaria: for in malarial disease there is not the same evidence of organic reproduction; there is no evidence of elimination of the poison; and malarial fevers are not communicable from the sick to the healthy.

The question of the mode of action of malaria is, indeed, beset with peculiar difficulty; for, unless possibly in the experiments of Klebs and Tommasi-Crudeli, already referred to, the poison has never been separated and experimented with.

If malarial poisons are organisms—and the evidence all favours the view that that they are so—they are more likely in their mode of action to resemble contagia than ordinary medicinal agencies. It is to be noted as evidence in support of such a view that the phenomena to which they give rise in the system are more analogous to those resulting from the action of contagia than to any effects ever produced by ordinary poisons and medicines.

Both contagia and malaria are intangible agencies introduced into the system from without. Both are associated with bad hygienic conditions. Both have for the most striking of their effects on the system the occurrence of idiopathic fever. In each of them the fever is specific in nature, and in each it has a more or less distinctive course.

The existence of such analogies constitutes a reasonable foundation for the view, not only that malarial poisons are allied in nature to the contagia, but that they are also likely to resemble them in their mode of action. If they act after the manner of contagia, and owe their effects to their organic development within the system, we shall find evidence in support of this view in a detailed consideration of the phenomena to which they give rise.

The essential characteristics of the form of fever which is universally regarded as of malarial origin are its intermitting or irregular course and its occurrence independently of a local inflammatory cause. The question which we have to consider is the competence of an organism to produce such a result.

That the reproduction of an organism in the system is capable of producing the essential phenomena of the febrile state, I have in the case of the continued fevers shown in some detail.⁴

An organism has for its most distinctive characteristics: (1) the power of organic reproduction and development, and (2) a certain action on its environment. This latter is dependent on the former, and consists mainly in the consumption of nitrogen and water. But nitrogen and water are the very materials required by the tissues of the body. The propagation in the system of millions of organisms having such wants, must lead to an enormous increase in the consumption of these materials. This means simply the development of fever, for such an increase must give rise to quickening of the circulation, increased tissue-waste, increased consumption of water, rise of temperature, and increased elimination of urea. This aggregate of phenomena constitutes the febrile state. The propagation in the system of such organisms as I believe malarial poisons to be is, therefore, competent to the production of the most prominent and essential feature of the maladies to which these poisons give rise—idiopathic fever.

(To be concluded.)

ON THE TREATMENT OF CHRONIC INFLAMMATORY AFFECTIONS OF THE JOINTS IN CHILDHOOD, WITH ESPECIAL REFERENCE TO EXCISION.

(PART OF A CLINICAL LECTURE.)

By HOWARD MARSH, F.R.C.S.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN AND TO THE HOSPITAL FOR HIP DISEASE; ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

AFTER discussing the nature of chronic inflammatory affections of the bones and joints in childhood, and arriving at the conclusion that, although they often follow an injury, they are generally something more than traumatic, and depend on the presence of the tubercular diathesis—which however is often so far modified in transmission, by admixture with other constitutions, or with a healthy stock, as to lose what are usually regarded as its characteristic features,—and after referring to Sir James Paget's views on the minor signs of constitutional diseases,¹ the speaker continued:—The belief that they are modifications of tuberculosis may seem to stamp these diseases as highly intractable, or even, as many regard them, little better than incurable. Happily, however, experience leads to quite an opposite conclusion, and proves that a large majority of these cases may be cured without any remaining impairment of the functions of the limb.² This is a matter of great practical importance, for chronic affections of the joints constitute a very large part of the more grave surgical diseases of childhood. Every year hundreds of children are crippled by them, and the misery they entail is deplorable.

The method of treatment by which these cases may be cured has long been before the profession. It consists in keeping the affected parts at complete rest, and in good position, by means of leather splints or some similar appliance, so that deformity is prevented; and in the use of remedies against the tubercular diathesis. It would be needless to insist on the value of what may seem to you so well known and commonplace a scheme of treatment, were it not that there are many who appear not to believe in its efficiency; for almost every week cases are brought to the hospital which have been treated merely with tonics and blisters or with mercurial ointment, or tincture of iodine, while the affected joint has been steadily growing worse, and more and more distorted. In many of these cases, especially of knee disease, nothing remains to be done but excision or amputation, or to advise the patient to make the best he can of a distorted and crippled limb, for we possess no means by which, when the tibia is once displaced in relation to the

¹ Clinical Lectures and Essays, second edition.

² Observation shows that the intensity or virulence of tubercle differs in different structures and in different individuals; while it flourishes in some tissues, there are some in which it is rare, and others in which it is never found. Even in the lungs it is not always inveterate, but is often found retrogressive, or already obsolete; and it may be that bone and synovial membrane are structures in which it is prone to be immature, or, under favourable circumstances, even to abort.

³ The Germ Theory applied to the Explanation of the Phenomena of Disease. By T. J. MacLagan, M.D. (Macmillan and Co., 1876.)

⁴ MacLagan, op. cit.

condyles of the femur, this distortion can be corrected. In the following remarks the hip is excluded. The diseases of this joint require special appliances, the details of which I have already ventured to describe.³

Although there are several methods by which rest may be more or less satisfactorily secured for diseased joints, the most convenient, as I have already mentioned, consists in the use of well-made leather splints. They must be long enough in the axis of the limb to give thoroughly efficient support. This is especially important for the knee and the elbow. For these joints the splints should extend as high as the upper fourth of the thigh or upper arm, and as low as nearly to the ankle or wrist. The elbow should be put up just within a right angle; the knee as nearly straight as it can easily be brought; the wrist slightly flexed, and the ankle very carefully at a right angle with the leg. Should the ankle be fixed with the heel at all raised towards equinus, the calf muscles are prone, by shortening themselves, to lead to troublesome contraction of the tendo Achillis. The parents are directed to take off the splints once a day, to readjust them, and see that the skin is sound; but with this exception they are worn constantly day and night. They are cut away over any sinus there may be, and wherever threatening suppuration produces local tenderness. If when first seen a knee is found to be contracted, it is put up without any attempt to alter its position. The surrounding muscles under the influence of rest soon relax, and then the joint will gradually become extended, so that the original splints no longer fit. These must now be exchanged for a straighter pair; and these again, in their turn, must give place to a pair adapted to the limb when it has reached the straight position. This spontaneous extension of a limb may be regarded as a sure sign that the state of the joint is steadily improving. These remarks refer only to simple flexion. If there is dislocation, splints can do little, as I have said above, to remove it.

The leather of which the splints are made must be carefully selected. Their credit is often damaged by the use of the wrong material. Common sole leather contains a good deal of grease, and has been compressed in the process of manufacture. This kind remains stiff and clumsy, even after prolonged soaking. You must use leather from which all grease has been removed and which has not been compressed. Such leather, when soaked for five or ten minutes in water at a temperature of about 120°, to which a little vinegar has been added, becomes perfectly flexible and limp, and will either stretch or close like wet flannel, so as to adapt itself to the uneven surfaces of a limb as accurately as a plaster-of-Paris mould. To make the splints take patterns of the two aspects of the limb in brown paper; cut out two pieces of leather according to these, but a little larger in all directions, and, when they are soaked, apply them closely and smoothly to the joint, letting them overlap at their borders; then fix them with a flannel bandage, and leave them for twelve hours to dry and harden upon the limb. Now trim them so that they just meet around the limb without overlapping; cut them away over the front of the patella and bevel their edges, and, with the help of thick paste, line them with chamois-leather; and furnish them with wide webbing straps fastening with buckles.

I know there are many to whom the idea of keeping joints so long at rest does not commend itself. But, in the first place, the repair of diseases so tenacious as these affections are cannot but be otherwise than slow; and, after all, we encounter here only the same difficulties as we meet with in cases of enlarged glands, of ophthalmia, otorrhoea, or ozæna. All these affections demand a large amount of patience. And is it not incumbent on those who reject this method to say what alternative can be adopted? How do they cure these cases? One objection accepted by many as weighty against the principle of long-continued rest is that the joint may become ankylosed. I am convinced this fear is groundless. Experience shows that ankylosis does not occur. A child with well-marked synovitis of both knees of ten months' duration wore splints for upwards of two years, yet her joints, which are now quite sound, preserve their full normal range of movement. Many similar cases might be reported. I have never seen ankylosis occur except in cases in which there has been either acute or long-continued suppuration. Indeed, even if suppuration has lasted for many months ankylosis, whether bony or fibrous, is by no means always the result. I have notes of many

cases of repaired hip disease in which, though suppuration existed for periods varying from six to twelve months or even longer, considerable movement remains in the joint. But besides their beneficial effect on the course of the disease itself, the leather splints serve another purpose. They entirely *prevent deformity*. This is a point of the very first importance. As long as you keep these diseased joints in children free from distortion there is—except in all but very rare examples of acute suppuration or where the articular ends of the bones are widely involved—good ground for hope that their cure may be effected. But who has not seen cases in which, though extensive disease of the knee has been completely repaired, the limb is rendered useless by the amount of distortion which has taken place; or others in which, though the disease has never been more than slight in itself, so much deformity has gradually supervened that the joint is irreparably spoilt? But you will ask, Is surgery unequal to the treatment of these distorted joints—are not these just the cases for excision? I grant these, if any, are the cases for which excision is appropriate; cases, that is, in which there is little or no disease, but much distortion. But the point is that you excise a joint not because it is the seat of incurable disease, but because it has been allowed to get out of shape. Prevent the deformity and the necessity for excision vanishes.

As I have mentioned excision, let me review the position which this operation seems at present to hold in the treatment of diseases of the joints.

There was a time when these diseases were "touched" or treated by some charm or quack nostrum. Next came the amputation period, in which diseases thought to be incurable were got rid of by the simple expedient of cutting off the limb. Numbers of limbs in those days were cut off not only for advanced disease of a large joint, but for abscess in the articular ends of the bones, and even for neuralgia and hysteria. The age of amputation was followed by the age of excision. Some thirty years ago Sir William Fergusson attacked the too prevalent fashion of amputation, and, holding that however admirable a wooden leg might be a limb of flesh and blood was better, proposed to save the limb by cutting out the affected joint, and thus was founded a school that became the most popular of its day under the seductive title of conservative surgery. But conservative as excision undoubtedly was as compared with amputation, it embodied no final result; it was only a link in the chain of progress; and where Fergusson left the work it has been the duty of those who have followed him to take it up. Nor have they failed to do so, for whereas excision was performed some twenty years ago for a variety of conditions, it is now, by nearly common consent, resorted to in only a comparatively few carefully selected cases. This change of opinion respecting excision, especially in childhood, has no doubt been due in part to an increased experience of its dangers and its drawbacks in regard to the future condition of the limb. But it has also been largely owing to the same conservative spirit which led Fergusson to the happy expedient of excision as a substitute for amputation. Many surgeons have found that by treating these joint diseases in their early stages, so severe a measure as excision can, in the great majority of cases, be avoided, and that, even in their later stages, they may be successfully dealt with by aspiration, drainage, or free incision, under the safeguard of due precautions.

I know that I am not expressing a unanimous opinion. Some operators still frequently resort to excision, even for incipient disease, and point in triumph to the admirable results they obtain. The proceeding has, it is said, hitherto so often failed because it has been performed too late. Only perform the operation early enough, and the cure is safe and rapid. We learn from the cases that are published that excision, done under the agis of the antiseptic method, is shorn of all its dangers: there is no surgical fever, the wound heals quickly, and the patient is up and walking about not in so many months, but in so many weeks—nay, almost in so many days. These are, no doubt, important facts, yet they do not suffice to prove that excision is the proper treatment for these cases. The rapid healing of a wound is one thing: the future of a limb out of which the knee-joint has been cut is another. It must be remembered what excision is. It is not the cure of disease, but the cutting out of the diseased part. It is not reformation, but capital punishment. It is like the practice of a dental surgeon, who, instead of stopping a tooth, beginning to be carious, should at once extract it; or like that of an ophthalmic surgeon, who, instead of trying

³ Brit. Med. Jour., 1877.

to cure an eye, should forthwith proceed to remove it. No doubt amputation itself is still the readiest method of relieving patients of many forms of disease. The wound heals rapidly enough; but the objection to this short cut to a cure is that the patient finds himself minus a leg. In the same way, after an excision, the patient's wound may heal without a check (though it does not always do so); but, then, he has lost his knee-joint, and this is surely not a light matter. The limb after excision of the knee in childhood, so far as present experience goes, is always stiff, short, and atrophied, and, not rarely, it is deformed; and until different results can be shown—not, of course, in a few exceptional instances, but as constituting the rule—I must rank myself with those who believe that real progress lies, not in the encouragement of an earlier and more general resort to excision, but in the demonstration of the fact that if these cases are kept at rest and in good position their cure is, in the great majority of instances, simply a question of time; and that if they are so treated while they are incipient they may be cured without any, or with very slight, impairment either of the structure or the function of the limb, and much more speedily than perhaps many have supposed.

May not a substantial argument against the frequent use of excision be drawn from the fact that the operation is next to never performed in private practice? If it is so excellent a method, why is it not recommended by the leaders of surgery to their rich patients? Why are not the rich to avail themselves of it as they do of ovariectomy, of lithotomy, of operations for strangulated hernia or the removal of tumours? But it will be said that the circumstances of the well-to-do are so different from those of the poor, that what is possible in the one class is impossible in the other. This is an argument which may fairly be used in respect to the past, and, though with diminished force (for circumstances have much changed for the better), to the present. But what has been, and to some extent still is unavoidable, through the want of hospital accommodation and a system of home nursing, that such important parts of the body as the large joints should be cut out when in a state of scarcely more than incipient disease, on the plea of saving time—that disease, that is to say, should be treated not upon its merits, but according to the external circumstances of the patient; that there should, in other words, be one rule for the rich and another for the poor; that while the rich child is cured by three, six, or nine months' rest, the poor child, to whom a sound limb is one of the necessities of life, shall submit to all the risks of what must always remain one of the most formidable operations in the surgery of childhood, and be subjected to, I had almost said, a mutilation, but at all events a loss, which leaves him a cripple, however sturdy and however resigned—this is a state of things which will certainly not be allowed to continue. We constantly see that what is the exclusive and costly privilege of the rich in one generation, becomes, in the next, the unchallenged possession of the poor, and I cannot doubt that, with the reconstruction of our hospital system, which is so much required, and which we are promised in the near future, means will be provided for the efficient treatment of these joint affections in childhood—treatment which, being applied while cases are incipient, and being carefully carried out, will render excision as rare among the poor as it now is among the rich.

BEQUESTS ETC. TO MEDICAL CHARITIES.—The Clothworkers' Company have given thirty guineas to the National Hospital for Consumption, &c., at Ventnor, twenty-five guineas to the Seaside Convalescent Home at Seaford, twenty guineas to the North Eastern Hospital for Children, twenty guineas to Queen Charlotte's Lying-in Hospital, and twenty guineas to the Cancer Hospital. Mr. R. K. Hodgson has given £50 to the Charing-cross Hospital. The National Hospital for Consumption, &c., at Ventnor, has received £50 in memory of J. A. S. Freeland. The Mercers' Company have given £25 to the Royal Kent Dispensary, Greenwich, out of the funds of the Earl of Northampton's Charity. The General Hospital, the Queen's Hospital, the Children's Hospital, and the General Dispensary, all at Birmingham, have received £100 each under the will of Mr. J. R. Mott. Mr. Robert Few has given £100 additional to the Charing-cross Hospital. The Grocers' Company have given £100 to St. George's Hospital. Addenbrooke's Hospital, Cambridge, has received £50 under the will of Miss Matilda Abbott.

A NOTE ON AN OUTBREAK OF RUBEOLA (RÖTHELN).

By W. R. GOWERS, M.D., F.R.C.P.

DR. DYCE DUCKWORTH's remark, in a recent paper, that our knowledge of "rubeola," or "German measles," is still so imperfect that all cases of the affection deserve description, induces me to place on record a brief note of a series of cases which I had an opportunity of closely watching about two years ago. A nursemaid, exactly a fortnight after entering a household, presented a rash on her face, chest, and arms. She had been suffering from cold and slight sore-throat (apparently a simple catarrh) for four or five days. There was slight elevation of temperature (about two degrees). The eruption on the chest closely resembled that of scarlatina, the spots being confluent; on the arms it was nearly like measles, but rather brighter in tint. It was, in fact, thought probable that it was measles, and she was sent to the Fever Hospital. When she reached the hospital the rash had almost disappeared (as I was afterwards informed by Dr. Murphy), and she was quickly well. The eruption had lasted about thirty-six hours. It was not noticed until fully out, and she was then attending to two children—one aged two and a half, and the other three months—and she undressed them both and put them to bed whilst the rash was out. An hour or two afterwards it was discovered, she was separated, and did not again see the children or their mother. Exactly fourteen days subsequently the latter (who had had true measles), after a day of malaise, presented a rash which was at once recognised as "German measles." It was "measly" in distribution, but brighter in tint, and commenced on the backs of the forearms. In the evening slightly elevated spots were seen, on which, by gaslight, no abnormal tint was visible; but next morning arms, face, and chest were covered with an unmistakable rash. She was at the time suckling the youngest child, and did so during that night. In the morning the child was separated and weaned. Two days later the mother's rash had entirely disappeared. She remained secluded from the children for two days more, and then returned to them, but did not again suckle the baby. Just a fortnight later both the children presented a rash exactly like that of the mother, but slighter. It lasted about twenty-four hours, and then disappeared. Their indisposition was trifling.

In this case the period of incubation certainly in the mother, and probably in the nursemaid, was just a fortnight. The fact that the children were more exposed to the contagion than the mother, and yet did not contract the disease from the nursemaid, is remarkable, and corroborates the fact observed before that adults are as liable to the disease as children, if not more liable. The period of incubation in the children was either eighteen days (if contracted before their separation) or fourteen days (if contracted after the mother rejoined them). The latter seems much the more probable. So long an incubative period as eighteen days has not, I believe, been observed, and fourteen days was distinctly the period in the mother. If so, it would seem that the contagion was much stronger two days after the disappearance of the rash than it was when the rash was at its height—a very important practical fact.

I would ask those who may have an opportunity of observing the rash in the early stage to note whether it is common for the elevation to precede the blush, and whether it is common for the eruption to commence on the backs of the forearms. Of course, it is only in cases, as in this, in which the most careful look-out is kept for the earliest symptoms that these points can be noted. If corroborated they would possess diagnostic importance.

It seems highly probable that a large number, perhaps all cases, of sporadic rash, in which doubt is felt as to whether the case is one of scarlet fever or of measles, are cases of this disease.

In none of the cases of this series was there any enlargement of the lymphatic glands. It is possible that there may be more than one distinct disease to which we apply the terms rubeola and rötheln.

Queen Anne-street, W.

NOTE ON THE USE OF LARGE PROBES IN THE TREATMENT OF LACHRYMAL OBSTRUCTION.¹

By SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE SCHOOL FOR THE BLIND.

THE plan of treatment in the class of cases indicated by my title, at present most generally adopted and introduced by Mr. Bowman, has undoubtedly rendered immense services. Successful, however, as it is in many instances, experience shows, I think, that there are a good number which appear little benefited by it, and after the probes have been passed several times in succession there is still a recurrence of the obstruction.

For some time I have been under the impression that the probes commonly used were not large enough for the purpose for which they were intended—viz., to restore the narrowed duct to its normal calibre. The analogy of the introduction of large urethral sounds by Otis, interested me somewhat in this direction, and I was, moreover, chiefly influenced by the utter disproportion that the probes showed to the size of the duct as represented in the anatomical subject.

Authorities, strange to say, while all describe accurately the length of the nasal duct, with few exceptions are silent as to its width. The calibre would, however, appear to vary somewhat. According to one authority it would measure from just three millimetres to four millimetres; and to another from three millimetres to four and a half. I have, moreover, satisfied myself in the dry skull that often the passage of a four-millimetre probe is very easy, whilst in other ducts, even in the same skull, it is difficult.

The disproportion between these measurements and those of the probes will be at once apparent, when it is stated that the largest of the set of probes in general use is a millimetre or little more. The bulbous probes used by Mr. Teale are larger, and the biggest of the set I possess is about two millimetres, and I should add that I fancy I remember seeing Mr. Bowman employ a larger probe at Moorfields some years ago.

The large probes which I now use I was induced to have made after reading an article in Knapp's "Archives of Ophthalmology" (vol. vi.), by Dr. Theobald of Baltimore on the use of large probes in strictures of the nasal duct. The probes are made after his scale. There are sixteen; the smallest is $\frac{1}{2}$ mm., the second $\frac{3}{4}$ mm., third $\frac{1}{2}$ mm., and so on; the twelfth being 3 mm., thirteenth $3\frac{1}{2}$ mm., fourteenth $3\frac{3}{4}$ mm., fifteenth $3\frac{1}{2}$ mm., sixteenth 4 mm. The smallest are intended merely for exploring the canaliculi. The probes are conically ended to facilitate introduction. In any case of stricture it has been my custom to use, in the first place, one of the smaller probes—a millimetre or a millimetre and a half, or less—according to the tightness of the stricture, following it immediately by a larger one. At the visit the next day, or following one, another probe still further increased in size is introduced, and so on.

During the past year (1879) I have used these probes in about twenty cases, and as yet have not seen the necessity for the four-millimetre one, but have found those ranging from about 3 mm. to $3\frac{1}{2}$ mm. the most useful. Dr. Theobald, however, stated that he had frequently employed the largest size even in young persons.

Judging from the cases in which thus far I have adopted this method, I certainly incline to the opinion that it is superior to that with the smaller probes, that the results have been better and more rapid, and that it is worthy of extended use.

Since the above was written, six months ago, I have continued the employment of this method, and have treated several additional cases by it. I have no reason to think less favourably of it, but perhaps more so. Weiss is at present engaged in making another set of the probes for me. The number of the small probes will be reduced, the larger ones will be of a different size at either end, and bent to avoid the prominence of the forehead. A reduction in the number will be thus effected, without interfering with the utility of the gradual gradations in size.

Sheffield.

¹ Read before the Leeds and West Riding Medico-Chirurgical Society, Feb., 1880.

CASE OF EXTRA-UTERINE FCETATION, SIMULATING OBSTRUCTION OF THE BOWELS.

By JOHN WHEELER, M.D., CH.M., L.M.

MRS. S—, aged forty-four years, of sallow complexion, has borne one child twenty-three years ago, since which time she has not been pregnant. Was married to her second husband ten years since. Was seized with violent abdominal pains and vomiting on Saturday evening, March 6th, immediately after partaking of some oysters. She sought medical aid in the night, but was unable to procure it. I saw her for the first time about 1 o'clock on Sunday afternoon, the 7th inst., when her condition was as follows:—She was lying on her back with knees drawn up; countenance anxious; extremities cold; teeth chattering; pulse 140; quite conscious; tenderness all over abdomen; no action of bowels or bladder; obstinate and almost incessant vomiting, or rather regurgitation of thin grumous matter; extreme thirst. She attributed her painful condition, &c., to the oysters she had partaken of the day before. I found upon inquiry that, though the menses had ceased about the end of December last, and having noticed an enlargement of her breasts, she consulted a medical man as to her condition, who introduced the sound, and informed her that she was not pregnant.

Looking upon the case as an aggravated one of gastric disturbance with constipation, I, after injecting a sixth of a grain of morphia subcutaneously, with the object of alleviating the pain and vomiting, ordered turpentine stupes to abdomen, and prescribed five grains of subchloride of mercury to be taken immediately, and to be repeated in six hours if the bowels were not relieved, and to have iced soda-water, with milk and beef-tea. At 6 P.M. there was no improvement in her condition. Ordered an enema, composed of turpentine and castor oil. 9 P.M.: Same condition. Passed catheter, and drew off about one pint of urine. Repeated enema, which had no effect. Pulse now small, weak, and irregular, 150.

March 8th. — 10 A.M.: Spent a restless night; had no sleep; pain over abdomen increased; still vomiting; no action of bowels or bladder. Ordered effervescing soda draught with tincture of orange, to be repeated every two hours. — 2 P.M.: No change in symptoms. Ordered to suck ice. — 6 P.M.: Same condition as at 2 P.M. To have twenty grains of subnitrate of bismuth every two hours. Met Dr. Ryan, of Ladbroke-grove, in consultation between 11 and 12 P.M. Vomiting still persistent. Administered enema of sulphate of magnesia; and upon proceeding to draw off urine, found a sanguineous discharge flowing from vagina having the menstrual character. We now decided to give her two grains of calomel with a quarter of a grain of opium, to be repeated every two hours.

9th. — 10 A.M.: No improvement; no action of bowels; no urine passed. — 2 P.M.: To have an enema with long tube of sulphate of magnesia, which returned slightly coloured. — 4 P.M.: Injection repeated, which had the effect of bringing away a small quantity of liquid faecal matter. — 8 P.M.: Sickness the same; abdominal pain and tympanitis increased. She objected to the enema being repeated.

10th. — 11 A.M.: Had no rest during the night; no sleep; everything administered by the mouth returned at once; abdomen more tympanitic and exquisitely painful. Ordered an enema containing two drachms of tincture of opium, part of which only was retained. — 6 P.M.: Injected subcutaneously one-third of a grain of morphia, which alleviated pain and vomiting temporarily. — 10.30 P.M.: On my asking her if she wished the morphia injection to be repeated, she was sufficiently conscious to make me understand that she did. I accordingly injected a quarter of a grain subcutaneously.

11th. — Died at 3 A.M.

Autopsy, twelve hours after death (Dr. Ryan and Mr. E. T. Ensor being present). Body well nourished and still warm. The abdomen was laid open by a vertical incision through the integument from the ensiform cartilage to the pubes, and a second incision commencing midway between the umbilicus and pubes transversely outwards to the anterior superior spinous process of the ilium; the muscles were also divided in the same direction. The flaps were then re-

flected outwards, thus exposing the contents of the abdominal cavity.

My attention was immediately arrested by two large black clots lying in the folds of the ileum, which were removed. The stomach was next removed and examined; it contained about a pint of fluid, which was found to be chiefly beef-tea and milk. It was quite healthy, and presented no appearance of inflammation. The small intestines were next carefully removed. They were also healthy. Large intestine also healthy. Special attention was paid to vermiform appendix, which was healthy. The large and small intestines were empty; bladder contained about half a pint of urine; kidneys, liver, and spleen were healthy; also peritoneum; no adhesions. In the left inguinal region a tumour somewhat ovoid in form, larger than the uterus (which was natural in size), of a dark red colour, was found imbedded in clots. This proved to be an abnormal development of the left ovary. The clots with surrounding blood were removed, when a male embryo (about eight weeks), three inches long, came into view. I thereupon removed tumour, uterus, and appendages *en masse*. Upon examination of the tumour a rent was perceptible behind and at right side, from which evidently the hæmorrhage took place. The fimbriated extremity of the Fallopian tube was attached to the ovary, all trace of the fimbriae being lost. The right ovary and Fallopian tube were normal, the former presenting several Graafian vesicles in every stage of development, and one well-marked corpus luteum.

Remarks.—1st. As to treatment. I wish to lay stress upon the value of the subcutaneous injection of morphia, which was the only remedy that seemed to give relief. 2nd. As to duration of life. It was remarkable that the patient should live so long—nearly four days and a half—seeing the amount of effusion and her inability to retain food of any kind on the stomach.

Pembridge-gardens, W.

TRAUMATIC TETANUS TREATED BY CHLOROFORM INHALATION; RECOVERY.

By FREDERICK A. GRAY, L.R.C.P. LOND., &c.

RECOVERY from traumatic tetanus is sufficiently rare to make it worth while recording any case in which treatment seems to have assisted in bringing about such an issue. In the case of which notes are here given chloroform inhalation was attended with the happiest results, relieving completely the spasms, which were severe and increasing in severity, and threatening suffocation every few minutes.

James Y—, aged ten years, was admitted to Cottage Hospital March 29th, 1879. Fourteen days before admission he caught his left hand in a turnip-cutter, which crushed the middle finger. It had been attended to by a surgeon at the time, but does not seem to have been dressed again till the 25th, he having left the neighbourhood. On the 25th he went to another surgeon, where he had his hand dressed; he then complained of some stiffness and pain of the jaws, and afterwards of pain and stiffness in his back and severe pain in the pit of his stomach, which was of an intermittent character. These pains got worse and more frequent up to the time of his admission.

On admission, March 29th, the middle finger of the left hand was in a very unhealthy condition, the soft parts sloughy, and the bones comminuted up to the second joint, the end of the finger hanging by tendons, and gangrenous. The jaws were almost fixed, and the teeth could not be separated more than a quarter of an inch. Fluids could be swallowed with great difficulty, any attempt producing severe spasm. Opisthotonos well marked, returning every two or three minutes, when pain in the epigastrium was most severe, and the muscles of the abdomen became hard as a board with each recurrence of the spasm. The facial muscles were affected also, and the "risus sardonius" was well marked. The spasms were most severe, causing the patient to be jerked up in the bed, bent back, with teeth clenched and breathing suspended, till he seemed in imminent danger of suffocation, his complexion assuming an almost black hue at times.

Having been placed under chloroform, the mutilated finger was amputated at the metacarpal joint. During the time he was under chloroform there were no spasms, but

they soon began to return on the effects passing off. Hydrate of chloral and bromide of potassium ordered, ten grains of each; this at first relieved the spasm, but soon lost its effect, though the dose was increased.

March 30th.—Determined to keep him under the influence of chloroform, and chloroform inhalation was substituted. This had the effect of preventing spasms altogether if thoroughly under its influence, and he would remain almost free for a couple of hours after, when the inhalation would have to be commenced again. Strong beef-tea and milk were given at regular intervals, when he was allowed to come from under the influence of the anæsthetic. The bowels, which were very costive, were kept open by castor-oil enemata. These proceedings were continued up to the 6th of April, during which time the spasms maintained the same intensity and frequency when the influence of the chloroform was removed. After this the spasms began to abate, and in a few days gave place to twitchings. The chloroform was gradually lessened and then discontinued. The twitchings continued for some days, and were perhaps kept up by some ascarides, of which a dose of santonin relieved him. The wound had in the meantime healed almost by first intention, and the boy was discharged, apparently none the worse for his dangerous illness, on the 15th of April. The total quantity of chloroform inhaled was 3 lb.

Ottery St. Mary.

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

(Cases under the care of Mr. FRANCIS MASON.)

MR. MASON has at the present time, or recently had, under care several cases of more than usual interest.

Large Fungating Cystic Adenoma of Breast; Removal; Recovery.—In the women's ward there is a patient, aged twenty-nine, who for the past twelve years has suffered from disease of the right breast. The tumour, which was removed on Saturday, the 17th inst., was about the size of an adult head. It commenced in a small nodule, and steadily increased in size. About one month before admission the skin on the outer side gave way, so that a fungating mass protruded. The tumour had never been painful, and caused no inconvenience whatever, excepting from its size and from the skin wound. There was no glandular enlargement in the axilla, and the patient was in every other respect perfectly healthy. The removal of the tumour was readily effected by a single straight incision, and no skin was taken away excepting a ring around the fungating mass. Mr. Mason remarked on the importance of not taking away the skin in such cases, for it was only stretched over, and was not in any way implicated by the morbid growth, and in this instance, as is usual, immediately after the operation, it so contracted that there was no redundancy. The antiseptic spray was not used, and dry lint was applied as a dressing. On the second day after the operation, the temperature having reached 101°, a fresh dressing of wet lint was employed. On the following day the temperature was about normal, and the case is now making satisfactory progress.

An examination of the tumour showed it to be a cystic adenoma, which, had it been left, might have undergone a spontaneous cure by sloughing of the skin and enucleation of the growth. It was really simple in character, but just the kind of tumour that fifty years ago would have been styled malignant, soft cancer, or fungus hæmatodes.

Hip Disease, Excision.—In the adjacent bed is a little girl, eleven years old, who was admitted about six weeks ago in a most deplorable state of emaciation from disease of the hip-joint. It was determined to operate without delay, as the little patient was evidently being worn out with the discharge, and there were frequent and painful startings at

night. No better proof could be adduced of the advantage of surgical measures in such cases. There were three or four sinuses leading up to the joint, but they were so placed that they could not be utilised at this operation. The usual incision was therefore made over the great trochanter, and the head, which was much absorbed, and the femur were removed at the line of the trochanters. The acetabulum was examined, and found to be free from disease. Beyond having a few hypodermic injections little else was required in the shape of treatment. The child is now convalescent, and looks remarkably fat and well, the wounds being quite superficial.

Genu Valgum.—In the next bed is a case of genu valgum. About a month ago Mr. Mason divided the lower end of the left femur of a girl, aged ten years, transversely, using the antiseptic spray during the operation. The dressings were kept on for three weeks without the least rise in the patient's temperature. Then they were removed, and the wound was quite healed; but as there was a want of firmness in the part the splint was reapplied, the antiseptic dressings being discontinued. The osteotomy was performed from within outwards. In another patient, a girl aged six years, a similar operation was performed, and the antiseptic dressings were not touched for a fortnight. At the end of six weeks the child was discharged with a straight and very useful limb.

Cases of Fracture.—Whilst there are several cases of compound fracture which are progressing most favourably under the antiseptic dressings, there are two cases of simple fracture of more than ordinary interest—one occurring in a woman, aged fifty-eight, who broke her right femur at the junction of the upper and middle third. On examining the bone it was found enormously thickened, and at first gave the idea that there was some growth investing the bony structure and thus weakening it. But, as showing the value of comparing the limbs, the left femur was found to have exactly the same appearance. The woman has a sallow aspect, and says that although she has generally enjoyed fair health, yet she has never been what may be termed strong. The case is being treated with a long outside splint with extension. The other patient is a man, about forty-five years old, who has a simple fracture of the right femur, just below the trochanter, and he states that he has broken the bone in the same place twice before—five years ago and two years ago respectively. In this case there seems nothing about the patient to account for the fragility of the bone.

Suppuration of the Antrum.—In Leopold ward there is a lad, aged seventeen, with suppuration of the antrum. He was quite well until January last, when he noticed a swelling under his right eye, which burst, giving exit to an ounce or two of pus. On his admission there was a fistulous opening, very small indeed, in the situation referred to, and there was also an aperture on the outer side of the first upper molar tooth, the stump of which was left. Under ether Mr. Mason removed the stump, and its removal was immediately followed by the discharge of about two ounces of offensive pus. The bone in the neighbourhood was freely gouged, so as to enable the point of the little finger to be introduced into the antral cavity. A piece of lint was passed into the antrum, and within a fortnight a complete cure has been effected. The small sinus under the right eye has quite healed; but as there is a depressed cicatrix, it will be desirable at some time to divide the adhesion subcutaneously. Had there been any difficulty in removing the stump it was intended to open the antrum with an ordinary joiner's gimlet, as we believe was suggested by Mr. Samuel Smith, of Leeds. (See THE LANCET, Feb. 14th, 1857, p. 160.) A peculiar circumstance in this case was the entire absence of fetor in the discharge. In many of these instances the antrum is filled with a more or less solid material resembling putty, and giving off an intolerable stench.

Plastic Operation.—Two interesting cases are under treatment. The first is a patient, aged twenty-six, who, about eighteen months ago, lost the greater part of her nose from sloughing after the application of strong nitric acid for a small ulcer. Three months ago Mr. Mason formed a columna from the upper lip and fixed it to a surface made raw over the nasal bones. Unfortunately, the patient was attacked with erysipelas, and a portion of the flap sloughed, but the lower part remained as a good basis of support. About three weeks ago two bridges of skin were raised from the cheek on each side of the nose, and lint placed under them. In ten days the under surface was granulating freely, and the lower end of each bridge was divided, and the two

flaps approximated in the median line and fastened together with silk stitches. At the present time the nose is very presentable, and with another small operation a very good result is anticipated. This method of procedure seems preferable to taking a flap of skin from the forehead, which necessarily leaves a somewhat ugly scar.

The other case is of a poor boy, aged four, with extroversion of the bladder. This, too, is as yet incomplete, but the first step has been successfully accomplished by raising a bridge of skin from the scrotum and bringing it over the penis. The prepuce was brought down and fastened to the lower raw edge of the remainder of the scrotum. In this way about the lower third of the exposed mucous membrane of the bladder is covered. The next procedure will be to take other flaps or bridges of skin from the abdomen after Professor Thiersch's method. We hope to supply a more complete account of these interesting cases at some future time.

ROYAL INFIRMARY, LIVERPOOL.

CASE OF DIABETES PRESENTING PECULIAR FEATURES.

(Under the care of Dr. GLYNN.)

FOR the following notes we are indebted to Mr. Bredin:—Peter E—, collier, aged fifty-four, was admitted to ward 12 on Feb. 24th. Eleven months before he found that he was passing water rather oftener and in larger quantity than previously. He rapidly lost weight, suffered from extreme thirst, and voracious appetite. For six months previous to admission he felt too weak to do any work and passed as much as sixteen quarts of urine in twenty-four hours.

On admission he was much emaciated (weight had fallen from 11 st. 3 lb. to 8 st. 7 lb.), the skin was dry, and the left angle of the mouth was excoriated. The tongue was very dry and rough. Pulse 75; arteries rather hard and tortuous; pulse tracing showed rounded summit; percussion note impaired over right base; breath sounds slightly enfeebled; vocal resonance diminished. Both crystalline lenses were hazy. Urine 94 oz., light yellow, acid; sp. gr. 1032.

Ordered a diet consisting of 4 oz. of bread, well toasted, three times a day, two pints of milk, chop, tea; to take one drachm of dilute phosphoric acid in a pint of water as a drink. Feb. 26th. — Urine 104 oz.; sp. gr. 1040; urea 195.87 gr.; glucose 3590.9 gr. Temperature, morning 97.8°, evening 98°. — 28th: Urine 110 oz.; sp. gr. 1041. Temperature, morning 97.8°, evening 97.4°.

March 3rd. — Patient felt much stronger, thirst was much less, and he had gained 4 lb. in weight. Urine 50 oz. Temperature, morning 97.8°, evening 98°. — 5th: Urine 48 oz.; sp. gr. 1034. Temperature, morning 99°, evening 99°. — 8th: Urine 52 oz.; sp. gr. 1037. Temperature, morning 97.8°, evening 98°. — 9th: Urine 48 oz.; sp. gr. 1033; urea 525 gr.; glucose 1371.37 gr. — 10th: Temperature, morning 99°, evening 98°. Urine 52 oz. — 11th: Temperature, morning 99°, evening 97.4°. Urine 54 oz. — 12th: Temperature, morning 99°, evening 98°. Urine 56 oz. — 16th: Temperature, morning 99.6°, evening 98°. Urine 50 oz.

On the morning of the 17th the temperature was 99.4°. The respiratory movements were equal on both sides; vocal fremitus was greater over right than left apex and base. The percussion resonance was impaired over right lung in front from second to fourth ribs; apex hyper-resonant. Breath-sounds were feebler over the right apex. There was crepitation between second and fourth ribs on right side; audible in right interscapular region, not over apex. Respiratory murmur was louder over right than left base. Vocal fremitus was greater over right apex and base. No cough. Evening temperature 98°.

18th: Temperature, morning 97.8°, evening 98.5°. Urine 46 oz. — 19th: Temperature 98°; pulse 72. Urine 60 oz.; acid; sp. gr. 1034; no albumen; urea 91.98 gr. (.35 grm. in 100 cc.); glucose 1979.9 gr. No headache; pupils normal. — 20th: Temperature 98.8°. Urine 50 oz.; acid; sp. gr. 1033; no albumen; urea 109.5 gr.; glucose 1690.9. Patient refused to remain in hospital.

The urea was estimated by Russell and West's method, the hypobromide-of-soda solution being always freshly prepared immediately before use. On March 19th and 20th, when only 91.98 gr. and 109.5 gr. of urea were passed during twenty-four hours, the analysis was performed twice, with identical results. Glucose was estimated by means of Fehling's solution.

Remarks by Dr. GLYNN.—In this case the ordinary ratio between the glucose and urea excreted was not only maintained, but the amount of urea was absolutely and very greatly diminished. This did not arise apparently from any intercurrent renal disease, as there was not a trace of albumen in the water, and though there was some increased arterial tension there was no cardiac hypertrophy, no displacement of heart's apex, &c. Neither was there any error, I believe, in the analyses, as they were most carefully performed by my clinical clerk Mr. Bredin.

The pulmonary complications were, as they often are I think in diabetes, latent, with the physical signs of marked disease of the right lung. There was neither cough nor any elevation of temperature.

LUXOR HOUSE OF HEALTH.

LARGE TUMOUR IN THE RIGHT TEMPORAL REGION ;
REMOVAL ; RECOVERY ; REMARKS.

(Under the care of Mr. MACLEAN, M.B.)

THE following case, besides its surgical interest, like others which have been recorded in our columns, gives a glimpse of some of the peculiarities of the Egyptian Fellaheen. The name of this institution has curious associations. The natives of Egypt object to enter "hospitals" on account of the bad reputation that the rude surgery of the ignorant native doctors has given them. Instead of being called a hospital, the institution of Luxor is called a House of Health (*Beyt Lissahah*). This useful hospital, consisting of five beds, was started by Mr. Maclean, and is supported by the voluntary contributions of travellers on the Nile.

Hassan M—, aged thirty, agricultural labourer, Mahomedan faith, from the village of Carnak, near Luxor, applied for assistance in the winter of 1877-78; but for some reason never returned, nor did he present himself during the winter 1878-79. In the month of February, 1880, he again applied for relief, and on being asked why he had not come before, replied that he had dreamt that the "doctor" had removed his tumour successfully.

The patient was a very healthy specimen of a Fellah with no other ailment than a large tumour opposite the right temporal region. This tumour was freely movable, hard,

and the skin over it was loose; three lobes could be made out, the two lower being much the smallest and of a hardness approaching that of cartilage. The scalp was greatly hypertrophied and thickened, and lay in folds. The tumour lay over the temporal muscle and had been growing for ten years. The patient was admitted on February 13th, 1880.

On Saturday, February 14th, with the assistance of the secretary of the hotel and a young German gentleman

staying there, the tumour was removed by an oval circular incision. The superficial temporal artery and anastomosing branches of the occipital, posterior auricular, and supra-orbital were divided, together with a number of large veins. Thirteen hemp ligatures were applied, and the edges of the wound brought together with silk stitches, except in the middle, where there was a deficiency of skin. The patient lost a good deal of blood, vomited his breakfast, and felt a little faint at times during the operation, when he took a little brandy, the total quantity amounting to about an ounce. The wound was dressed with pads of dry lint and cotton-wool, kept in position with a firmly applied roller. After the dressing the patient felt no pain, and when put to bed complained of hunger. The tumour weighed four pounds, and measured eight inches by six inches. It was composed of three lobes, each lobe being contained in a distinct capsule. On section the upper and largest lobe was seen to be yellow, and composed of fibrous and fatty tissue, with patches of caseous degeneration, and small cysts containing serum scattered here and there. The middle lobe was only about one-fourth the size of the upper lobe, much darker in colour, approaching that of muscle. The lowest lobe was of about the same size as the middle one, and of a paler tint. At 5 P.M., about six hours after the operation, patient's pulse was 92, and he was free from pain. He slept well; there was no bleeding, and no pain. Pulse 104.

On the 16th the dressing was removed, and a slight swelling, due to the presence of blood and serum, was found. The bandage was replaced. He had great pain during the night.

On the 17th, at 4 P.M., the wound was dressed, and all the stitches were removed on account of the great tension. There was a good deal of oozing. Pads of lint soaked in carbolic oil (1 to 10), cotton-wool and firm bandage were applied.

On the 19th, at 4 A.M., Mr. Maclean was called by the infirmarian man because patient had lost a great deal of blood, and had fainted. The patient was insensible, almost pulseless, and the bed and floor were covered with blood. The wound was opened up, and a large quantity of firm clot turned out. It was then found that the bleeding was for the most part parenchymatous. In the process of turning out the clots several ligatures were torn away, and in one case, on account of the soft pulpy state of the tissues, an armed needle had to be passed in deeply, so as to surround the bleeding point. The wound was then dried piece by piece with lint, the drying of each piece being immediately followed by the application of a strong solution of perchloride of iron. There were now fifteen ligatures. The wound was dressed with lint dipped in carbolic oil, and a light bandage was applied. During the day the pulse ranged over 120, and the patient was constantly sick after the smallest quantity of food till the afternoon. On questioning the infirmarian man, it came out that Hassan was very proud of his strength, and from the very day of the operation had been in the habit of getting out of bed and sitting up, and in this way, no doubt, had succeeded in preventing the proper closure of the bloodvessels.

On the 20th the pulse was 134. The patient was very pale, complained of bad smell from the wound; fresh carbolic oil was applied. Patient had been thoroughly frightened, and now kept very quiet. Next day he was better, and pus ran freely from the wound.

On the 27th the wound was granulating healthily. Pulse 88.

On March 1st patient was looking well. Sweated at night, but felt strong. Pulse 96.

On the 15th patient was in very good health, and was discharged, as the hospital had to be closed in consequence of the termination of the season. The wound was a healthy, superficial, granulating sore of oval shape, measuring in length eleven centimetres, in width at the middle seven centimetres, and four centimetres in width at the junction of the middle with the upper and lower thirds. There was still some deformity about the right eye due to the loose and relaxed condition of the connective tissue under the orbicular muscle, and the position of the pinna was a little faulty. This, however, will probably be corrected by the cicatricial changes, and so far from the deficiency of skin covering at the time when the tumour was removed being a loss, it is a positive advantage, helping to restore the symmetry of the patient's face.

Remarks.—The points of interest about the above case are: 1. The large size of the tumour. 2. The performance

of the operation without anæsthetic. Apropos of this, it is worth mentioning the fact that, as a rule, the Egyptian Arab is endowed with great passive courage. This has perhaps partly resulted from the lavish use through many generations of the kurbág or hippopotamus-hide whip in collecting the taxes. The reward of him who bears his lashes manfully being his escape from the payment of money. Moreover, the women value a man according to his power of bearing blows. Another remarkable circumstance in Egypt is the comparative absence of squalling and crying children. In playing amongst themselves children often submit to things that would certainly cause an English child of the same age to utter an expression of pain. These facts show that the sense of pain in the Egyptian Arab is much less than it is amongst Europeans. An exception has to be made in the case of hasheesh or opium smokers, both of whom bear pain very badly. 3. The occurrence of intermediary hæmorrhage. That this hæmorrhage, though so severe, came from no single bleeding point and was completely controlled by the application of perchloride of iron. 4. The occurrence of vomiting during the operation although no anæsthetic was used. This was due to a syncopal condition, and suggests that some of the cases of vomiting put down to chloroform may be due to the shock inflicted by loss of blood. 5. The vomiting recurred on taking food into the stomach after the patient suffered from intermediary hæmorrhage. Can some of this vomiting have been due to the absorption of perchloride of iron by the wound, or was it all due to the syncopal condition?

Reviews and Notices of Books.

De la Méthode Sanglante dans les Rétrécissements de l'Urèthre. Par le Dr. W. GRÉGORY, Ancien Interne de l'Hôpital Saint-André, Professeur de la Faculté de Médecine de Bordeaux. Paris: Adrien Delahaye et Cie. 1879.

Précis Clinique des Affections des Voies Urinaires chez l'Homme. Par le Dr. CHRISTIAN SMITH, Bruxelles. Tome premier: Anatomie, Urologie, Affections de l'Urèthre. Paris: A. Delahaye et Cie. 1880.

The Pathology and Treatment of Venereal Diseases. By FREEMAN J. BUMSTEAD, M.D., LL.D. New York. Fourth Edition, revised, enlarged, and in great part rewritten by the Author, and by ROBERT W. TAYLOR, A.M., M.D., Professor of Skin Diseases in the University of Vermont. With 130 Woodcuts. Philadelphia: Henry C. Lea. 1879.

THE three works at the head of this notice differ very much in their plan and scope, and yet in the ground they cover so overlap that it is convenient to group them together for the purposes of reviewing.

Dr. Grégory's essay commences with a long and full account of the history of urethrotomy, in which he traces its origin, the way it then fell into disfavour, and its ultimate re-establishment as a sound operation. A number of cases occurring in the Saint André Hospital at Bordeaux are then detailed, and cases and statistics published by British, Continental, and American authors are added, and from these the author draws a comparison between internal and external urethrotomy. The entire purport of the essay is to show that the perineal operation should replace the intra-urethral one in all strictures requiring incision which are not in the penile portion. Dr. Grégory has been at great pains to obtain all the statistics calculated to facilitate the comparison between the two operations in their results, and although we cannot but be struck with his evident bias in favour of the external operation, the facts he gives enable his readers to form their own conclusions, and they are a formidable indictment against internal urethrotomy. In 915 cases of internal urethrotomy there were 46 deaths, or about 5 per cent., and of 992 cases of external urethrotomy there were 88 deaths, or nearly 9 per cent., but Grégory maintains that the operation is only responsible for a mortality of 3 per cent., while the internal section, when similar deductions are

made, has a fatality of 4½ per cent. But further than this, we are assured that Listerism will deprive the perineal section of all its terrors, and render it quite innocuous, by guarding the patient from his chief danger—blood-poisoning. When the question of mortality is put aside it is an easy task to show that the complications of the internal operation are both formidable and frequent; we drew attention to this subject some few years back as illustrated by the University College Hospital statistics. The French cases afford numerous instances of urinary fever, profuse hæmorrhage, urinary infiltration and abscess. As to the ultimate benefit conferred, it is maintained that while recontraction is the exception after external, it is and must be the rule after internal urethrotomy, even when the section of the stricture is complete. We doubt if either operation need be praised by condemning the other. Is it not more just to state that each is useful in its own peculiar field, and that it is by combining them in our practice that we shall best be able to appreciate their value? We hold, for example, that Syme's operation can never replace the intra-urethral section in strictures in the penile urethra, and we must refuse to assent to the proposition that would teach us that because internal urethrotomy is well suited to strictures in that portion, it must be the best method of attacking those in and near the bulb. Unfortunately internal urethrotomy at present is practised too exclusively by specialists, who are often prone to follow out some special line of practice, and are less able than general surgeons to estimate rival (?) treatments at their proper worth. We must wait longer before in this country we can discuss Dr. Grégory's proposition without prejudice, but his brochure will do good service in drawing attention to the merits of the external and the risks of the internal operation.

Dr. Smith's *précis* is a careful readable *résumé* of our knowledge of the diseases of the urethra. As an Englishman he has, of course, made himself well acquainted with the work of British authors, and throughout his pages constant reference is made to their writings. Like other modern authors—and amongst them Bumstead and Taylor—he is at pains to combat the time-honoured notion of the specific nature of gonorrhœa. The evidence adducible on this point is convincing. The history of the establishment of this apparently simple fact is very instructive, for it shows how long it takes to counteract the mischief done when a great man makes a mistake. Hunter wrote of gonorrhœa as a variety of syphilis, and it was long before it was clearly and conclusively separated from it, and it is only lately that this error has been quite dispelled, and the disease declared to be a simple local affection.

Bumstead's work is already classic and hardly requires reviewing. This edition is well up to date, and everywhere bears marks of careful and erudite preparation. Not only is gonorrhœa claimed to be a "simple" affection, but evidence is adduced to show that "chancreoid is distinct from syphilis," that "it does not depend upon a specific virus of its own, incapable of being generated *de novo*," and that, although commonly produced by inoculation of discharge "from another chancreoid, it may arise, especially in persons debilitated from any cause, from inoculation of the products of inflammation either simple or syphilitic, and subsequently perpetuate itself from one individual to another as a chancreoid." The confusion of chancreoid with syphilis has been so widespread and disastrous that we are glad to draw attention to Bumstead's very clear statements and evidence on this point. In this connexion, too, we may note that the specific nature of gonorrhœal rheumatism is rejected by our authors. They refuse credence to Otis's statements about the frequency of spasmodic stricture of the urethra, for they do not believe in spasm lasting through years. The chapters on syphilis are very good, and are the

most valuable part of the work, which altogether must take first rank among the works in the English language on venereal diseases.

Bristol Royal Infirmary Reports. Vol. I. 1878-79. Bristol: J. W. Arrowsmith.

WHILST it is a pleasant duty to welcome every new effort at extension of medical and surgical research, it is none the less incumbent upon the critic to temper his congratulations with a word of warning. It may not always be an easy matter to collate essays of the style and character contained in this first volume, and with every good wish for the successful issue of the enterprise, it is impossible not to feel a little misgiving at the prospect of its maintaining the high standard of excellence assumed. The volume, it may be gathered from these forebodings, is an ambitious one. It is based on the plan so familiar to us in Guy's, St. Bartholomew's, St. George's, and those Reports that used to issue from the London hospitals, the very excellence of which made one feel their extinction all the more deeply. We have numerous essays, many of great interest, from the pens of members of the infirmary staff, a few records of interesting cases, and a much condensed statistical summary of the cases under treatment during the years 1878 and 1879. There are two separate papers on diseases of the spinal cord. Dr. Long Fox contributes an able summary of the present state of knowledge on the subject of Acute Myelitis; and Dr. Shingleton Smith, in an excellent essay, discusses Spinal Sclerosis, which he illustrates with the careful and elaborate notes of cases observed by him in the infirmary. Then follows an original and painstaking paper on Chronic Osteo-Arthritis, by Mr. Greig Smith, full of careful histological details, abundantly illustrated by drawings. The subject is one about which so much obscurity rests, that this contribution to its minute pathology will be welcomed. The same writer also contributes a paper on the Mode of Growth of Spicular Osteophytes, and in these two essays he shows himself to be a careful student in the difficult path of osteal pathology. A pleasantly-written paper, by Dr. Beddoe, on the Progress of Public Health, and a somewhat discursive but most ingenious essay on Fever as a connecting link between Scrofula and Tuberculosis, is contributed by Dr. W. H. Spencer. A melancholy interest attaches to the two papers which follow; they are the records of the rare diseases which deprived Bristol of two of its most able workers—Mr. Crosby Leonard and Dr. R. W. Tibbits,—the former, contributed by Drs. Fox and Shingleton Smith, being a case of Myelitis, the latter, by Dr. Brittan, one of Thrombosis of both Middle Cerebral Arteries. The medical superintendent, Mr. Lee Macintire, gives a report upon Ethidene Dichloride as an anæsthetic, from which it would appear that the administration of this compound, although productive of less cardiac depression than chloroform, was attended by more vomiting and other distressing sequelæ that somewhat detract from its advantages. Several surgical and medical cases of interest are given in full, and obituary notices of Crosby Leonard and William Budd close the literary matter of a volume, upon the excellence of which the Bristol Infirmary is to be congratulated.

Martin's Atlas of Obstetrics and Gynecology. Translated by FANCOURT BARNES, M.D. London: H. King Lewis.

MARTIN'S Atlas consists of a series of lithographic plates with letterpress, which is not descriptive but explanatory. The plates are in great part selections from the works of various authors in England and on the Continent, while a certain number are original to the author. The value of such a work will depend upon two things—the judgment used in the selection and the clearness and accuracy of the drawings. On the whole we think the author has exercised a sound

judgment in the selections he has made; but he has fallen into one error at least—namely, the introduction of diagrams. Diagrams may be and often are of the greatest value in illustrating and making clear views and opinions, but they may be true or not true, and in a work of this kind nothing should be introduced but what had been copied from nature. The editor has perpetuated this error, and has moreover fallen into a second—namely, the introduction of copies of photographs. Photography has been employed for the production of illustrations in several departments of medicine, but in so far as we know without much success. Winckel's photographs of pathological conditions of the female pelvic organs form no exception, and the plates of these photographs introduced into the second edition of this work want clearness and definition, and convey no accurate idea of the subjects represented. The translator has added four plates of wood engravings. Some of these are diagrams, and consequently of little value; others, again, are from nature: all are poor specimens of the art of wood engraving. Why the drawings of instruments at the end should have been added we fail to understand. The translator has done his work fairly well on the whole. His chief fault has been a too close adherence to the original.

The Quarterly Journal of Microscopical Science. April and July, 1880. Nos. LXXVIII. and LXXIX. Edited by E. RAY LANKESTER. London: J. & A. Churchill.

THE seventy-eighth number of this journal contains the following memoirs:—1. The Coffee-leaf Disease of Ceylon, by Thiselton Dyer. 2. On Shephardella—a new Rhizopod, by J. Siddall. 3. The Development of the Kidney in relation to the Wolffian body in the Chick, by Adam Sedgwick. 4. The Development of the Araneina, by F. M. Balfour. 5. The Biology of Bacteria, by Waldstein. 6. Some Teachings of Development, by E. Schäfer. 7. The Histology of Hydra fusca, by T. Parker. 8. The Orthonectidæ, by Alfred Giard.

The seventy-ninth number contains—1. A Chapter on the Structure and Homologies of the Germinal Layers of the Embryo, by F. M. Balfour. 2. Hubrecht's Researches on the Nervous System of Nemertines. 3. The Structure of the Nephridia of the Leech, by G. Bourne. 4. On Intra-epithelial Capillaries in the Integument of the Leech, by Ray Lankester; and by the same author a Memoir on the Connective and Vasifactive Tissues of the Leech. 5. On the Use of the Wenham Binocular, by Heneage Green; and by the same author a paper on the Structure of the Human Spermatozoon. 6. Some points in the Morphology of Echinoderms, by Herbert Carpenter. 7. On the Origin of the Red Blood-corpuscles, by Pouchet. And, lastly, a paper on the Limnocoedium Sowerbii, by Ray Lankester.

The economic importance of Mr. Thiselton Dyer's observations is considerable. The parasitic fungus which has devastated the coffee plantations of Ceylon and Southern India is now slowly spreading eastward through the coffee-growing countries of the Old World, and any inquiries which may lead to the discovery of the means of arresting its progress are deserving of encouragement. The pest proves to be a fungus, named by the Rev. M. J. Berkeley *Hemileia vastatrix*, the mycelium of which spreads over the leaf, destroying its vitality, and impairing consequently the productivity of the tree. The mycelium can be destroyed, and the tree saved, by the application of sulphur at an early period of the growth of the fungus. Prof. Ray Lankester's paper describes in considerable detail the singular medusa that has been found in the Victoria Regia tank of the Botanical Society's Garden, Regent's-park. It is a most active and energetic little creature, whose vigorous movements rivet attention, and it proves to be a fresh-water form, hitherto unknown, of the trachomedusæ—creatures having the genital sacs or gonads placed in the course of the radial canals.

RECENT INVESTIGATIONS ON THE ACTION OF DRUGS.

AN interesting contribution to the facts relating to the antagonism between the actions of drugs has been supplied by Pantelejeff with regard to two drugs in common use—quinine and atropine. The salts employed were the chloride of quinine and the sulphate of atropine, and the experiments were made upon dogs, rabbits, and frogs. An injection of quinine beneath the skin of a frog in summer arrests the heart in diastole; but a subsequent subcutaneous injection of atropine causes it at once to resume its pulsations. The appearance of the heart, when its action is arrested by quinine, is as if the blood-pressure on the heart was greater than the cardiac walls could contract upon. If atropine was injected first, so as to cause an acceleration, this was arrested by the quinine. With winter frogs the effect of the quinine was more frequently to cause a gradual retardation in the action of the heart, which was only arrested, after a time, with loss of reflex action, and death. The injection of atropine did not prevent this, but retarded the heart still more. Microscopic examination of the vessels of the web of the foot showed that the quinine caused a narrowing of the small arteries to one-half of their previous calibre, while atropine dilated the vessels. In rabbits it was found that when the heart's action was arrested by quinine, atropine caused it again to beat, and the auricles began to contract before the ventricles. In both dogs and rabbits the blood-pressure in the carotid rose after the injection of quinine, when the pulse was rendered less frequent. It was found that immediately after the injection the blood-pressure suddenly falls, but after a few seconds it rises to a higher degree than before the injection. In small doses the pulse is often accelerated during the increased pressure, but with large doses the pulse is retarded from the beginning. If repeated injections are made, every injection causes first a sudden fall of pressure, with retardation of the pulse; then the pressure rises, to fall again after a new injection. This initial fall in the blood-pressure is probably due to a sudden contraction of the vessels of the lungs, hindering the passage of the blood into the left ventricle and the aorta. The cardiac contractions become at the same time less frequent, but stronger. The arteries of the aortic system then contract, and cause an increase in the blood-pressure, and at the same time an acceleration of the pulse. Larger doses have a direct influence on the heart, so that, later, the cardiac action becomes retarded, and the blood-pressure falls. The pneumogastrics remain excitable by electricity, but their division exercises no marked influence upon the pulse, especially when the respiration is retarded by the action of quinine. Subsequent injection of atropine accelerates the pulse, even when the pneumogastrics have been divided. In only one observation upon dogs was an arrest of the heart by quinine prevented by atropine. The increase of pressure caused by quinine was disturbed and retarded by the preceding injection of atropine. Direct application to the heart of frogs showed that not only can quinine arrest the action of the heart, but that it can also, under certain circumstances, act as a stimulant to excite it to action, and the effect depends upon the condition in which it is.

The acute effects produced by large doses of atropine have often been studied, but the symptoms which are produced by such doses as are toxic only when long-continued have been little investigated. They have, however, lately occupied the attention of Dr. von Anrep in the physiological laboratory at Würzburg. If a dose of one to three milligrammes is administered to a dog by hypodermic injection, the slight symptoms which it causes—mydriasis, &c.—soon pass away. If the injection, however, is repeated, the effects gradually become less intense. After the fifth injection the slight modifications of the cutaneous sensibility, and the slight muscular tremors which are caused by the first doses cease to occur, the slight acceleration of the action of the heart is less marked, and the animal maintains its usual health in spite of the continued doses. Chronic poisoning with larger doses gives more persistent results. A single dose of one-twentieth of a gramme causes symptoms of acute poisoning—muscular spasm, vomiting, thirst and loss of appetite, transient acceleration of the pulse, ex-

treme dilatation of the pupil, quickened respiration, and a slight elevation of temperature. If this dose is repeated on six or ten successive days the symptoms become slighter after each injection, with the exception of the dilatation of the pupil, the acceleration of the action of the heart, and the diminution in the saliva. There is no trace of muscular spasm or tremor. After a long time the heart becomes weakened, its contractions are less frequent, being only one-half of the normal, and the effect of each new dose is to cause only a slight acceleration. From these experiments it appears that a remarkable tolerance is established to the alkaloid, even in considerable doses, so that, after a time the animals are unaffected by doses which would have been fatal at the outset of the experiments; but this tolerance is least in the case of those organs and structures which are normally the most impressionable—namely, the pupil and the pneumogastric nerve. If, after several weeks' poisoning, the administration is stopped, the heart returns to the normal condition in from three to five days. It is suggested that the *modus operandi* of atropine on the heart is as follows: The first doses act exclusively upon the pneumogastrics; the excito-motor ganglia and the muscular tissue of the heart resist the action of the poison, and are only affected by repeated doses: hence the persistence of the retardation which succeeds the initial acceleration.

The same investigator has studied the action of cocaine, the active principle of the coca-leaves. He draws the conclusion that cold-blooded animals are more sensitive to its action than warm-blooded animals. Its chief action appears to be upon the nerve-centres. In frogs, it first paralyses the terminations of the sensitive nerves, and afterwards abolishes reflex action. In the mammalia, it first stimulates all the nerve-centres, and especially the psycho-motor centres. This general excitation is followed by a slight enfeeblement. Small doses increase reflex action; large doses do not paralyse it entirely, as in the case of the frog. Respiration is quickened, except by fatal doses. In frogs the power of the heart is lessened so as to lead to arrest in diastole. In mammalia the heart's action is accelerated, and strong doses are necessary to cause a retardation. The blood-pressure is increased by the stimulation of the vaso-motor centres; large doses should naturally have the opposite action, and lower the blood-pressure. The inhibitory nerves of the heart are readily paralysed by medium doses. The striated muscles are not directly influenced by cocaine. The pupil is dilated by it, and as powerfully by the internal use of the drug as by its instillation into the eye. The peristaltic movements of the intestine are accelerated. Acute poisoning by cocaine causes muscular spasms, and, in consequence, an elevation of the rectal temperature; when there are no convulsions the rectal temperature falls. The secretion of the several mucous membranes is lessened. Certain motor disturbances can only be explained by the assumption that cocaine has an action upon the semicircular canals; the symptoms suggest that the drug modifies the pressure of the endolymph in the internal ear, and thus effects a stimulation of the terminal filaments of the auditory nerve. Death appears to result from asphyxia, caused by respiratory paralysis, the heart continuing to beat for some minutes after apparent death.

The action of cyanogen has been the subject of an experimental study by R. Bunge, at Dorpat, with frogs. He was unable to observe any convulsive phenomena, and the paralyzing effect was produced slowly, even with large doses. If the animals were examined after a few minutes' exposure to the action of the gas, the cutaneous sensibility was found to be lessened or abolished, and their movements were considerably lessened. During the first few minutes of the exposure the animals were restless from the local irritation, their movements then became slower and less frequent, the respiratory and cardiac action ceased, and rigor mortis set in with great rapidity. The latter, indeed, sometimes commenced in the hind legs while respiration was still going on. Post-mortem examination showed the heart to be dilated and filled with pale blood, in which the spectroscopic revealed the absorption bands of oxyhæmoglobin. If the blood-supply to a limb was cut off, the rigor mortis appeared in those muscles somewhat later than elsewhere. If, however, a limb was entirely separated and exposed to the action of cyanogen gas, the cadaveric rigidity rapidly appeared in it. If the heart was exposed, the ventricular contractions were seen to become less frequent and more feeble, and the irritability of the cardiac muscle to mechanical stimuli was soon lost. This was, however, preceded by a transient

acceleration of the frequency of the heart's action, which the experimenter refers to stimulation of the cardiac ganglia, or muscle substance. That it is not due to any action on the vagi is shown by the fact that, if muscarin is first applied so as to arrest the action of the heart, the stimulating effect of the cyanogen can still be observed. The chief difference between the action of cyanogen and hydrocyanic acid consists in the persistence of the respiratory movements after the heart's action has ceased, and in the early occurrence of the rigor mortis. In the mammalia, cats, rabbits, and mice, the cyanogen gas, whether inhaled or injected in watery solution into the blood, causes dyspnoea, and the animals die from respiratory paralysis, just as after poisoning with hydrocyanic acid. The blood-pressure falls, and the heart's contractions are at first rendered more frequent, but in the later stage are retarded. They continue after respiration has ceased. The toxic effect of cyanogen is less violent than that of hydrocyanic acid, .02 grm. being required to produce the same effect as .004 grm. of the latter.

THE VETERINARY DEPARTMENT OF THE PRIVY COUNCIL.

THE Annual Report of the Veterinary Department of the Privy Council, lately issued, must be pronounced, on the whole, satisfactory; in some matters unsatisfactory. It shows that, notwithstanding the opinions which at one time dominated this department, the severe scourges which have done such damage to our agriculture, and were allowed to ravage the pasture and farmstead for so many years unchecked, can be exterminated without injury or inconvenience to the general public. Since our ports were thrown open to the unrestricted importation of foreign animals, some forty years ago, exotic contagious diseases of the most destructive character have been permitted to run riot over the country, and the loss to the farmers, which means also a national loss, must have amounted to several millions of pounds annually. Much ignorance seems to have prevailed with regard to these diseases, and Government of late years appear to have only become slowly enlightened with regard to them. Their history, geographical distribution, nature, and even their transmissibility, seem to have been but little known. Hence the neglect of repressive and sanitary measures until the cattle plague visited the country, and caused such havoc in 1865. The awakening was a rude and a costly one, and a kind of system of checking that, and one or two of the other contagious diseases, was forthwith inaugurated. But it must be confessed that the Government has moved slowly, and has often indeed been a long way behind public opinion; it has had to be urged to adopt the simplest and most elementary measures, and only too often it has shown itself strangely ignorant of the prevalence and mode of combating diseases regarding which there should have been no doubt or hesitation. This was the case until 1877, when another invasion of cattle plague—quite unexpected, and therefore unprovided for—visited England. It was then somewhat roused out of its torpidity and driven into more vigorous action by the report of a Select Committee of the House of Commons, and in 1878 the Contagious Diseases (Animals) Act was passed. Since then the chief pests which had for so long wrought incalculable mischief have been gradually extinguished, though not nearly so rapidly as would have happened had the Act been properly framed and the measures energetically carried out. However, at last foot-and-mouth disease has been nearly got rid of, and contagious pleuropneumonia is greatly diminished, though far from being extinguished. It is somewhat singular that, in view of the persistency of the last-mentioned disease, the Government should ignore the benefits to be derived from protective inoculation. It is painful to read of the destruction of entire herds of cattle, only one or two of which are diseased, without this measure, the benefits of which are now placed beyond doubt, being at least tried. There is yet much torpidity, incredulity, and apathy exhibited, and we trust that the new Government may contrive to effect the removal of these barriers to improvement in this matter of contagious diseases among animals. The Act now in force is faulty in several particulars, and we shall probably have to suffer yet for many years from these disorders, unless more enlightened and efficient action is adopted.

Glanders among horses is on the increase, and the returns evidently do not represent a tithe of the cases occurring. Everything appears to be left to chance with regard to this dangerous disease; there is no compulsion in the matter of reporting the existence of the malady, nor yet any attempt to trace the source of those cases which are reported. Considering the risk human beings incur, and the loathsome and incurable character of the disorder, surely the public have a right to expect better protection from it.

From the report before us we observe it is stated that foot-and-mouth disease was detected among sheep imported from the United States; yet, strange to say, from all we can learn the disease is now unknown there. Surely a mistake has been committed.

American swine are largely infested with trichinae, yet nothing is done to protect the pork-eating public from this source of danger.

Though the report is satisfactory to some extent, yet it bears on the face of it signs of lassitude, and a tendency to allow things to go as they may. No account is taken of that terrifying and far from rare disease, rabies; nor is any mention made of anthrax—a malady of rather rare occurrence—but very fatal in different parts of the country, and being transmissible to various species of animals and man, it should, we think, secure some share of attention from the authorities. Tuberculosis of cattle, also, is unmentioned, though the disorder is rather rife, and is apparently on the increase. We wonder if the Government has heard of it, and of the recent startling disclosures made with regard to its communicability, not only by inoculation, but by ingestion of the milk and flesh of diseased cows, as well as its infectiousness through the respiratory organs! It is indeed high time something was done to keep the Government up to the level of sanitary requirements; it should lead, not follow public opinion.

STATISTICS OF FATAL CHOREA.

To the Editor of THE LANCET.

SIR,—I can add six to the eighty fatal cases of chorea brought together by Dr. Sturges in his interesting paper published in THE LANCET, July 17th. No single observer can contribute many. All my patients died of chorea, not merely with it. The cases came under my notice when I was resident physician in the Queen's Hospital. I watched them closely during life, and I examined all the bodies post mortem.

CASE 1.—Selina W—, aged fourteen years, died Nov. 30th, 1866. Death by asthenia. *Tænia mediocanellata* in small intestine.

CASE 2.—Sarah J—, aged eighteen years, died April 2nd, 1867. Death by syncope. Suffering from gonorrhoea. She was much perturbed about the venereal disease, and was very anxious to conceal it from her mother.

CASE 3.—Emily C—, aged fifteen years, died May 19th, 1868. Death by asthenia, after illness of seven days. Malady attributed to dread of destitution; she had neither relatives nor friends, and had been about to lose her situation.

CASE 4.—James N—, aged sixteen years. Died March 11th, 1870. Death by asthenia. Chorea lasted six weeks, and followed acute rheumatism. *Tænia solium* in small intestine.

CASE 5.—Emma H—, aged twelve years. Died Dec. 27th, 1870, ten days after the onset of chorea. Her illness began as acute rheumatism; when the joint affections and pyrexia were subsiding the choreic movements began. Endocardium normal.

CASE 6.—Sarah P—, aged twenty-five years. Died March 7th, 1871, by asthenia. Was delivered of a dead six-months' foetus, forty-eight hours before death; her second pregnancy. She attributed the chorea to fright and bad food.

These cases, so far as they go, support in the main Dr. Sturges' conclusions. The points worthy of note in my cases are—(1) the ages of the patients (twelve, fourteen, fifteen, sixteen, eighteen, and twenty-five years respectively); (2) the sex of the patients (five females, but only one male); (3) the association of acute rheumatism, emotional disturbance, intestinal worms, and pregnancy, with chorea.

I am, Sir, your obedient servant,

Birmingham, July 15th, 1880.

JAMES SAWYER, M.D.

THE LANCET.

LONDON: SATURDAY, JULY 31, 1880.

ANOTHER deputation has interviewed the President of the Local Government Board on the subject of the Vaccination Acts Amendment Bill, and the arguments repeatedly and ably urged against the measure have been again propounded. The novel feature of the appeal was the reading of a letter from Sir WILLIAM JENNER, which must be characterised as a singularly perfect and persuasive specimen of the *reductio ad absurdum*. After expressing an opinion that the Bill is so absurd that it is scarcely possible to conceive it will become law, Sir WILLIAM JENNER suggested:—"Instead of a fine of 20s., if Mr. DODSON determines to carry his measure would it not be better that anyone should have a licence from the Inland Revenue officer to go unvaccinated? Then one would get a licence at the same time that one got a licence for dogs, horses, &c. This certainly would be more simple, and would in time yield a revenue to the State. Licences also might be granted, for a suitable sum, for drunkenness, &c., and then people would not be fined as often as they now are 5s., I think. If a man paid 20s. at the beginning of the year he would have a season ticket for drunkenness, and a season ticket for spreading small-pox." The merit of applying this line of argument to the question may be claimed by our contemporary the *St. James's Gazette*, which adopted as a title for one of its earliest articles on the subject, "Small-pox for Forty Shillings"—in view of some recent magisterial decisions, the overture might now be made at the insignificant sum of sixpence,—but Sir WILLIAM JENNER'S use of the same weapon is more complete and convincing. If anything can kill the Bill this description of onslaught is certainly likely to be successful. The President of the Local Government Board was palpably hit, and winced. It is scarcely possible that the measure can survive, and few will mourn its decease.

Meanwhile it must not be forgotten that precisely the same confusion of thought was occasioned, and the same fears were stirred, by the proposal to reduce the penalty for stealing below the magnitude of capital punishment. It was alleged that the promoters of the relief were favouring the offence, and that by diminishing the penalty they would increase the crime. Events have not justified that anticipation. Nor do we think the erasure from the statute book of a punishment which is seldom inflicted, and never with good results, would have the effect of discouraging vaccination. If we had the smallest misgiving on that point we should join the outcry against the Bill. We yield to none in our support of vaccination. If anyone will bring in a Bill to make the Vaccination Act *directly* compulsory, it shall have our warmest support. We have gone, and still go, further than the most ardent promoters of these repeated deputations to the President of the Local Government Board, and assert the need of an Act of Parliament making *revaccination* compulsory! Nevertheless, we fail to

see the practical use—while the evil is self-evident—of maintaining a law which cannot be put into execution, for the extraction of multiple fines from the pockets of the obstinate few who decline to obey the law and to have their children vaccinated, seeing that even when the fines are enforced the children remain unvaccinated.

The Acts making vaccination compulsory have been in operation now for a considerable number of years. The machinery has been inadequate and works with a great deal of friction. The local officials in charge of the detailed application of the system have in many instances done little to assure its success. For example, it is scarcely less than a scandal that animal vaccination has been so long delayed, and it is now simply provoking to hear the President of the Local Government Board tamely stating that he has "undertaken, on behalf of the department, to give facilities for obtaining animal lymph in the same way as humanised lymph is now obtained"! When will the official mind be brought to see that sitting calmly in a chair and "giving facilities," whatever that may mean, is a miserable burlesque of business unworthy an intelligent administration, even in connexion with a "department"? It is the simple duty of the authorities acting under the supervision of the Local Government Board to *supply* the lymph, not to give "facilities" for obtaining it. If they cannot or will not do this, then it is the public and official duty of Mr. DODSON to see that it is done by some power and in some way instantly! It will be no answer to this remonstrance to say that calf lymph cannot be obtained. It *has* been possible to obtain calf lymph, and it is possible, if the "department" will act, instead of giving "facilities." Money is needed of course, but the President of the Local Government Board is now bound by the use he has made of this pledge with regard to calf lymph, in reply to the deputation, to go boldly to the Treasury and ask for the sum necessary to enable him to carry out his intentions and give the "facilities" he has promised; and the Treasury stands pledged to the country to supply the funds required. It is by the combined action of "red tape" and this policy of letting matters drift, good laws are allowed to fall into abeyance, and agencies well adapted to render excellent service in the public interest are permitted to lie idle. It is impossible to avoid a feeling of irritation as we read the feeble reply of the President of the Local Government Board to the powerful arguments brought to bear against him. He succumbed with the childish complaint that the opposition he has encountered was unexpected. If this be really the fact, it argues little for the prescience of the "department." Nothing but opposition could be encountered by such a measure. If those who framed it had been gifted with only a very moderate share of the statesmanly instinct, they would have introduced *direct* compulsion with one hand, while with the other they wiped out the blot of an impotent penalty.

The need of the moment is the substitution of an Act of Parliament making vaccination compulsory for one which practically only makes non-vaccination grievous. The policy of the latter form of enactment is not wise or far-sighted. It tends to the making of martyrs rather than enforcing the practice it enjoins. Those who respect the

law obey it for its own sake, and will obey it still; while those who assume a defiant attitude now do so with the *éclat* which results from the high price of the luxury of disobedience. We are of course speaking of the working of the law in districts where it is honestly administered, not in localities where it is levelled down to the views of the "anti-vaccinationists" by a feeble or prejudiced magistracy! If the law-breaking of the anti-vaccinationists is shorn of its financial glory as an expensive form of crime, and allowed to fall into the ranks of the contemptible offences for which the impecunious may be mulcted, we do not think the law will lose in dignity by the change. Meanwhile the questions in which we are interested, and upon which neither the arguments adduced by these deputations to the President of the Local Government Board, nor the utterances of that Minister—who, it should be remembered, is a member of the Cabinet, and in a special sense speaks and acts for the Government,—throw any light, are: What steps is it proposed to take with a view to make the observance of vaccination absolutely compulsory—an obligation of good citizenship, which can neither be avoided nor allowed to remain unfulfilled? The arguments urged against compulsory vaccination would of course have applied with equally cogent force against the law enjoining circumcision. What is good for a nation must be enforced on all its members. And what is to be done about *revaccination* and the use of lymph obtained direct from the calf? When yet another deputation waits on Mr. DODSON, perhaps these practical queries may be deemed worthy of the attention they seem to us to demand.

A MEMOIR by POUCHET which has recently appeared in the *Revue Scientifique*, and which has been translated in the current number of the *Quarterly Journal of Microscopical Science*, discusses the interesting subject of the mode of production of the red blood-corpuscles. It is not a little remarkable that the origin of the formed elements of the blood should still continue to be a matter of hypothesis, and that physiology is incapable of replying to the question, How after large losses of blood is its restoration effected? The present generation of practitioners are hardly aware of the quantity of blood that was taken from patients in acute disease by the physicians and surgeons of the past age. If works written in the early part of the present century are referred to, some surprising facts of this nature will be found. At the time when Sir W. LAWRENCE's treatise on the Venereal Diseases of the Eye was published—that is, in 1830—bleeding was the approved method of treating gonorrhœal ophthalmia; and amongst other cases he records in that work there is one of a pugilist, who was no doubt an athletic, freely-living man, but who, having contracted gonorrhœal ophthalmia, was admitted into St. Bartholomew's Hospital, and from whom the surprising quantity of one hundred and fifty-two ounces, or nearly eight pints, reckoning twenty ounces to the pint, were abstracted by venesection, besides the application of thirty-two leeches, in the short space of one week. Nor was this a solitary case, for several others are recorded in which nearly equal amounts were taken. It is worth noting that the pugilist recovered with perfect vision. In the case of women, again, enormous losses of blood are often sustained in menorrhagia,

which are yet quickly restored under favourable circumstances. RINDFLEISCH has made an estimate of the rapidity with which the reproduction of new corpuscles must take place in ordinary intermenstrual periods, and calculates that half a centigramme of blood is produced every minute, which means that about one hundred and seventy-five millions of red blood-corpuscles are produced every minute. When thus reduced to figures, it seems extraordinary that no answer can be given to the questions how and where this enormous proliferation is effected.

Is the process of renewal performed in some obscure organ whose function has been overlooked—the suprarenal capsules or thymus or thyroid gland, for example,—or is it that the corpuscles, similar as they may all appear to our methods of investigation, are derived from many different sources, each set having its own special and definite functions, and differing in structure, purpose, and destination from all the rest? The results of modern physiological research seem to point in the latter direction. Not many years ago the corpuscles were believed to be exclusively derived from the chyle, and HEWSON's observations, to which Mr. GULLIVER did good service in calling attention, were essentially in favour of the mesenteric glands being the bed for the production of the lymph corpuscles, the nuclei of which acquired colour and became the red corpuscles. More recently, however, the claims of many other parts of the body to be hæmatopoietic organs have been with more or less probability advanced, and the share of the spleen, the liver, the muscles, the cancellous tissue of the bones, and the peritoneum, in the process of blood formation, has been urged by different experimenters. Objections may, however, be raised to nearly every hypothesis that attributes the origin of the hæmatids to a single source. Even in the case of the lymphatic glands it may fairly be urged that they cannot be exclusively concerned in the generation of the red corpuscles, since such glands are wholly absent in fishes; and the same objection may be taken to the view of NEUMANN and BIZZOZERO in favour of the cancellous tissue of the bones. And granting even that they are formed here, by what means do they traverse the walls of the capillaries, and how are they impelled into the current of the circulation? The fact that the spleen is absent in some animals, as the lamprey, and may be removed even in the higher animals and man without rendering them anæmic, disposes of the idea that it does more than aid in the genesis of blood-corpuscles, and, as POUCHET remarks, little weight can be attached to the statements that a new function can be vicariously performed by other organs of a totally different structure.

In regard to the derivation of hæmatids from the lymphoid patches of the mesentery, these regions can evidently play but a small part in the production of new corpuscles. RANVIER has indeed observed hæmatids originating in the midst of vessel-forming tissue. But if this view be correct, the repair of lost blood would be necessarily associated with the production of new capillaries, which has not been demonstrated. The view which is held by M. POUCHET himself, that the real origin of the blood-corpuscles is to be looked for in the hæmatoblasts or minuter form of globules, has been described by HAYEM, and long before him by DONNÉ, under the name of globulins. These bodies pro-

bably originate in the blood plasma, being primarily formed of albumen, to which subsequently the crystalline substance hæmoglobin is added, causing a great increase in the volume of the globulets. In the blood of animals undergoing repair after large hæmorrhages, an extraordinary number of hæmatoblasts or globulets may be observed. These rapidly enlarge in all directions, lose their granular aspect, and become hyaline, and finally assume the discoid form and the yellowish tint of the full-formed corpuscle. The hæmatids are on this view neither cells nor the descendants of cells, but may, like TOPSY, be said to have simply "grewed." It would seem that the generation of the red corpuscles is still a dark corner in physiology, and some further observations are still requisite. Is not this a fit subject to be given for the Jacksonian Triennial Prize by the College of Surgeons?

THE unprecedented success of the Metropolitan Hospital Sunday Fund this year is a matter for great congratulation. Exclusive of the balance from last year, the sum raised slightly exceeds £30,000. The excess over last year's collection is nearly £5000. The Lord Mayor, Sir F. WYATT TRUSCOTT, was very properly congratulated on such a result. The entire explanation of it was not very deeply gone into at Monday's meeting. THE LANCET may fairly claim some share of credit for the result obtained. Prejudices have been broken down and information supplied. The clergy had been better supplied with facts on which to base their appeal than on any former occasion, a circumstance which should encourage the Council to a little more effort to procure and to publish information in a clear and intelligible form. Great further good would be done if the principle of distribution could be, if not simplified, classified and made more intelligible to ordinary minds. In a previous year, when there was nearly as much to distribute, the Dispensaries got nearly five hundred pounds more than they are getting under the present awards. Regarding a grant to the Eastbourne Convalescent Hospital, an institution which has never before this year applied for a grant, Dr. GLOVER inquired if the hospital were managed by a committee, as the rules of the Fund require, and was answered in the affirmative, though the committee is not mentioned in the report. Dr. GLOVER then gave the particulars of an astonishing instance in which the Sisters advised a Wesleyan patient to go to the confessional, to connect herself with a "high church" in London, and if necessary leave her family. On the motion of Sir FRANCIS LYCETT, it was unanimously agreed to postpone the grant till the above statements could be investigated. The great glory of the Hospital Sunday Fund is its catholicity—that it is raised by a combined effort of all churches, forgetful, for this high purpose, of all differences of creed. It would be a monstrous thing if, as the churches rise above all petty questions of this sort, the hospitals are to become the arenas of theological dispute and partiality. But there are not wanting indications that hospitals will be converted to this use if care be not taken.

THE death of a patient at Guy's Hospital under circumstances which have led to the committal of a nurse under a charge of manslaughter cannot but be regarded as illustrating the evils of the system of management which pre-

vails at that institution. It is not, of course, for us to say that this patient might not have died under other conditions. "Accidental," involuntary, or unconscious defecation in the recumbent posture is a well-known symptom of meningitis, especially the form known as tubercular, and it may be that the deceased died of a disease which existed *before* she was immersed in a cold bath; but that does not lessen the enormity of a system which permits a nurse to give any patient a bath on the authority of a "sister"—that palpable misnomer for a head-nurse—and without the permission of the physician in charge! The whole system of management at Guy's Hospital bristles with faults of the most astounding character. Can anything, for instance, be more ridiculous than the presumption of a lay Treasurer sitting in judgment on the conduct of a nurse, and affecting to be able to decide whether or not a particular act committed by her was "an error of judgment" or an offence? What can a layman know of the practical rules of treatment in a hospital? Again, how should a "sister" know anything of the fitness of a patient to be bathed? These women sorely need to be taught the limits of their duty, which is to *carry out the instructions of the doctors*. A trained nurse should know how to bathe a patient, but it is not for her to decide whether a bath is required or expedient. There is something radically wrong in the whole scheme carried out at Guy's and, we fear, at other hospitals. If they are to be regarded as institutions where trained nurses are allowed to "treat" cases, this should be understood. It is not tolerable that the sick poor should be induced, under a misapprehension, to entrust their lives to presumptuous and ignorant nursing "sisters," when they think they are placing themselves under the care of skilled and qualified medical practitioners. The issue raised is a very grave one. We are glad to know that it has been brought under the notice of Parliament, and we trust the consideration now bestowed on this matter will put an end to a system of hospital management and nursing, which has sprung up at too many of the hospitals in London and elsewhere, and which, apart from "cases" like this at Guy's, is nothing short of a scandal. Matters have reached a crisis, and the solution of a grave and growing question must not be deferred.

Annotations.

"No quid nimis."

THE INTERNATIONAL MEDICAL CONGRESS.

THE necessary arrangements in preparation for the seventh session of the International Medical Congress, to be held in London in August, 1881, are progressing. The committee have discussed the question of the admission of women to the meetings of the Congress, and by a decided majority have determined to issue invitations to male practitioners only. This is the decision we were confident would be arrived at, for knowing the names of the committee we felt that on this, as on other points, they fairly represented the profession, and would not take any step distasteful to the majority of their fellows. The Congress is a voluntary association, and none can claim any "right" to be asked, and the fact that on some former occasions women have, unwisely, been permitted to be present, can in no way hamper the action of the British Committee. As regards the practitioners of this

country the decision is, happily, theoretical rather than practically important.

It is now definitely announced that Her Majesty and His Royal Highness the Prince of Wales have both been graciously pleased to extend their patronage to the Congress. Some few additions have been made to the list of officers printed by us a fortnight ago. Dr. Risdon Bennett and Dr. Bucknill have been added to the list of vice-presidents, Dr. Alfred Carpenter, Mr. Erichsen, Sir H. Thompson, and Mr. G. Pollock, have been placed on the Executive Committee, and Dr. Chepmell, Mr. Mitchell Henry, M.P., and Dr. Grigg, have consented to serve on the Reception Committee. Dr. Braxton Hicks is appointed a vice-president in the Obstetric section, and Professor Curnow is a secretary of the Anatomy section. The general secretary is already able to state that many well-known and illustrious foreigners intend to be present, among others Langenbeck, Virchow, Liebreich, and Waldenburg, and there is every prospect that this meeting will be a very notable gathering of professional celebrities. It must be the aim of all British practitioners to make this session worthy of the metropolis of the world, and of the great school of British medicine and surgery. But it can only be this, if all will heartily and generously co-operate and support the Executive Committee with thorough confidence. We repeat that the composition of that committee must be accepted as satisfactory; it is not a committee of a clique, but of the whole profession, and these gentlemen certainly deserve to be treated with entire confidence in the somewhat difficult task they have undertaken. We would strongly deprecate the raising of difficulties and objections which can only have for their object the discomfiture of the committee and the impairment of the success of the Congress. No doubt it is possible to criticise adversely the selection of the committee, and the presence of some names excites surprise equalled only by that caused by the absence of others. But could we hope for a perfect list? Is it not fair to recognise the difficulty of the choice where every selection entailed a rejection of at least one equally eligible man? From those whose names do not appear at all another complete list of officers could be selected well worthy of the posts to be filled. And where there are so many to choose from, the efforts of the committee should be supported by mutual confidence and forbearance. If personal or local jealousies are to be thrust forward and the visit of the Congress is to be made the occasion for the display of party feeling, the profession in this country will be disgraced in the eyes of the whole world, and it would be well not to hold the meeting at all. We appeal with confidence to the profession to support their representatives on the Executive, and to allow them fairly and deliberately to make all arrangements free from the outside pressure that petty jealousies and party spirit, however unworthy, can always exert. Thus alone can the success of this meeting, which all must desire, be attained.

THE PARKES MUSEUM OF HYGIENE.

THE first annual meeting in connexion with this museum was held on the 27th inst., in the Egyptian Hall of the Mansion House, under the presidency of the Lord Mayor. The meeting was largely and influentially attended, and the chief magistrate was supported by Earl Fortescue, Mr. George Palmer, M.P.; Mr. Edwin Chadwick, C.B., Sir W. Jenner, K.C.B., the President of the Royal College of Surgeons, Sir Joseph Fayrer, K.C.S.I., Professor Erasmus Wilson, Mr. George Godwin, F.R.S., Mr. Rogers Field, C.E., Mr. Berkeley Hill, Mr. Gisholm Gooden, Dr. Wilson Fox, and many others.

The report, which was read by Dr. Poore, the honorary secretary, was of a decidedly encouraging character. Since

the 1st of January (the museum being open on the mornings of three days in the week) considerably over 2000 casual visitors have been registered. The demonstrations given to artisans and others during the winter were largely attended, and a letter was read from Mr. Hodgson Pratt, the chairman of the Working Men's Club and Institute Union, expressive of the great service which had been rendered to members of the institute by the practical instructions which they had received in the museum. A letter was also read from Mr. Whichcord, the president of the Institute of British Architects, stating that, though prevented by unavoidable circumstances from being present, he and his colleagues in the institute were deeply sensible of the importance of the museum. The museum is much in need of money, and the report concluded with an appeal for funds.

The first resolution, expressive of approval of the objects of the museum, was proposed by Earl Fortescue, and seconded by Mr. George Palmer, M.P. In speaking to the resolution Mr. Erichsen dwelt upon the importance of hygiene as the helpmate of the surgeon, and assured the audience that the chances of recovery of a wounded man depended more upon his sanitary or insanitary circumstances than upon the skill of the surgeon. Mr. Erasmus Wilson showed with much happiness and force (and his remarks took obviously a great hold upon the ladies present) that the much-dreaded scourge of childhood, the disease which often stopped a child's education and blighted its prospects—viz., ringworm—depended entirely upon the hygienic surroundings of the child.

Sir William Jenner, in proposing a vote of thanks to the chairman, delivered an address of singular force and interest, and Mr. George Godwin and Sir Joseph Fayrer both eloquently insisted upon the importance of sanitary knowledge to high and low, rich and poor. The meeting will, we trust, have done much to disseminate a knowledge of the importance of the Parkes Museum as a means of instruction, and there ought to be no difficulty in raising a sufficient sum to carry out the wishes of the Executive Committee—viz., "The establishment of the museum in a position more independent and more accessible than that which it at present occupies."

SICK PAUPERS.

IT is now rather more than ten years since the late Dr. Antieat our request undertook to visit the workhouses of the metropolis and report on their condition. It is therefore gratifying to us to find that the suggestions which arose out of that inquiry are gradually bearing practical fruit. The sick, the infirm, and the able-bodied paupers are, in the majority of the Metropolitan Unions, no longer huddled together in the same close confined building, situate in some filthy back-slum; but the sick are tended separately in what may be described as almost palatial infirmaries. In these, as the recent reports of our Commissioners on the Workhouse Infirmaries show, the patients are tended by trained nurses—a vast improvement on the state of affairs a few years ago. The only fault our Commissioners have as yet pointed out is that the supply of these nurses is not sufficiently liberal, and that more work is thrown on them than they can possibly perform in times of great sickness. It must not be forgotten, however, that though many of the Unions have entered on the path of reformation, many still are laggard in carrying out, or even entering upon, the much-needed reform. And here we may remark parenthetically, that it is a disgrace for a rich and wealthy parish like Marylebone to allow districts such as Stepney, Lambeth, Holborn, Westminster, and St. Giles, to pass them in the race. These parishes have for some time past provided their poor with ample accommodation in excellently-constructed sick asylums, whilst the overcrowded condition of the infirmary wards of the Maryle-

bone Workhouse during last winter and early spring can only be characterised as disgraceful. So overflowing were the wards that the guardians had to arrange with the Stepney authorities to take in patients that could not be stowed away on their own premises. It is to be hoped that the Marylebone authorities will be able to open their new buildings at Notting-hill before the commencement of next winter, so that a repetition of such overcrowding may not be experienced. Our sick paupers may congratulate themselves that the attention of the outside public is now fairly directed to them, and that the days of harsh management and neglect are rapidly passing away to be replaced by a more humane and enlightened treatment. The Association for Providing Trained Nursing in Workhouse Infirmaries, originated only a year ago by the Marchioness of Lothian, is already beginning to yield beneficial results. It is no slight thing to find that private charity is at length about to co-operate with the Poor-law machinery in relieving and sympathising with the unfortunate inmates of our parochial hospitals.

TRAIN-CATCHING.

PATERFAMILIAS, who having located his family at some "watering-place" within two or three hours of London, intends to take his holiday by "running up and down," should be warned that the practice of hurrying to catch a train is attended with many serious risks. The exertion may not be of long duration, and, except on very rare occasions, when it "seems to upset" him a little, the effort may be rapidly over and soon forgotten, but the strain on the heart and bloodvessels is violent while it lasts, and although unnoticed at the time it may work mischief. We have in our recollection cases of grave disease set up in this way, without the cognisance of the sufferer. There is, however, a class of cases, which does not appear to be generally recognised, and to which it may be well to direct attention. Not only may injury be done to the heart and great vessels by this exceptional straining, but the delicate structure of the nervous centres may be injured. It is a common experience with persons who are labouring under certain forms of incipient or subacute nervous disease, that violent exertion excites them mentally, in some instances producing almost homicidal impulses. There are several hypotheses on which this disturbance may be explained, but the point we are at the moment chiefly interested to bring out is the fact that not only may the rapid flow of blood stir the brain to impulsive action, it may even rouse dormant animal propensities to excitement. The impulse felt by a hurrying pedestrian to push or knock persons in his path is not wholly *impatience*; it is, in fact, a physically-induced irritability which, being often repeated, may become persistent. Train-catching does not improve the temper, and in some instances it may do remote and very serious mental mischief.

DEATHS IN PRISON.

THERE can be little doubt that the death of William Grant, prisoner in Walton Gaol, Lancashire, who expired suddenly from rupture of an aneurism whilst on the treadmill, will be made the subject of a searching investigation. It is to be hoped, however, that the inquiry will be conducted with fairness towards the medical officer, and that unless a case of gross carelessness can be proved against him he will not be sacrificed as a scapegoat to appease the public conscience.

Internal aneurisms are often extremely difficult to diagnose with certainty, and eminent physicians and surgeons, with all the necessary clinical appliances and opportunities of watching a case, are sometimes uncertain whether the symptoms are due to aneurism or some other cause. Again, internal aneurism may exist without giving rise to symptoms of

gravity sufficient to cause suspicion of its existence, and it is not till after the death of the patient that its presence may be detected. If, therefore, the aneurism which caused the death of the prisoner Grant belonged to this category of obscure cases no blame can possibly be attached to the medical man for overlooking its existence on the admission of the deceased. The onus of the disaster lies, as we have so frequently pointed out, in the faulty arrangements of our prison system. A man apparently healthy is passed by the medical officer, after a single examination, as fit either to undergo a period of severe starvation on bread-and-water, or to perform severe mechanical labour. He is then taken charge of by the prison officials, and his punishment commences. If the man becomes ill, he is referred to the medical officer, but there seems no provision made for watching the effect of severe punishment on the various constitutions of prisoners till the effects manifest themselves pathologically. It is probable that had the medical officer been afforded an opportunity of watching Grant at his work on the treadmill the first day of his incarceration, he might have noticed something in the respiration or action of the heart that would have roused his suspicion, and have given him some clue to the existence of the disease which was not manifest when the man was in a quiescent state. As matters at present stand, it cannot be expected that the overworked and underpaid medical officers of our gaols should be ubiquitous, nor do we fancy that too much zeal in the direction we have indicated would be received with favour by the lay officials of prisons. We are of opinion, however, that short-termed prisoners on bread-and-water diet ought to be visited at least three times daily, and the temperature taken at least once daily, so as to detect the supervention of any acute form of disease, especially that form of pneumonia which seems to be the chief cause of death among short-termed prisoners. Moreover, the medical officer should carefully watch the effect of severe mechanical work when a man is first put on the treadmill. For this purpose the existing medical staff should be considerably increased. It is right that offenders should be punished, but there we must stop. A surgeon was always present to watch the effect of the torture on prisoners in days gone by, and who cried "Hold, enough!" when the limits of physical endurance were reached. Less wise, we leave the supervision of our experimental punishments to the unskilled turnkey. The prison system has already caused some sensational deaths; but nothing is heard of those prisoners who are discharged with their health hopelessly ruined by the severe and ill-supervised discipline they have been subjected to. A committee of inquiry is urgently called for to settle this question, and we hope the investigation, when undertaken, will be thorough and impartial.

ARTICULAR CARTILAGE.

WHILE the structure and general uses of articular cartilage are easily observed and well understood, it is curious to note that one fact about it has for long puzzled anatomists. Knox wrote many years ago that the cartilage "adheres by one of its surfaces to the bony tissue in a manner as yet little understood, but extremely firm;" and the latest English author—Mr. Morris—in his recent work on the joints, says, "it is connected with bone so firmly as to seem like a continuous structure," and thus stops just short of what would appear to be the fact. Articular cartilage and the subjacent bone not only "seem like," but are "one continuous structure." Originally the whole skeleton, with but few exceptions, is cartilaginous, and the articular surfaces of bone are in most instances formed from centres of ossification deposited in masses of cartilage, which enlarge centrifugally until the whole of the cartilage, except one thin

surface, is ossified, and this remnant remains permanently as the articular cartilage. It is not, then, a union between two diverse structures, but merely that a part of a single structure has undergone a special change. The bone and cartilage are one continuous tissue, and no uniting medium can be found or expected. Similar conditions are met with in other organs and tissues; thus there is no special "union" between the general skin and the nails; nor in partial fatty degeneration of the liver do we find the fatty cells "united" in any particular fashion to the healthy ones. It is right to add that Knox objected to this view, that after removal of the lime salts from a recent bone by means of acids no intimate connexion between the tissues can be seen, and the cartilage then separates spontaneously. The explanation of this separation lies in the fact that the thin articular lamella between the cancelli and cartilage differs in many respects from ordinary bone, and especially in containing a larger proportion of earthy salts, so that when these are separated by an acid the slender animal residuum is insufficient to maintain the union of the cartilage and softened cancellous bone.

It is also worthy of note that the arrangement of the soft and firm parts of the cartilage resembles that existing in the articular ends of bones. The cells of cartilage are the soft compressible part like the medulla of bone, and the hyaline matrix is the firm resistant part analogous to the bony spicules and lamellæ. It is the custom to emphasise the arrangement of the cells in the cartilage; it is more useful and physiological to speak of the arrangement of the matrix, just as we describe the lamellæ of bone rather than the configuration of the cancelli. The matrix forms a thin pellicle on the surface of the cartilage, parallel with it, like the articular lamella of bone; this gives smoothness to the surface and welds together the deeper part, which is composed of columns arranged at right angles to the joint surface, parallel with the radiating lamellæ of the bone; between these vertical columns are the groups of soft cells. Thus the columns of matrix are arranged in the line of pressure in precisely the same way as are the lamellæ of bone. We have in this another example of the fact that articular cartilage is, if we may be excused the expression, unossified bone; and it is an error to speak of it as separate from the bone, or as something superadded to bones at their joint surfaces. By being unossified it allows the movements of bones to be noiseless, frictionless, and even, and it forms an efficient elastic spring or buffer to deaden shocks transmitted up the rigid bones.

MANCHESTER ROYAL INFIRMARY.

THE report of the Board of Management of the Manchester Royal Infirmary, presented at the annual meeting of the trustees and subscribers of the institution on the 29th inst., gives, on the whole, a satisfactory account of the work done or commenced during the past year. Sanitary defects in the building have been or are in course of being removed, and the nursing staff are to be provided with permanent accommodation in the grounds. The increase in the number of patients treated has not, it would appear from the balance-sheet, been attended with an augmented expenditure, the disbursements having been less, indeed, than in the previous year, and this economy has not, the Board state, been effected at the expense of efficiency. Whilst the Convalescent Hospital at Cheadle has been worked to its full capacity, the hospital at Monsall has, considering the extent of its accommodation, and owing to the general absence of infectious disease, been comparatively empty, the number of beds occupied during the year having averaged only twenty-one. The yearly expenditure at the three institutions is estimated at about £27,000; the income last year was £20,803, and the legacies amounted to £715.

COLOUR-BLINDNESS AND RAILWAY EMPLOYEES.

THE State of Connecticut has set an example in the matter of colour-blindness among railway employes which is worthy of imitation. An Act has there recently been passed which imposes the duty upon every railway company to have each person in their employ as "locomotive engineer or fireman, train conductor or brakeman, station agent, switchman, flagman, gate-tender, or signalman," examined, on or before the first day of October next, by one of the examiners to be appointed by the Governor of the State, as to colour-blindness and visual power. It is further enacted that every railway employing a person in any of the specified capacities who does not possess a certificate of freedom from colour-blindness, and possession of visual power, duly issued in accordance with the provisions of the Act, shall be punished by a fine of not less than 200, and not more than 1000, dollars. The duty and responsibility of carrying out the provisions of this Act have been delegated to the State Board of Health. Rules and regulations in accordance with the Act have been drawn up, and have doubtless been placed in the hands of every company owning or working a railway within the State. It is provided that this Board shall annually, in the month of May, recommend to the Governor, for appointment as examiners, two or more medical experts; such examiners to issue certificates in accordance with the Rules of the Board of Health, and to report to the Board. The State of Connecticut is the first of the American States to pass a law requiring the examination of all persons employed in moving railway trains, and it is reported that the standards adopted for the examinations are, for the most part, those agreed upon at the International Medical Congress at Amsterdam, in September, 1879. The extensive prevalence of colour-blindness, which has recently attracted considerable attention, and the almost universal use of colour-signals on railways, make the adoption of some such legislative action on our home railways almost a necessity.

HYDROPHOBIA.

FROM Lancashire, Cheshire, and Wales accounts reach us of renewed attacks of hydrophobia. A man, aged twenty-one, has died of the disease in the Manchester Infirmary, who had been bitten by a dog fourteen months ago. The animal was "running" some sheep, and the man pursued it to a hole, in which it took refuge. In trying to pull it out the dog bit him on the hand. At Prestwich several cases of rabies have occurred. One of the dogs has bitten three children, and, it is said, has not been destroyed. We learn from the *Bristol Mercury* that the village of Bodlinog, in the Rhymney Valley, was lately thrown into a state of great excitement by the appearance of a rabid hound which tore through the streets, biting everything that came in its way in the most savage manner. On being chased from the village, the animal flew across the mountain to Deri, and flew at some children, and savagely attacked a dog and a cat. Farther on it bit a boy in the ear, and a man in the calf, and then so injured a little boy that his life is in a precarious condition. At least twenty dogs known to have been bitten were destroyed. Several persons have been warned to watch other animals which it is feared have been bitten, and steps have been taken at other villages, through which the dog passed, to guard against other tainted or suspected animals being at large. Had a similar precaution been taken in the case of the affected hound this disastrous outbreak would not have occurred. The dog belonged to a farmer in the neighbourhood, and is known to have been bitten three months ago. Surely the owner of a dog, under such circumstances, should be held responsible for the results of not destroying it, and, still worse, of allowing it to be at large.

PROPOSED TESTIMONIAL TO PROFESSOR SPENCE.

ABOUT six weeks ago some professional friends of Professor Spence proposed that, in consideration of the distinguished services he had rendered to surgical science, the profession should present him with his portrait, and also that a replica should be placed in the hall of the Royal College of Surgeons, Edinburgh. This proposal has been so cordially supported that with a few additional subscriptions the Committee hope to be able to present each subscriber with an etching of the portrait by Durand of Paris. The list will remain open for another month, in order to give to those who may not have heard of the movement an opportunity of contributing. The subscriptions are limited to one guinea, and are payable to Dr. P. H. Maclaren, the Honorary Secretary and Treasurer.

DR. TANNER.

DR. TANNER continues his voluntary fast at New York. Opinions are much divided as to the absolute integrity of the fast, but, if the reports are true, there can be no question that the nearest limit to actual starvation is attained. When the case is complete we shall see whether any physiological lessons have been learned; at present we have no reason to congratulate ourselves on any important gain to science through this fool-hardy experiment.

THE members of our profession, whose names are published in connexion with the sad affair at Candahar, are as follows:—Dr. Harvey, who brought news of the battery; Surgeon-Major C. J. F. McDowall, 3rd Bombay Cavalry; Surgeon G. E. E. Burroughs, 3rd Scinde Horse; Surgeon-Major C. J. Sylvester, and Surgeon A. K. Stewart, 1st Bombay N. I.; Surgeon E. Toftell, 30th Bombay N. I.; Brigade-Surgeon J. O'Nial, Principal Medical Officer with General Primrose's force.

WE are requested to announce that the full-sized clay model of the statue of Harvey, which is to be erected at Folkestone, has nearly approached completion, and that the sculptor, Mr. A. B. Joy, invites the subscribers to the Harvey Tercentenary Memorial Fund to a private view of the model (upon presentation of address cards) on Wednesday next, the 4th of August, from 11 to 5.30 P.M., at his studio, No. 8, The Avenue, 76, Fulham-road, S.W.

THE election to the surgeoncy of the Cumberland Infirmary, recently held by Dr. Macdonnell, appears to be exciting considerable interest in the northern county. The names of two gentlemen are mentioned as candidates for this appointment—Dr. H. A. Lediard, F.R.C.S. Eng., and Mr. W. Brown, M.R.C.S. Eng., L.R.C.P. Edin.

THE General Committee of the Chelmsford Dispensary and Infirmary are contemplating the purchase of a site on which to erect a more commodious building for the accommodation of the patients of the institutions, and are making arrangements for the collection of funds for the purpose.

ACCORDING to the *Times of India* of last mail, the European troops stationed at Mhow, in the Bombay Presidency, are suffering from malarial and sun fevers of a very severe type. The heat of the weather had been for some months unusually severe.

WE are asked to announce that the annual meeting of the Irish Medical Graduates' Association will be held in the Section room at Cambridge on Wednesday, August 11th, at 5.30 P.M. The annual dinner will take place at the Lion Hotel, at 6.30.

It is feared that Dr. Haller, a physician of Burgdorf, who, with guides, left Grindelwald on July 14th for the Bergh Hut, and has not since been heard of, has perished in his attempted ascent of the Matterhorn.

MR. ARTHUR STANLEY BUTLER, of Exeter College, Oxford, has been chosen to fill the chair of Natural Philosophy in St. Andrews University, recently vacated by Dr. William Swan.

DR. MATTHEWS DUNCAN has accepted the invitation of the Council of the Midland Medical Society to deliver the inaugural address for the ensuing session.

A SUM of £80,000 has been ensured for the purpose of promoting the movement for establishing a University College in Liverpool.

THE approaching meeting of the Social Science Congress in Edinburgh will be presided over by Lord Reay.

The Lancet Commission ON WORKHOUSE INFIRMARIES.

LIVERPOOL.

BEFORE entering into a detailed description of sick asylums as distinct from the workhouse proper, we think for the sake of contrast it will be advisable to present our readers with a picture of a large workhouse in which the sick, the infirm, and able-bodied are still treated in the same establishment. And for this purpose the Liverpool Workhouse affords a striking illustration. For whilst it exhibits markedly the disadvantages of the combined system, it shows how careful management can lessen the difficulties and evils inseparable from such an arrangement.

The Liverpool Workhouse stands on an elevated piece of ground centrally situated in one of the best quarters of Liverpool, closely adjacent to the School of Medicine and the Royal Infirmary, and consists of three main blocks of buildings. A central block which contains the principal offices of the establishment, the receiving rooms for new inmates and urgent cases, clerks' offices, dining-hall for the able-bodied inmates, kitchen, bakery, stores, dispensary, &c. Persons wishing to become acquainted with the details of management connected with such large establishments could not do better than pay a visit to this department. The house governor, Mr. Anderson, evidently prides himself on his arrangements, and certainly he deserves considerable praise for the scrupulous order and cleanliness that are everywhere manifest in this part of the building. The stores, too, seem to have been selected with considerable judgment, and the meat, flour, coffee, cocoa, &c., which we examined, were of excellent quality. The dining-hall was filled with inmates at the time of our visit, who were just finishing dinner, which that day consisted of "scouse," a dish the composition of which will be best described to the uninitiated as a kind of Irish stew rubbed down to a mash. It tasted to us appetising, and its constituents were certainly eminently nutritious, and it seemed, to judge from the polished empty basins, to find favour with the diners, many of whom looked, like Oliver Twist, ready to ask "for more." The vast assemblage of worn, expressionless, aged faces in this hall, struck us most painfully. A representation of some of them would form a fitting companion to Herkomer's picture, "The Last Muster," only in this case the veterans depicted would be those who had always fought in a battle that had always been against them.

The central block may be said to be flanked by two lateral blocks, one consisting of the buildings set aside for the male inmates and a separate building for fever cases; the other

for female inmates; and for the purpose of description, the chapel may be considered to belong to this block. These lateral blocks being (with the exception of the detached building devoted to fever cases, and the chapel) old ones, they therefore lack much of the convenience and suitability for hospital purposes which obtain in the admirably planned modern infirmaries which have been, and are being, established in the metropolis. The total number of inmates the workhouse is capable of containing is 3500. On the day of our visit they numbered 2840—of whom 1412, or about one-half, were in hospital. The average daily number in the sick wards is 936, about one-third being acute cases; whilst the daily average in the infirm wards is 430—"all of them chronic and mostly helpless cases, requiring constant nursing with but little medical treatment." The number of admissions into the hospital wards during the year is about 10,000; and last year there were 1178 deaths. The medical staff consists of three non-resident officers—viz., Drs. Gee, Alexander, and Robertson, who make daily visits; and a resident staff of three medical officers—a number generally increased to four in the winter, when the stress of work is greatest. The nursing department is under the control of a lady-superintendent, and is conducted on the Nightingale system. The nursing staff comprises 59 day and 16 night-nurses all told, inclusive of 10 nurses attached to the fever block, and 27 probationer nurses. The resources of the institution are wisely devoted to the training of nurses, many of whom leave the infirmary highly qualified to take up work in hospitals and elsewhere.

The wards vary much in size and disposition. The male wards occupy one side of the quadrangle, the female another side. Some of the wards are much better adapted for their purpose than others; are commodious and well lighted; others are shut off on one side by a corridor, with wards opening on each landing. The wards on the female side are less commodious than those on the male side of the house. The number of beds in each ward varies from twenty-six to fourteen, but some few of the wards are double. We were struck by the manner in which every available space was occupied by the wards; on some floors they opened directly one into another, and in this respect the building is at a great disadvantage. As to the disposition of the wards and their assignment to particular classes of cases, we can only speak in very general terms; for although we had the advantage of being shown over the whole of the buildings by the medical staff and Mr. Anderson, the governor, the number and variety of the wards make it impossible for us here to do more than speak in very general terms upon their disposition. In the basement are the lunatic wards, suitably provided with padded rooms. The insane have only a temporary lodgment in the workhouse pending their removal to the county asylum. The wards are disposed on three floors. Of these the first is devoted mainly to medical cases, the second to surgical, and the third to infirm and dirty cases. Of these latter there were no fewer than 179 on the male side, and 249 on the female, on the day of our visit. A decided improvement in these infirm wards is the substitution of iron bedsteads, one side of which can be let down, and furnished with mattresses made in two segments, in place of the old wooden, trough-shaped bed, sloping to a central aperture. Many of these old beds are still in use; but the governor hopes in time to get them all changed for the improved bedstead. The cases of ulcer are collected into one ward, and many different methods are from time to time tried in this treatment. Lately Dr. Alexander has been using hydrochloric acid dressings with good results. The eye-wards contained several cases of ophthalmia, but by no means an excessive amount. There is a special ward for erysipelas cases; but we are informed that no cases of erysipelas have arisen in the hospital in the last three years; nor has there been any pyæmia to speak of, an immunity which is attributed to the free use of disinfectants. Then there are special Lock wards, and cleansing wards for the reception of cases of scabies. These latter are generally very full of inmates, and it is found to be a matter of difficulty to get the bedding thoroughly looked after. The lying-in wards are fairly well arranged, and during last year received about three hundred inmates. Patients coming for admission are, if urgent cases, seen at once; but other cases are kept at the receiving ward until 5 P.M. There are large baths, and also provision made for disinfecting and destroying clothes. The majority of cases admitted are, as may be expected, chronic in nature—bronchitis, phthisis, heart disease, rheumatism, and paralysis. We cannot give any

statistics on this point, no published medical report being issued, so far as we are aware. Still there is, of course, a fair sprinkling of acute diseases—pneumonia, acute rheumatism, &c.—whilst all fever cases are admitted into the separate building set aside for their reception. It may be convenient if we now at this time record our impression of the nature and variety of disease included in these walls. We fully admit that it is rich in most valuable clinical material, which has frequently been set to good advantage by the medical officers. We were shown several cases of paralysis agitans—of different degrees—one of the most striking being that of an old-looking, semi-imbecile man, forty years of age, who has been in the infirmary for twenty-two years, and who is now quite unable to move about. Two well-marked cases of progressive muscular atrophy—one in a man of sixty-two—were pointed out as being good examples of this affection, and in the infirm wards of both sexes there is congregated a large number of hemiplegics, paraplegics, and ataxics. An excellent example of molluscum fibrosum, another of ichthyosis hystrix, and one of elephantiasis Græcorum, were also to be found in the male wards. The leprosy case was especially interesting. The patient was forty-two years of age, and had suffered from the disease for about two years. He presented the well-marked leonine type of features, and we were informed that very great improvement had taken place in him under the use of chaulmoogra oil. Amongst the surgical cases was one of amputation of the hip for disease in a boy. The case was doing very well. Another case was one in which Dr. Alexander had performed two operations for epithelioma of the lip. These are only a very few out of the many cases of interest contained in the infirmary; there enumeration will suffice to show that there is no lack of material for clinical observation or surgical operation. The means at the disposal of the staff for keeping records of the cases did not appear to us to be very complete. There do not seem to be any case-papers distinct from those employed for entering the prescriptions. The temperatures are taken by the nurses, who are provided with thermometers for the purpose; in acute cases such records are made twice a day, but no special charts are provided. The testing of the urine also falls to the nurses; in every case this is done on admission, but apparently not subsequently unless the urine is then shown to be abnormal. In the nurse's room attached to the wards are stored such medical appliances as cupping instruments, croup-kettles, ophthalmoscopes, and urine-testing apparatus; whilst in the same room are stocked a considerable number of drugs supplied from the dispensary. The medicines of each patient are all stored in one cupboard in the ward, and not placed by the bedside. The poisons are kept apart—a wise and necessary precaution. The fever hospital, which is wholly detached from the rest of the buildings, contains 160 beds, and it is interesting to recall that it stands on the site of the old fever buildings where Currie practised his treatment of fever by cold bathing—a treatment which, after falling into unmerited oblivion in this country, has at length been widely revived. Many of the cases admitted into these fever wards came from the ships of the port, and on the day of our visit we saw a Swedish woman with her child suffering from varicella in one of the wards on the ground-floor, these two wards being devoted usually to pyrexial cases of an indefinite character. In one of the upper wards were some members of a family suffering from typhus. But of late years fever has diminished very much in Liverpool, and beyond the cases mentioned the fever block was empty. The resident officers take it in turn to look after this department, which has a nursing staff distinct from the rest of the building. There are two institutions affiliated to the workhouse which should not be passed over. One is a convalescent hospital at Maghill for about forty cases, mostly children; the other an imbecile asylum at Dingle Mount for about ninety harmless imbeciles, idiots, and epileptics. Each of these institutions is visited daily by a specially-appointed medical officer, one of the local practitioners of the district. They are in charge of female officers, but are in every way, as regards administration, worked from the workhouse. The mortuary arrangements struck us as being unsatisfactory. The dead-house and post-mortem room are decidedly cramped, and situated too near the general buildings either for health or decency. This and the crowded condition of the sick wards struck us as the most objectionable features noticed in our round of inspection.

The general impression our visit made upon us was that

this infirmary is decidedly well managed, and, in spite of disadvantages arising from its primary faults of construction, is well worthy of the high position it takes amongst these institutions in the provinces. It abounds in much valuable clinical material, and is fortunate in possessing a staff who largely avail themselves of the opportunities afforded them, and who work zealously in the spirit of the age. At the same time we believe that these gentlemen would be the first to welcome any suggestions whereby the study and observation of these cases could be made available to others. If it were possible to institute minor officials to record the cases, all this valuable material would be put to good purpose. It would be even worth the while of advanced students to spend some months within the wards of such an institution as this, containing as they do so varied a group of examples of disease,—especially rich in the diseases of old age. But if there be one direction more than another in which the Liverpool Workhouse Infirmary should be commended, it is in its nursing system. We are far from saying that even yet is its nursing staff sufficient to cope with the vast amount of labour entailed on it, especially in the crowded infirm wards. Still it is always possible to increase a staff, the great thing is to have a sound and good working system. The revolution effected in workhouse nursing, since Agnes Jones was appointed the first superintendent to establish a system of trained nursing, was one which began in Liverpool, to spread thence over the land. The experiment proved to be a success, a result in a large measure no doubt owing to the indefatigable labours of that excellent lady, whose "Memorials" contrast in their simplicity with one other biography of a similar kind, recently published and far more widely read. Those who knew Miss Jones have testified in no measured language to her worth, and her premature death from typhus, contracted in the discharge of her duties, was deeply deplored. In the few years of responsible position at the Liverpool Infirmary she succeeded in establishing a system of nursing which has never been called in question, and which it would be well for some present-day reformers to imitate instead of creating impracticable systems of their own.

The separation of the sick from the ordinary infirm and able-bodied pauper would greatly facilitate and ensure the proper treatment of the sick. And it seems to us a question well worth the serious consideration of the guardians whether the construction of the buildings on another site in some other quarter might not be possible to obtain this advantage. The present site must be of considerable value, and the sale of it might enable the guardians to erect a more commodious building on cheaper land in the suburbs. The majority of cases could then be housed and treated in better buildings and purer air than is at present the case; whilst it would be only necessary to retain a comparatively small building in the city for the reception of casual inmates and acute cases of illness arising among the outside population. The ratepayers of Liverpool, are not only shrewd men of business, but have shown considerable liberality in many matters concerning the welfare of the poor of their town, so that the consideration of slight temporary increase in the rates caused by the removal would probably not deter them if they felt convinced it was the right thing to do. Of that we have no doubt, and believe the question of removal of some of the inmates to more spacious quarters to be one only of time. The Liverpool guardians have earned the credit of being the first to introduce the system of trained nursing in our workhouse infirmaries, one of their number, Mr. Rathbone, guaranteeing a large sum, £5000 we believe, to cover expenses in case the experiment failed. With such an instance of Liverpool munificence and liberality before us, we shall be surprised if the guardians of that city will long remain content with their present crowded and unsuitable building, but will ere long vie with London and their neighbour, Manchester, in erecting a new workhouse and sick asylum adequate to the increasing requirements of the city, and worthy of themselves.

A GOLD CUP and an appreciative address were in the early part of last month presented, at the hall of the Medical Society of Victoria, to Dr. J. E. Neild, who for many years has occupied the posts of editor of the *Australian Medical Journal* and secretary to the Society. The meeting at which the presentation took place was attended by a large number of the leading medical men of Victoria, and appears to have been of a very gratifying character to all present.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Southend.—Our readers will probably remember that at the close of the past year and the beginning of the present rumours of a serious prevalence of enteric fever in the pleasant seaside resort of Southend, situated on the northern shore of the estuary of the Thames, became current. The rumours appeared to derive confirmation when it became known that Dr. Thorne Thorne, of the medical department of the Local Government Board, had been despatched to the spot with instructions to make inquiry as to the rumoured fever, and generally to examine the sanitary condition of Southend. Dr. Thorne Thorne's report of this investigation is now before us, and we may say at once that while the rumours of fever proved to be well-founded, the locality in which the disease appeared was not the town of Southend—the health-resort of that name—but a detached hamlet, named Prittlewell, within the urban sanitary district of Southend. The town, in fact, escaped the outbreak of fever, and does not appear to have suffered from the contiguity of the infected locality. "Indeed," writes Dr. Thorne, "the two places (Prittlewell and Southend) are, from a sanitary point of view, quite distinct; they are situated about a mile apart; they have different water supplies and distinct methods of drainage; and there appear to be no direct means by which such a disease as enteric fever could spread from one to the other." The sanitary condition of the town of Southend seems to be fairly attended to by the local authority. There is an excellent public water-supply, but this is not yet generally distributed; and a system of sewerage, which needs some details before it will be completed. But if the local authority think fit to be guided by Dr. Thorne's recommendations, it may readily place the sanitary reputation of Southend beyond reproach.

Prittlewell, the scene of the outbreak of fever, is an ancient detached village within the Southend urban sanitary district, and at the time of Dr. Thorne's inquiry seems to have been wholly neglected by the sanitary authority. Here during the six months, September, 1879, and February, 1880, among a population estimated at 600, no less than 100 cases of enteric fever occurred. Wells, cesspools, and privy-pits are hollowed promiscuously in the same porous stratum of subsoil. The wells are at all times liable to pollution by percolation of the contents of the cesspools and privy-pits through the intervening soil; but this liability is much greater at some times than others. Thus, for instance, when the level of the subsoil water becomes exceptionally raised after heavy rainfall, and encroaches upon the cesspools and privy-pits, the water in the wells and the filth in the cesspools and privy-pits are put in direct communication. This condition of things, it appears, happened in Prittlewell in the autumn of 1878; it was not general over the whole of the village, but from a topographical peculiarity was confined to a particular portion of it. It was to this portion that the outbreak of enteric fever was almost wholly confined; and there can be little doubt that the disease was then determined by an exceptionally polluted state of the water-supply of the particular locality. The prosperity of Southend town must run risk of being seriously damaged by a continuance of the state of things, both as to water-supply and drainage, which Dr. Thorne describes he found in Prittlewell; and as the village, by extension of buildings in that direction, appears to be about to become a part of the town, it behoves the local authority to amend as quickly as possible the sanitary condition of the village, and remove a reproach from their district.

Edmonton.—A report has been issued by the Local Government Board, containing the results of an inquiry made by Dr. H. F. Parsons, one of their medical inspectors, on the results of an inquiry into the endemic prevalence of enteric fever and the general sanitary condition of the urban sanitary district of Edmonton, in the northern suburbs of London. The report presents a remarkable picture of the

sanitary and structural conditions of buildings which too commonly obtain in the rapidly-extending suburbs of London, where apathetic and short-sighted local authorities and imperfect bye-laws contribute to reproduce year after year the evils which it has been the aim of the sanitary Acts to obviate. "The cottages recently erected in Edmonton proper," writes Dr. Parsons, "are many of them of the flimsiest style of jerry-building. The mortar which was being used at the time of the inquiry in some cottages in course of erection mainly consisted of road scrapings—black fetid sludge. The sanitary authority had, however, legal proceedings pending against a builder for using improper materials for mortar. There was no damp-course in many instances. In one case there were no ridge-tiles to the roof to exclude rain, the slates at the angle of the roof being merely nailed by their edge to the ridge piece." This being an example of the state of matters above-ground with regard to the most numerous class of buildings, the sort of care given to those matters which are hidden from sight below ground may readily be conceived. Edmonton has a system of sewers, but these appear to have been constructed after the manner of the cottages described, and it seems questionable whether they are more mischievous or useful. Of house drainage (the public sewers being as hinted), it may be said that its main aim seems to be not to facilitate the passage of drainage into the sewers, but to facilitate its leakage into the subsoil. Cesspools and privies are still common, the system of sewerage notwithstanding. Add that almost all the water supply is derived from shallow wells, and the mind is at no loss to conceive the conditions which make enteric fever endemic in the place. Indeed, the insanitary arrangements of Edmonton appear to be especially designed for facilitating the pollution of the soil, the water, and the air with the excremental matter. Dr. Parsons mentions a curious indication of fouling of the soil which we have not found noted before. In certain cottages, especially on Sundays, an offensive effluvia pervades the house, coming from the coal-cellars. In these cases the floor of the cellar proved to be the natural soil, unfloored with wood or other material. On Sundays pumping at the outlet of the sewers, for the purpose of distributing the sewage on to land for irrigation ceases, and the sewage backs up in the sewers, and consequently, having regard to their leakiness, in the subsoil. This effluvia is chiefly observed coincidentally with this backing-up of the sewage, and Dr. Parsons is no doubt right in looking upon it as an indication of the weekly surcharging of the subsoil with offensive matters.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Leicester.—Dr. W. Johnston's report on the health and sanitary condition of the borough of Leicester for the year 1879 is, like previous reports of this gentleman, a document of the highest interest. Although dealing with strictly local subjects, it treats them in a fashion which gives them general value, and makes the report one of permanent importance. It is not an insignificant consideration that the report is published with a careful consideration to typography and diagrammatic illustration, which add to its interest and befit its worth. The subjects which will chiefly arrest attention in this report relate to the working of the local Act requiring the giving immediate information to the sanitary authority of the occurrence of certain diseases, the observations on diarrhoea, the immunity of Leicester from "fever," and the infant mortality of the place. The local Act referred to came into operation on Sept. 13th, 1879. Nevertheless, short as the period was within which the Act had been in force, Dr. Johnston reports very favourably of the advantages in the limitation of infectious disease which had been derived from it. A larger number of cases had been removed to hospital; it had been possible to maintain a greater control over children from infected houses or convalescent from infectious disease frequenting school, as well as over the making up of goods for commercial purposes in infected houses, and more detailed care in helping families as to processes of disinfection had become practicable. The Act, notwithstanding predictions to the contrary, has worked without friction, and Dr. Johnston is obviously hopeful that the antagonism to the Act displayed in the first instance by the medical profession in the borough will subside. The marked success of operation of the Leicester Act no doubt rests largely on the fact that the borough possessed at the time the Act came into force an excellent infectious-disease hospital. The possession of such a hospital ought to be made

a condition precedent to the granting of powers to any sanitary authority for the compulsory communication of information as to infectious disease. The death-rate from diarrhoea in Leicester in 1879 was the lowest that had been recorded in that town. Dr. Johnston comments on this concurrence of a low death-rate with the low average of mean temperature of the air, the absence of sunshine, and the great rainfall, and shows how the facts tend to confirm the conclusions he has formed on the influence of ferments derived from the putrefaction of animal refuse collected in cesspools and sewers in provoking diarrhoea. He again points out from last year's records that the diarrhoea was not limited to any particular age, although chiefly fatal in infants and young children—a distribution inconsistent with the view that diarrhoea was the result of maternal neglect and bad nursing. The immunity from fever in Leicester is assigned to the general plan of avoiding direct connexion between the house-drains and the sewer, the rarity of cesspools, the absence of "slums," and the good supply of pure water. Dr. Johnston discusses at some length the causes of the excessive infant mortality of Leicester, and shows that this mortality is especially a phenomenon of the third quarter of the year, and particularly relates to diarrhoea, tubercular diseases, atrophic affections, and premature birth. A theory of maternal neglect is wholly insufficient to account for the phenomenon, and to whatever extent such neglect may concur in helping to the result, other and more efficient causes must be sought for an explanation. These causes, in so far as diarrhoea is concerned, must, according to Dr. Johnston, be looked for in peculiar local conditions.

Bolton.—Mr. Edward Sergeant has had the good fortune of having to prepare for his sanitary authority a quite uneventful report of the health and sanitary condition of his district for the year 1879. The borough in that year had a birth-rate of 37·0 per 1000 proper and a death-rate of 21·2 per 1000. The infant mortality was unusually low, and zymotic diseases "were accredited with fewer deaths than in any year yet recorded." Nevertheless, Mr. Sergeant has sought to attach a special interest to his present report by giving (after the manner of Mr. T. P. Teale) plates illustrative of the dangers arising from sundry defective drainage arrangements. The report has some observations on the second year's operation of the Local Act for the notification of infectious diseases to the Sanitary Authority. The Act, in the first instance, worked with so much friction that it was found necessary last year to obtain a Provisional Order for amending it in several details. We fail to gather from the present report a clear idea of the working of the Act as amended by the Provisional Order, but it seems doubtful whether friction has still been satisfactorily removed. The amount of infectious sickness reported to the Sanitary Authority last year (651 cases) was less than in the previous year, but, happily, this is to be attributed to the exceptional freedom of the town from infectious diseases.

REPORT OF THE MEDICAL SUPERINTENDENT OF THE DEPTFORD HOSPITAL.

The report of the Medical Superintendent of the Deptford Hospital (Dr. John McCombie) for 1879 shows that, in the course of the year, 1634 acute cases of small-pox were admitted, 1325 discharged recovered, and 282 died. Of these cases 1148 were vaccinated, of 228 the vaccination was doubtful, and 258 unvaccinated. Of the vaccinated 83 died, of the doubtfully vaccinated 78, and of the unvaccinated 121, showing a death-rate of 7·2 per cent. in the vaccinated, 34·6 per cent. in the doubtfully vaccinated, and 47·2 per cent. for the unvaccinated. The statistics Dr. McCombie gives suggest to him that sex appears to have an important influence on the mortality from small-pox in vaccinated persons after puberty. They show that in cases with imperfect marks two deaths occur in females as early as seven years, while in males no death occurs before twelve; and in cases with good marks deaths occur in females at eleven years of age, and there are five deaths under puberty (sixteen years); but in males no death occurs under nineteen years. He thinks that these data indicate the necessity for earlier revaccination in the case of females than in the case of males.

Dr. McCombie records not less than ten cases of small-pox after revaccination; but on these cases he observes—"It would appear from this that cases of small-pox do occasionally occur after apparently successful revaccination; but I

would remark that in nearly all the cases the primary vaccination was imperfect, and I would suggest that the revaccination was in some way imperfect, since no case of small-pox has occurred here among the staff, who were successfully revaccinated before entering on their duties. Up to Dec. 31st, 1879, 148 staff have been employed in the hospital. Of these, 141 have been in more or less direct contact with patients suffering from small-pox. All were revaccinated before entering on their duties; only one took small-pox. This was the case of a ward servant, who developed small-pox after entering the service, and eight days after revaccination had been performed. She had evidently received the infection of small-pox before she was revaccinated."

THE HEREFORD SANITARY COMBINATION.

We learn from the *Hereford Times* that the authorities of the Hereford Combined Sanitary District have decided to maintain their combination, at least for a further period of three years, and to retain Dr. Vavasour Sandford in the appointment of Medical Officer of Health, an appointment which he has now held for six years. The right-mindedness of this action is, however, stultified by a resolution of the authorities to reduce the salary of the medical officer of health from £550 to £400! It is admitted by the authorities, without exception, that Dr. Vavasour Sandford has done the duties of his difficult office well, and with infinite advantage to the sanitary condition of the combined districts; moreover, that at least £100 of the proposed salary must be devoted to travelling expenses. Fortunately, the resolution of the authorities cannot be carried into effect without the consent of the Local Government Board, and we can scarcely conceive of that Board lending itself to a procedure which is calculated to degrade the functions of a medical officer of health, and to deter men of good standing and with the requisite qualifications from holding the post. It is high time that some measures were taken to put an end to these vagaries of local sanitary authorities. They betray on the part of the perpetrators an indifference to public-health requirements of communities under their care, and a disposition to behave unjustly to medical officers of health, in the highest degree disheartening, and it behoves the Local Government Board to see that the designs of the Legislature shall not be frustrated in this pitiful fashion.

THE WATER-SUPPLY OF CROMER.

A seaside town, with waterclosets and a system of drainage into the sea, and no regular water-supply, must be regarded as in a very unsafe sanitary condition. These are the conditions which obtain in the charming little Norfolk resort—Cromer. A project for establishing an adequate water-supply has been for some time in progress, but it has lately hung fire, and there is some fear that it may be relinquished. At present the chief source of water for ordinary purpose is the rain. There are a few wells in the town, water from which can be purchased, but for the watercloset-supply, cleanliness, and even in many cases for drinking purposes, rain-water is used, collected in large tanks. No doubt, in a wet season, such as the present, the supply is adequate, but in a dry season the supply may fail, and the state of affairs would then be perilous in the extreme. Perfect waterclosets, an abundant water-supply, and free ventilation of the sewers are absolutely essential for the safety of a system of drainage into the sea, and if anyone of these conditions is imperfect the sanitary system becomes insanitary, and the provision for health, a source of disease. It behoves those who are interested in the town to persevere in their efforts to establish a good water-supply, or public confidence in the salubrity of the place will scarcely be maintained.

REGISTRATION OF INFECTIOUS DISEASES.

At a meeting of the Executive Committee of the Dublin Sanitary Association, held recently, a resolution was adopted in reference to this subject. The committee approved generally of the principle involved in the proposal to establish a system of early and compulsory notification of infectious diseases to the Sanitary Authority, and of subsequent official registration of the same, as they believe that the information so obtained as to the origin and spread of epidemic diseases cannot fail to be of great value in aid of the efforts to improve public health.

THE RIVERS POLLUTION PREVENTION ACT.

A deputation from the Fisheries Preservation and other Associations had an interview with the President of the Local Government Board on Tuesday, the 27th, for the purpose of representing to him the necessity which, from their point of view, existed for giving greater facilities for putting the Rivers Pollution Prevention Act, 1876, in operation, and for making its provisions more stringent. Mr. Dodson, in reply, stated in effect that the observations of the deputation furnished another illustration of the difficulties surrounding the subject of purifying our rivers. Government was called upon to reconcile in the best way they could the commercial, fishery, and sanitary interests involved in the question, each clashing with the others. The subject was one on which he could not give an answer on the part of the Government on that occasion, but the observations of the deputation would receive his most careful attention.

SANITARY CONDITION OF THE NORTH DUBLIN UNION.

Dr. MacCabe, Local Government Board Inspector, recently inspected this workhouse, and reports in reference to its sanitary condition that the increased numbers resident during the past six months have led to overcrowding in some of the departments, and as a result there has been an unusually large number of cases of fever and other infectious diseases transferred to Cork-street and Hardwicke Fever Hospitals. By a recent arrangement observation wards have been provided in the workhouse, a provision which will tend to prevent the spread of infectious diseases in future; and the guardians are considering the necessity of providing shed accommodation within the Union, but outside the city, for the reception and treatment of infectious diseases.

An order has been issued by the Local Government Board which will remove a serious grievance which has been felt by district medical officers in various parts of the metropolis. This order provides that, subject to the approval of the Local Government Board, it shall no longer be requisite that a metropolitan district medical officer shall be called upon in every case to reside within his district. There are parts of London where it has been found impracticable for a medical officer to secure a suitable residence within his district, and other parts where a substantial injustice has been done to the medical officer by a strict adherence to the rule of residence, without advantage to the working of the district. It will now be practicable to remove those difficulties on sufficient cause being shown to the Local Government Board.

Dr. Archer Farr, the medical officer of health for Lambeth, having been called upon by the Sewers and Sanitary Committee of his Sanitary Authority to prepare a special report on the number of beds Lambeth should contract for, under the Poor-law Amendment Act of 1879, in the Metropolitan Asylums Board Hospitals, has reported that he is unable to express an opinion on the subject until he can obtain some clearer knowledge of the mode in which pauper and non-pauper cases will be discriminated by the Asylums Board.

Mr. Clare Sewell Read has written a letter to *The Times*, expressing his regret that he was unable to take a part in the deputation of the British Medical Association to the President of the Local Government Board on the 26th, to protest against the Vaccination Acts Amendment Bill. He had been influential in causing a similar provision to that now proposed being thrown out of the Amending Bill of 1871, and had he known of the proposed deputation he should have volunteered to be a member of it.

Metropolitans who are desirous to study the pig- nuisance may do so, it appears, very conveniently in Arthur-street, Chelsea, which rejoices (or rejoiced a few days ago) in 115 of these interesting and useful inmates. A proposition submitted to the Vestry for prohibiting the keeping of pigs in thickly populated neighbourhoods, and doing away with this particular relic of rural Chelsea, was, notwithstanding that it was supported by piteous complaints of "dreadful smells," rejected by a majority of one.

It is proposed by the Metropolitan Asylum Board to make additions to their Deptford Hospital, so that cases of fever as well as of small-pox may be received and treated there.

Mr. Hawkins, the Inspector of Anatomy for the Home Office, attended a meeting of the Sanitary Authority for St. Pancras on the 24th inst. with reference to the alleged nuisance from the private dissecting-room in the disused burial-ground of St. George-the-Martyr. Mr. Hawkins expressed the opinion that the complaints were not justified either by the situation or the management of the building, and the Sanitary Authority passed a resolution in accordance with this view of the question.

The Medical Officer of Health for Greenock (Dr. James Wallace) reports a mortality for the five weeks ending 3rd July equal to an annual rate of 16·2 per 1000 population, compared with 18·7, 17·7, and 21·2 for the period of the years 1877, 1878, and 1879 respectively. The returns of infectious sickness included six cases of typhus (and probably four other cases), all, with one exception, connected with cases noted in previous reports.

A batch of twenty persons were recently summoned before the Bedford Borough Bench of magistrates for refusing to have their children vaccinated. In each instance the defence of "conscientious scruples" was urged, and apparently accepted, for the Bench inflicted, it is reported, a nominal fine of sixpence in every case, remitting the costs altogether! This lenient course in cases of this class has been followed by the Bedford Bench, it is asserted, for some time back.

Clapham, it appears, objects to having an apparatus for the disinfection of clothes within its precincts. Things that require disinfection, according to the local magnates, should be destroyed by fire. Besides, an apparatus would cost £100. Of course, destruction of infected things is not to be effected without cost, as proprietors have to be indemnified. Obviously the way out of this economical difficulty is neither to destroy nor disinfect!

The Metropolitan Asylum Board, at the request of its solicitors, drew a cheque the other day for £1989 16s. 10d., the taxed costs of the plaintiffs at the last hearing of the Hampstead Hospital case. It was stated that it was extremely doubtful whether the pending further proceedings in this case would be heard before the adjournment of Parliament.

The Local Government Board have approved of the scheme proposed by the Cavan Town Commissioners for supplying this town with water. The Commissioners have selected Beaghy Lake as the source of supply, and from it a sufficient amount can be obtained for all necessary purposes.

VITAL STATISTICS.

HEALTH OF LARGE ENGLISH TOWNS.

THE fatality of infantile summer diarrhoea showed a further increase last week, but the total mortality was again considerably below the average. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5217 births and 2955 deaths were registered last week. The births exceeded by 32, whereas the deaths were no less than 320 below, the average weekly numbers during 1879. The deaths showed, however, a further increase of 63 upon the exceptionally low numbers returned in recent weeks. The annual death-rate per 1000, which had been but 18·9, 19·2, and 20·1 in the three preceding weeks, further rose last week to 20·6. During the past three weeks of the current quarter the death-rate in these twenty towns has averaged 20·0 per 1000, against 23·0 and 17·5 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 13·8 in Nottingham, 13·9 in Plymouth, 14·0 in Newcastle-upon-Tyne, and 16·0 in Hull. The rates in the other towns ranged upwards to 22·7 in Salford, 22·8 in Sunderland, 23·7 in Leicester, 24·7 in Wolverhampton, and 26·0 in Liverpool. The high death-rates in Salford and Leicester were mainly due to excessive zymotic fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 567 in the six preceding weeks, further rose to 636 last week; these included 337 from diarrhoea, 108 from scarlet fever, 74 from whooping-cough, and 63 from

measles. The annual death-rate from these seven diseases averaged 4·4 per 1000 in the twenty towns; whereas it was but 0·7 in Plymouth, it ranged upwards to 7·3 and 7·6 in Brighton and Leicester. Scarlet fever showed the largest proportional fatality in Sheffield, Norwich, Salford, and Bradford; and measles in Leicester. Two deaths were referred to diphtheria in Leicester. Small-pox again caused but three deaths in London, and not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 191 and 200 at the end of the two preceding weeks, were 198 on Saturday last; 22 new cases of small-pox were admitted to these hospitals during the week, against 17 and 13 in the two previous weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

The deaths referred to diarrhoea in the twenty towns, which in the five preceding weeks had steadily increased from 51 to 258, further rose last week to 337, and included 202 which occurred in London. The annual death-rate from diarrhoea averaged 2·3 per 1000 in the twenty towns; it was equal to 2·8 in London, while it did not exceed 1·8 in the nineteen provincial towns. The highest death-rates from diarrhoea among these towns were 4·9 in Brighton, 3·6 in Leicester, and 3·1 in Salford.

The deaths referred to diseases of the respiratory organs in London, which had been 171 and 176 in the two preceding weeks, fell to 161 last week, and were 2 below the corrected average in the corresponding week of the last ten years. The annual death-rate from diseases of this class did not exceed 2·3 per 1000 in London; it was equal to 4·9 in Liverpool, and 3·4 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate, which had been 20·9, 20·4, and 18·6, in the three preceding weeks, rose again to 20·6 last week, and was identical with the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 11·6 and 13·6 in Aberdeen and Perth, to 22·9 and 29·7 in Glasgow and Paisley. The fatal cases of the seven principal zymotic diseases in the eight towns were 107, against 97 and 109 in the two previous weeks; they included 39 from diarrhoea, 21 from whooping-cough, 16 from scarlet fever, 13 from measles, 12 from diphtheria, and 6 from fever. The annual death-rate from these seven diseases averaged 4·3 per 1000 in the eight towns, against 4·4 in the large English towns. No zymotic death was registered in Perth; whereas the rate from these seven diseases ranged upwards to 4·4 in Leith, and 6·0 in Glasgow. The fatal cases of diarrhoea in these eight towns further rose last week to 39, which were, however, not equal to a higher rate than 1·6 per 1000; whereas the death-rate from this disease averaged 2·3 in the large English towns. In Glasgow 27 of the 39 deaths from diarrhoea were recorded, showing a rate of 2·4 per 1000. Twelve of the 13 fatal cases of measles, and 10 of the 21 deaths from whooping-cough, also occurred in Glasgow. The 12 deaths referred to diphtheria included 5 in Glasgow, and 5 in Edinburgh; and of the 6 deaths referred to fever, 5 occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight Scotch towns were 69 last week, against 90 and 58 in the two preceding weeks; the annual death-rate from these diseases was equal to 2·9 per 1000, against 2·0 in London. The causes of no less than 23 per cent. of the deaths registered in these Scotch towns last week were uncertified; while in the English towns the proportion did not exceed 2·5 per cent.

THE HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had declined in the six preceding weeks from 42·5 to 30·3, further fell last week to 30·2, a lower rate than has prevailed in that city since the end of October last. The average death-rate during the past three weeks has, however, been 30·6 per 1000, against 20·2 in London and 18·3 in Edinburgh. The 182 deaths in Dublin last week included 42, or 23 per cent., which were referred to the seven principal zymotic diseases, against 53, 47, and 45 in the three preceding weeks; 9 resulted from small-pox, 11 from scarlet fever, 7 from fever (including typhus and typhoid), 7 from whooping-cough, 4 from diarrhoea, 3 from measles, and 1 from diphtheria. The annual death-rate from these seven diseases was

equal to 7.0 per 1000 in Dublin, against 5.0 in London, and 3.4 in Edinburgh. The 9 fatal cases of small-pox showed a further slight decline from recent weekly numbers; whereas those of scarlet fever and fever were somewhat more numerous. The deaths from measles were fewer than they have been in any week since the middle of May. The fatality of diarrhoea was considerably smaller in Dublin last week than in most of the large English towns.

OFFICIAL MORTALITY STATISTICS IN QUEENSLAND.

A supplement to the *Queensland Government Gazette*, which has recently come to hand, contains a report on the vital statistics of Brisbane and its suburbs for the month of March issued by the Registrar-General. The population of the city and suburbs is estimated at 32,012, and 43 deaths are reported as having occurred during the month. Instead, however, of giving, as is now done in nearly all parts of the civilised world, the equivalent annual rate of mortality per 1000 persons living, the Registrar-General of Queensland gives the percentage of the deaths in the month to the total population, which is valueless for comparative purposes. It is stated that the deaths in the month in Brisbane were equal to 0.13 per cent. of the estimated population. This gives no clue to the annual rate of mortality, which we calculate to have been not higher than 15.8 per 1000 of the population. We will venture to suggest to Mr. Jordan, the Registrar-General, that, as his figures are published in the official *Gazette* for general information, their utility would be much enhanced by the publication of the equivalent annual rate of mortality. It is noticeable that the death-rate in the suburban portion of Brisbane appears to be considerably higher than it is within the municipality.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

WOOLSORTER'S DISEASE AT BRADFORD.

Another death from the woolsorter's disease has occurred in the neighbourhood of Bradford, and has been the subject of a coroner's inquest. The deceased, a man forty-nine years of age, named James Greenwood, was engaged in sorting "inferior mohair" at the works of Messrs. John Foster and Son, at Queensbury. From the evidence it appeared that the wool is washed before sorting. The deceased complained of pain in the limbs on the 17th inst., but continued at work until the 22nd, when he was obliged to desist. He was restless and sleepless during the night; and when seen by a medical man next morning was in a state of collapse, his other symptoms simulating bronchitis. He died at noon, twenty-four hours after leaving work. A post-mortem, made by Dr. Brittan together with Mr. Spear, the Medical Inspector of the Local Government Board, showed that the cause of death was anthrax.

As we mentioned two or three weeks ago, some cattle died of splenic fever at a farm at Harden, upon which the washings of Van mohair were distributed. An interval of time has elapsed since these cases, this interval coinciding with the cessation of work at the Harden Mills. We now learn that another animal, this time a sheep, pastured in the same fields, has died of the same disease, and there is some evidence that this occurred coincidentally with a resumption of the washing at the mill. The carcase was examined by Dr. Roberts, Medical Officer of Health for Keighley, and microscopic examination showed conclusively that the disease was splenic fever.

The interest excited by the inquiry into the disease does not seem at all to have abated. We learn from the *Bradford Observer* that the manufacturers are taking measures for concerted action in the washing of all noxious wool. At a recent meeting they passed a series of resolutions, based in some degree upon the recommendations of the coroner's jury in a former case, which we have already given (*vide* THE LANCET, June 19th, p. 977).

The following is the text of the resolutions of the employers, which have been submitted to the Sanitary Committee of the Corporation:—

1st. That all Van mohair, camels' hair, and Persian wool, and all damaged wools, are noxious, and must be dealt with before sorting.

2nd. That all average mohair, Cape hair, Peleton and alpaca, are to be sorted as usual (damaged excepted).

3rd. That, in dealing with noxious wools, before a bale is opened it shall be steeped in hot or cold water for a period of not less than ten hours. In case the covering does not freely admit the water it shall be opened so as to do so.

4th. That, after the bale has been in the water the necessary time, the hair or wool shall be placed in a sud of hot water, and washed, then passed through rollers, partly dried, and sorted whilst still damp, as early as possible after washing. The heat of the water to be 100 to 120 degrees.

5th. That sorting-rooms shall be well ventilated, the floors swept daily, the walls and ceilings swept once in three months and thoroughly cleansed, and the walls lime-washed with lime mixed with carbolic acid once in twelve months.

6th. That no bale-wool shall be stored in the sorting-room, and no wool, hair, or other material shall be kept in the said room so as to interfere with the proper ventilation thereof.

7th. That no meals shall be taken in the sorting-room, or food kept there. Also, that proper provision be made for the sorters to wash in or near the sorting-room.

It is suggested that these regulations should be submitted to the Local Government Board for their sanction, and that, if necessary, steps should be taken to obtain a legal enactment. But it is clear that, pending the issue of the inquiry now being carried on by the Medical Department of the Board, no such regulations can be adopted; and it may very probably be found that the suggested regulations are insufficient to meet the requirements of the case.

THE WELBECK POISONING CASE.

As the case of poisoning at Welbeck now stands, it seems probable that the cause of the numerous instances of sickness following upon the consumption of beef and ham sandwiches at the sale, is to be assigned to a peculiar state of change in the meat, short of putridity, after its exposure to sewer air. It would appear that in the intervals of the sale the meat was stored in a room in which was the untrapped inlet of a drain which communicated directly with the system of sewers of the mansion, and there is evidence to show that it lay there in an atmosphere highly charged with sewer air. Dr. Edward Seaton, the medical officer of health for Nottingham, gave evidence at the adjourned inquest on the fatal case of William Wilkinson very much to the point. He stated that nine cases of individuals suffering from symptoms similar to those the deceased had suffered from, and all of whom had been at the Welbeck sale, had come under his observation at Nottingham. His opinion, after what he heard, was that it was extremely probable that the state of the meat being slightly putrid from poisonous air from drains, was such as would cause the symptoms. He had met with like cases arising from the consumption of meat which had undergone some change. He had in his recollection a group of six persons, in two families, in which the symptoms were somewhat similar, though not in all respects, but which were unquestionably due to the eating of meat short of putridity. Dr. Ballard, of the Medical Department of the Local Government Board, was present at the inquest, and gave assistance to the Coroner in questioning the witness on the medical and hygienic aspects of the inquiry. The jury returned the following verdict in the particular case under their consideration: "That the cause of death was English cholera induced by eating unwholesome meat at Welbeck, but how it became contaminated there is no positive evidence."

POONA POWDRETTE.

The *Gazette of India* for the 19th ult. contains an important memorandum by the Superintending Engineer for Irrigation on the manufacture of pouquette at Poona, and a report on the same subject by Mr. Narso Ramchandra, the Secretary of the Poona Municipal Committee. It would appear that by a mixture of night-soil and of ashes, resulting from the burning of the street refuse, house-sweepings, and dust-bin refuse, a pouquette is formed of the greatest value in garden cultivation, and which is in increasing demand. The night-soil, spread between thin layers of the ashes described, and first sifted, is dried in the open air, under the sun in the fine season, under sheds in the rainy season. When the requi-

site degree of dryness is reached, the night-soil and ashes are then thoroughly mixed together, and more sifted ashes added. The material is then ready for distribution. At first the native gardeners hesitated to take the poudrette; now the manufacture does not meet the demand, and it is frequent for payment to be made from four to six months in advance, in order to secure a supply. The nuisance experienced in the process of manufacture appears to be comparatively slight, stink not being experienced at a distance of more than fifty yards to windward, and of 150 yards to leeward of the drying tanks. The financial results are regarded, even in the present state of the experiment, as highly satisfactory, the profit from the sale of the poudrette during the first year having reduced the scavenging expenses of the municipality 5000 rupees. The sale of the poudrette, which in 1874-5 realised 766 rupees, in the nine months April to December, 1879, realised 7438 rupees.

THE "FEVER" IN IRELAND.

Dr. Nixon's further reports on the state of fever in the Swinford Union, County Mayo, confirms the impression derived from his previous reports that maculated typhus is widely disseminated there, even in the remoter districts. The incidental descriptions he gives us of the conditions under which he found the disease make the reader almost despair of the sanitary future of the localities to which the descriptions refer. Any way his sanitary prescriptions seem almost a mockery in face of severe dearth, and what to the English reader has the aspect of hopeless impoverishment and degradation. Writing of the small village of Faheens, three miles from Swinford, he says, "The condition of the people here is, however, extremely wretched. In most of the cabins cattle and pigs are kept in the room that is occupied. The sewage matter is partly carried off by an open drain which runs through the centre of the floor, whilst stagnant pools, containing all sorts of offensive matter, lie in front of the cabins. In this village there is no sewerage of any kind, and no road for a car within more than a mile's march. The food of the people here consists almost exclusively of Indian meal without milk." Of a village in another part of the Swinford district he writes:—"Nothing could exceed the complete absence of sanitary arrangements in this village. There was fully eight inches of manure in one cabin in the room where seven persons lived, and the woman of the house explained that she could not clear it out, as then she would have no manure." Again, writing of a house in the village of Ballintadder, he says, "Five members of the family had been ill for some weeks, and at the time of my visit three were still confined to bed; all appeared to have suffered from typhoid fever. The cabin in which these persons lived was extremely offensive, and on entering it the smell from the excessive amount of organic matter in the air was almost overpowering. In the small single-roomed cabin in which the three patients—the mother and two children—lived, I counted at the time of my visit three cows, a number of chickens, three cats, and a large dog."

Mr. W. E. Forster, referring in the House of Commons to certain suggestions of Dr. Sigerson and Dr. Kenny relating to districts in Mayo, observed that the Local Government Board (Ireland) were doing their utmost in the matter, but it should be remembered that the sanitary condition of the cabins in those districts had been very bad for generations, and it was a matter which could not be remedied in a day.

SICKNESS AT SIMLA.

The Indian papers report a severe and troublesome epidemic of diarrhoea at Simla, which had attacked Europeans of all classes during the month of June. In addition to the usual "hill diarrhoea," from which new arrivals in the Himalayan Sanitaria are extremely prone to suffer, this present sickness was remarkable for its persistence, its constant relapses, accompanied by languor and great debility; vomiting of a bilious character was present more or less in the early stage, with, in some cases, a degree of lassitude and prostration that almost amounted to collapse. No case had terminated fatally. The weather during May and June had been unusually hot and muggy, and the epidemic was regarded by the medical officers on duty at Simla as probably due to atmospheric causes. The setting in of the monsoon at the end of June would, it was hoped, clear the atmosphere and wash away the disturbing elements.

DAIRY FARMING IN SWITZERLAND.

The *Journal de St. Pétersbourg*, quoting from the Russian journal *Béreg*, states that the milk industry of Finland is not only the largest in the Russian Empire, but in Europe generally. Under the fostering care of the Government this industry has of late years undergone great development. There are now seventeen schools in Finland for the training of persons in the management of milk. The course of study occupies two years. During the first year the student is taught the physiology of the cow, the discrimination and treatment of the diseases to which it is subject, the mode of rearing calves, and the general management and treatment of kine. In the second year the course of treatment embraces a knowledge of the constituents of milk, the influence of temperature upon them, and the use of the thermometer in the management of the fluid, the different methods of manipulating milk and preparing butter and cheese, and book-keeping. In order to encourage the cultivation of this industry the students leaving the schools receive subsidies of from 500 to 1000 Finland marks, to help in the organisation of farms. The results obtained by this mode of procedure are said to have been most brilliant.

YELLOW FEVER.

The Royal Mail Company's cargo-steamer *Derwent* has arrived at Havre infected with yellow fever. In the course of the homeward voyage eighteen cases of the disease occurred on board, and the chief officer and two of the crew died of it. The cases which recovered are all reported convalescent, and the ship will be released from quarantine if after three days' detention no other cases of sickness manifest themselves. The importation of yellow fever into New York Harbour is also reported by a steamship, the *Colon*, from Aspinwall, which arrived there on the 15th ult. A case occurred on board the day after the ship left Aspinwall, and two cases were removed from the ship into the quarantine hospital on Swinburne Island, New York Harbour.

DIPHTHERIA IN RUSSIA.

A considerable diminution in the prevalence and mortality of diphtheria is reported in the Government of Poltava. This is attributed to the measures of disinfection which have been adopted; but, it is added, both the peasant and the clergy object to these measures. There has been an outbreak of the disease in the districts of Tchéboksary and Kazan; but by the prompt despatch of a medical staff of nurses to the localities, destroying infected material by fire (the proprietors being indemnified), forbidding the exposure of the corpses in churches, and covering them when placed in the grave with quicklime, the disease has been arrested in its progress.

FAMINE IN INDIA.

The first part of the Report of the Indian Famine Commission has been issued; it relates to famine relief, and is a most comprehensive document. After some preliminary sections, it discusses the rainfall of India, the history of past famines (freely illustrated with maps), the general considerations affecting the administration of State relief, and then enters upon the consideration at large of practical recommendations.

NOXIOUS VAPOURS.

Among the measures destined to be abandoned in Parliament during the present session is unfortunately that of Noxious Vapours. Lord Enfield, however, speaking for the President of the Local Government Board, has stated from his place in the House that he earnestly hopes early next session to introduce a measure to carry out the recommendation of the Royal Commission.

This week at the Dublin Police-court two men were fined forty shillings each for having obstructed a sanitary officer who wished to remove a child suffering from scarlatina to hospital, there being several healthy people occupying the same room as the sick child.

The hospital for infectious diseases at Cuningharhills, Aberdeen, says the *Weekly Free Press*, was opened on the 19th and closed on the 26th of June, two patients having been successfully treated for small-pox in the interval.

The erection of a hospital for infectious diseases at Uxbridge is decided upon.

THE SERVICES.

WIMBLEDON MEETING.

The camp at Wimbledon was, as in previous years, under the medical charge of Surgeon-Major Elkington of the Grenadier Guards, and Acting-Surgeon Pocklington, 11th Surrey Rifle Volunteers. The meeting passed off without any accident, and, with the exception of considerable prevalence of slight diarrhoea at first, the health of the camp is reported to have been good.

ADMIRALTY.—Staff-Surgeon R. L. Bett has been promoted to the rank of Fleet Surgeon, with seniority of Feb. 15th, 1880. Fleet Surgeon R. R. Beaumont, 1869, to Haulbowline Hospital. Surgeon M. M. R. Mackenzie, 1879, has been appointed to the *Boadicea*, vice Dr. Gordon, promoted to the rank of Deputy Inspector-General. Surgeon Alexander Blood Trousdell, M.D., has been promoted to the rank of Staff-Surgeon in Her Majesty's Fleet, with seniority of 24th inst.

ARMY MEDICAL DEPARTMENT.—Surgeon-General William Munro, C.B., has been appointed to succeed Surgeon-General Huntley Gordon as Principal Medical Officer at Gibraltar. Dr. Munro has for several years conducted the duties of Head of the Medical Branch of the War Office, Whitehall Yard. Surgeon-Major A. Guthrie has been appointed Principal Medical Officer of the Reserve Division Afghan Field Force, vice Deputy Surgeon-General Hanbury, transferred to the Khyber Division.

Correspondence.

"Audi alteram partem."

"SALICIN AND THE SALICYLATES IN RHEUMATIC FEVER."

To the Editor of THE LANCET.

SIR,—I have been much interested by the excellent annotation in THE LANCET of June 5th, headed "Salicin and the Salicylates in Rheumatic Fever." It falls to my lot to see but few cases of rheumatic fever. My experience, of course, has been much greater as to cases of chronic and articular rheumatism, sent to Buxton for relief from the use of its mineral water, and as to cases of gout. In these cases I have very frequently made use of both salicin and the salicylates, and at times with much, and at times with signal benefit. I am of opinion that they are sometimes of at least as much value in chronic as they can be in acute cases, exercising probably in some degree a restorative action, and aiding the system in the elimination of morbid material. To some extent the same value attaches to the use of quinine, arsenic, or the other well known and trusted antiperiodic tonics, sustaining or ministering to the general tone, and thus tiding over the struggle between the system and the disease, and perhaps helping to secure or promote the elimination of the hampering and irritating morbid products. What, however, I would seek to suggest is, that the treatment of acute rheumatism may not consist only in the lessening of the inflammatory and febrile struggle, which may be done by many other means, such as alkalies, salines, diaphoretics, aperients, or by colchicum, &c., or in the use of such remedies as will lower the febrile condition, as evidenced by the reduction of abnormal temperature, such as quinine, salicin, or even alcohol in carefully regulated doses, but may demand, as the primary consideration, the avoidance of any means by which elimination can be interfered with, and the use of any means by which it may be promoted, either by restorative or emulgent treatment. It need not be said that the relief of gout pains, and of the violent paroxysms of acute gout, may be commonly secured by the use of colchicum; but that the relief may have to be paid for by the supervention of an indolent form of the disease, diminished elimination of gouty material, increase of chalky deposit, and greater general malaise and debility. Every means of relief to gouty conditions, no matter whether acute or chronic, must

embrace the conservation of the general strength as much as may be, and a constant use of all the means that will help to secure the fullest elimination of the morbid products. I cannot but feel that all this may have a considerable bearing upon the moot question of the use, or relative use, of salicin or the salicylates in acute rheumatism. There can be no doubt that a morbid product is the necessary outcome of the disease. Febrifuge treatment on the one hand, or restorative treatment on the other, will not necessarily aid the elimination of this product. In cases where the febrifuge effect of salicin is indicated, or its possibly restorative value is needed, it might be aided as to eliminating power by judicious salines, diaphoretics, diuretics, or aperients, and the utmost advantage be thus obtained from its exhibition. In cases where neither its power of lowering temperature nor its restorative value is needed it might be wisely withheld, and a more simple regard be given to action upon some of the emulgent organs or tissues. There can be no doubt that rest in bed, with what diaphoresis can be secured by bed-clothes, warm-water compresses, and tepid or cool drinks, with or without the aid of alkaline or diaphoretic medicines, will often prove to be the best treatment for any of the acute forms of disease primarily requiring relief by elimination of morbid material; and that in either acute or chronic cases of this character the best treatment may consist in the free application of cotton-wool to the parts affected, and a careful regulation of the ingesta, avoiding if possible the use of stimulants altogether.

I think the profession is much indebted to Dr. Greenhow for his careful report upon these comparatively new remedies; but I should be sorry to think that they may not retain a position of much value in the treatment of certain cases and conditions of both rheumatism and gout; while I feel that we are not likely to have specifics for any disease that would be suitable to all its instances, that there are no two cases alike, that one case demands one primary consideration, another requires some other help. The febrile heat, or the weakness, or the congestive engorgement, or defective elimination, may be the principal indication for treatment; but any treatment that does not include the elimination of morbid products in such a disease as rheumatism must be imperfect, and be attended with consequences that must be disappointing.

I am, Sir, most faithfully yours,

WM. H. ROBERTSON, M.D., F.R.C.P.,

Consulting Physician to the Devonshire Hospital and Buxton Bath Charity.

Buxton.

COPPER TEST CAPSULES FOR SUGAR.

To the Editor of THE LANCET.

SIR,—The thanks of the profession, I am sure, are due to Dr. Pavy for the suggestion which has rendered the application of the copper test for sugar more convenient and its constituents more stable.

The substitution of the glass stopper for the sealing-wax cork will, no doubt, in great measure prevent the damp from acting on his "test pellet"—the only objection that has been hitherto brought against it. At the same time it must not be overlooked, that it may happen that the stopper will not be always replaced immediately. Moreover, a glass-stoppered bottle is not a very convenient article to carry about with one.

I have, therefore, ventured to suggest an improvement on Dr. Pavy's "pellet," by enclosing a small quantity of Fehling's solution in hermetically-sealed glass capsules, each containing about one cubic centimetre of the test solution. Air being thus excluded, the solution will keep almost an indefinite time. The size of the capsules being small, two or three can be conveniently carried wrapped in a bit of cotton-wool either in the ordinary pocket-case or waistcoat-pocket, without fear of breaking. They are made by Mr. Martindale, of 10, New Cavendish-street.

The test capsules are an improvement on the fine tubes that have been used for the same purpose for some years, because from their size and shape they are less likely to break, and are therefore more portable.

I am, Sir, yours truly,

CHARLES HENRY RALFE.

11, Anne Street, W., July, 1880.

FOREIGN BODIES SWALLOWED BY CHILDREN.

To the Editor of THE LANCET.

SIR,—We are often consulted by mothers as to what is best to do in cases where children have swallowed foreign bodies; and such things as coins, buttons, marbles, &c., are common enough, and are generally passed without causing any disturbance whatever. The following case appears to me unique, from the peculiarity of the body swallowed.

On the afternoon of April 10th last I was consulted by a lady as to what was advisable to do with her child, a girl aged about three years, who had swallowed the tongue of a hand-bell with the chain attached. The child was playing on the floor with the bell, and was seen by an elder sister suddenly to struggle in a suffocative paroxysm. With praiseworthy promptitude, she held the child head downwards and thumped her well on the back. In a few seconds the child got relief, the obstruction passing down; and on the mother hastening to the room she appeared all right.

Knowing that before the tongue could be separated from the bell some of the links must be open, I considered it a very dangerous thing, as the open link might catch in any part of the intestine; I accordingly ordered the child to be fed for the next few days on porridge, hard-boiled eggs, cheese and bread, with very little fluid, in the hope that the chain would become embedded in thick stool, and so protect the alimentary canal from injury. On the following day a small motion was passed, and about noon of the second day (forty-eight hours after swallowing it) the tongue, with links attached, was passed *alone*, followed in a few minutes by a copious motion. The annexed sketch is the exact size, and will give some idea of the thing. The tongue is of brass, and weighs rather more than two drachms.

This case seems interesting from the fact that although the child was fed on constipating food, the foreign body was passed *alone*, and that, such being the case, there was not a single bad symptom then or since.

Yours faithfully,

WM. CAIRNS WICKS, M.B. Edin.,
Physician to the Hospital for Sick Children,
Newcastle-on-Tyne.

PAGET'S DISEASE OF THE NIPPLE.

To the Editor of THE LANCET.

SIR,—As I believe it to be important that the fatal effects of the disease of the nipple, to which Sir James Paget has directed attention, should be widely recognised, I venture to send you a few notes regarding a case which has been reported to me by my friend, Dr. Johnston, of Shanghai. Dr. Johnston, following the examples of previous observers, writes of the disease as an eczema, a term that on practical as well as on theoretical grounds, I think it very desirable should cease to be applied to this affection.

Mrs. E— was sent from Peking to Shanghai to be under Dr. Johnston's care on account of a tumour which had formed in the breast, and told him that the nipple had been affected with superficial disease for more than a year before she was aware of the existence of a tumour. Dr. Johnston operated, but the disease recurred within six months, and the patient died.

Before going to China she had been under the care of Mr. Lockhart, of Blackheath, to whose kindness I am indebted for the following note. Writing to me on February 3rd of this year, Mr. Lockhart remarks:—"When Mrs. E— was in London, about three years and a half ago, I saw her several times. She had eczema round the nipple, extending from the nipple as the centre one inch and a half all round. This proved wholly impracticable so far as curing it went. I tried all that I could suggest—lead, zinc, arsenic internally, barley water, gruel, and much else, but the eczema remained. There was no tumour in the mamma of any kind, but I feared, as the eruption was so inveterate, that there might be something malignant about it, although I hoped on to the last

of her stay in England that this would pass away. The next I heard of her was from Dr. Dudgeon, of Peking, that she had cancer of the mamma."

In order that sufficient data may be obtained for the construction of trustworthy rules for the differential diagnosis between what, with Mr. Erichsen, I prefer to call Paget's disease and simple eczema of the nipple, there are some points regarding which in any given case information is especially desirable, and I risk the suggestion that in recording other cases reporters would do well to state whether the affection began on one small localised point of the nipple and remained so localised for any length of time, and how long it was before the whole surface of the nipple became affected; whether the affection of the skin of the areola was from the first sharply demarcated towards the healthy skin, and whether, as the disease spread, the sharp line of demarcation was never lost; whether the border of the diseased skin was elevated; whether it felt hard when compressed from the margin between the fingers; the nature of the discharge; the presence or absence of pain and itching; and whether before there were any signs of disease there had been a "weeping" from the nipple. By comparing the symptoms in a sufficient number of cases with those present in the obstinate eczemas of which the nipple is occasionally the seat, the early diagnosis of Paget's disease, on which the safety of the patient so much depends, will become easier than it is at present.

I am, Sir, yours, &c.,

Queen Anne-street, W.

GEORGE THIN, M.D.

THE DISPUTE AT GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—The suggestion of Dr. Harding of Whittlesea is, I am afraid, not capable of being put into practice, since a committee of "old Guyites" would have no *locus standi* with the Governors.

As far as that is of any use to them the staff have all the sympathy which we all old Guyites can give them, but that will avail them little. I would, however, make another suggestion: whether the committee now sitting, or the Board of Governors, should not take into consideration the desirability that the internal management of the hospital should be left entirely to the staff—the treasurer having nothing to do with that. The principle is the one you have consistently advocated in the case of military hospitals, where you have repeatedly pointed out that laymen (old colonels) are ridiculously out of place in the management of hospitals, such as Haslar Hospital.

This unfortunate affair, which must have grieved every Guy's man, is the outcome of certain notions floating in the brain of a well-meaning, possibly somewhat imperious, gentleman, who certainly must have a very considerable amount of self-confidence to pit his experience against a whole staff.

I have been dresser, obstetric resident house-surgeon, and house-physician at Guy's ten years ago, and consequently was at that time well acquainted with the whole management of the wards. And, on the whole, I believe the nursing and the comfort of the wards were excellent.

I think there was too much laxity as to stimulants. Many a sister has told me that she wished she did not have the care of them. But this and other details are things with which the staff could deal much better than the treasurer. Let the committee now sitting remember that "Behind the horseman rides black care." Behind them is public opinion, which will not suffer Guy's to come to harm. Let them be intent not upon adjudicating the dispute, but upon finding a remedy.

I am, Sir, your obedient servant,

T. D. L. TEMPLE, M.D. Lond., F.R.C.S. Eng.,

Old House-Surgeon and House-Physician.

St. James's-road, Hatcham, New Cross, July 12th, 1880.

To the Editor of THE LANCET.

SIR,—In a letter with the above heading which appears in to-day's LANCET, Mr. Stanley Gale, when referring to my paper on Hospital Nursing in the July number of *Fraser's Magazine*, does me an unintentional injustice. He makes it appear that I am, in some sense, an advocate for the training or employment of a number of unqualified female

practitioners, or, as he calls them, "female quacks," who are in reality imperfectly educated women, who have received some elementary instruction, when probationer nurses, in strapping, dressing, bandaging, &c. It is surely not necessary for me to deny this soft impeachment? Any one who has read my paper will bear me out in saying that it can be made to yield no such argument from first to last.

I lay down as the first principle of successful nursing that everyone who is responsible for the conduct of this department of hospital work must be guided by common sense views. I show that there are hospitals and hospitals—viz., those with medical schools and those without. At the former class there will be a large body of students who will require for their instruction all the raw material which the wards can provide. At such hospitals no dressing or other minor medical or surgical work will be required from sisters or nurses. On the other hand, at the country and other non-clinical hospitals, all this is changed. Here a nurse is of little use unless she can undertake much of the dressing, the taking of temperatures, the testing of various matters, and a fair share of the minor medical work, which elsewhere devolves upon the student. It happens, therefore, that a nurse trained wholly at a clinical hospital, where she has few opportunities of learning dressing, &c., is of little use in an institution where there are no students and few skilled assistants. This very week I have met with a King's College nurse who had never seen a breast removed, and who was quite at sea during the operation and of little use. Here lies the kernel of the nursing dispute at Guy's. Miss Burt, the matron, thinks she can adopt one particular system to every hospital; she might just as well try to fly.

I am, Sir, your obedient servant,

HENRY C. BURDETT.

Seamen's Hospital, Greenwich, S.E., July 24th, 1880.

ENTERIC FEVER IN INDIA.

To the Editor of THE LANCET.

SIR,—As I am much interested in the subject which has lately been occupying the attention of the Epidemiological Society I cannot refrain from offering a few remarks on the subject of enteric fever as observed in India. That *enteric* fever properly so-called does exist in India, and that as a definite disease always recognisable after death in fatal cases by the pathological changes proper to it, no one will, I apprehend, attempt to deny. The question at issue seems to me to be briefly this, Is enteric fever in India due to the insanitary conditions similar to those to which it is attributed in temperate climates, or is it merely a form of the "malarial fevers"? I have always held that enteric fever in India is thoroughly distinguishable from all other forms of fever, which, more or less, simulate it at various stages, with one proviso, that the patient is seen early in the disease, and that the temperature is taken then, and regularly watched throughout the disease. Without this precaution it will be found almost impossible after the fifth day to say whether a given case is one of "enteric" (pythogenic) fever or "remittent" (malarial), and only too often nothing but the result of the "post-mortem" examination will enable us to diagnose the case with accuracy. If, however, we can take the temperature early in the disease, and in most cases if "remittent" we can do this the very first day, the course of the temperature will afford us an almost certain means of diagnosing "enteric" from malarial fever. For suppose we find the temperature 104° or 105° F on the first day, we can predict with absolute certainty that the disease will not prove to be enteric; whereas if we have a case as to the nature of which we are in doubt—e.g., given a patient in the second week with all the symptoms of remittent fever, which differs very slightly in its clinical aspect from enteric fever in the same stage—we have only to consider the temperatures of the first day or two to find ourselves able to state with a very considerable degree of certainty whether it is a case of "enteric" or "malarial" fever, whether, that is to say, we shall in the event of a fatal issue find the post-mortem appearances pathognomonic of enteric fever or not.

Taking it then for granted that enteric differs in *toto* from malarial fevers in its mode of access, I think there is no valid reason for saying that "enteric" fever is due to the

same causes which induce "malarial" fevers. I admit that it is very hard to obtain positive evidence as to the "pythogenic" nature of enteric fever in India; but when we consider the following points, we may, I think, regard it fairly well proved that enteric fever in India depends upon local insanitary conditions quite as much as elsewhere.

1. Natives suffer from the disease to a considerable extent, far more so than Europeans, at least more than those who adopt the precautionary measures of filtration of drinking-water after boiling, and avoid all possible sources of faecal contamination.

2. There is no station in India, however carefully its sanitary condition may be attended to, where the conditions for faecal contamination of water easily accessible for drinking, though not intended for that purpose, do not exist in profusion.

3. These very conditions are those which affect the native community, who are notoriously careless about their drinking and cooking water.

Seeing, then, that insanitary conditions sufficient in themselves to cause enteric fever always exist in India—that these insanitary conditions affect the native portion of the community almost exclusively, and that this native community suffers from enteric fever in a far larger proportion than the European residents who are not so affected—it is hard to resist the natural conclusion that enteric fever in India is due to those same insanitary conditions which, when they exist in temperate climates, are recognised by the highest authorities as efficient causes of the disease in question.

I am, dear Sir, faithfully yours,

GEORGE RANKING, M.D. Cantab.,

Surgeon 6th Bengal Cavalry.

Phoenix-park, Dublin, July 15th, 1880.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—It is satisfactory to hear from Mr. Clay that Chian turpentine is still producing satisfactory results "in cancer of various organs." Others are not so successful as himself in their trials; and as he still holds to his former opinion, one is almost obliged to conclude that they have not been using "the true remedy." We have to depend on the honesty of those who supply our drugs, and it is difficult to believe that they take advantage of us when we ask for a supply of the genuine article. Not only would such treatment be unfair to their customers, but it would be *cruel and unkind* to their customers' patients. What are we to conclude, however, when, after trial, we find the disease still progressing? Is the remedy only a myth, or have we been deceived in the nature of the drug by the chemist? Mr. Clay still writes of success, and consequently it is difficult to doubt his word. Under these circumstances would it not be a kindness for Mr. Clay to mention publicly where he obtains his Chian turpentine? His repeated assertion gives one a hope of doing good; but when, after trial, no improvement succeeds, despair takes its place, and we feel that we have cruelly raised "false hopes" in the minds of our patients.

I enclose my card, and am, Sir, yours faithfully,

COUNTRY PRACTITIONER.

THE NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Notwithstanding the flagrant disabilities under which the naval medical service at present labours, the authorities still continue to advertise for candidates to fill its attenuated ranks. You, on the other hand, render good service not only to those of the profession, who presumably are aimed at—the wavering ones—but to those at present in the service, by bringing to public notice the injustice under which they suffer in comparison with the more liberal treatment accorded to the army. As you truly remark, "we find a difficulty in believing that such a difference of action should arise under the same circumstance affecting two bodies of our profession serving the same Government in a military or combatant capacity," and it is to be hoped that forthcoming candidates for the August examinations will well weigh your advice, and "appreciate at the commence-

ment of their career what are the possible harvests to be reaped at its end." You might with justice have added, *to contrast the difference existing during their whole career.* One could understand the action of the authorities in quietly ignoring the well-known grievances of the department if it was in contemplation to allow it, like the navigating branch, to die a natural death; but it seems this is not their wish. Judging from the persistency of their advertisements, it is, as of old, a question to be determined by the profession. Are we to be ignored? I have no doubt the answer will be given by our brethren in no uncertain tone. Three men came forward to compete for eighty vacancies last examination; let there be *none* for the next.

I am, Sir, yours, &c.,

OMEGA.

PARIS.

(From our own Correspondent.)

FOR some time the atmosphere of Paris has been anything but agreeable. Towards the evening an unpleasant smell—or, rather, a more unpleasant smell than usual—has been noticeable; so much so, indeed, that it has at last become offensive even to the republican nostrils of the Municipal Council. This odour has been supposed by some to emanate from the sewers, whilst others have attributed it to putrefaction in the numerous *kiosques* which adorn (or disfigure?) the boulevards. It would appear, however, that the effluvium originates outside the fortifications, in the twenty-seven *depotoirs*, or night-soil depôts, which at some distance surround the capital, and perhaps also in the sewage-boats, which are anchored in the Seine, near the Pont des Invalides. It depends in a great measure upon the absence of the disinfectants which should be used by the contractors who empty the cesspools, but who appear, from the statement of one of the municipal councillors, to have been abetted by the police in their neglect.

A list of the prizes awarded annually by the Academy of Medicine was given in THE LANCET last year, but I would again call the attention of those members of the profession who are engaged in scientific research to the fact of their existence, and to the possibility of obtaining them. As usual, a large number were not awarded this year, either because no essays were sent in, or because those which did compete were not of sufficient merit.

For 1881 the subjects are as follows:—Prize of the Academy, 1000 francs: to determine the clinical value of antiseptic methods in surgical practice. Portal Prize, 1500 francs: on the state of the uterus and its dependences in puerperal fever. Civrieux Prize, 1500 francs: on the epileptiform symptoms of hysteria. Capuron Prize, 2000 francs: the indications and contra-indications for the use of mineral waters; sea-bathing, and hydropathy in pregnancy. Godard Prize, 1500 francs: for the best work upon external pathology (surgery). Daudet Prize: upon epithelioma of the lips and its treatment. There is also a prize of 6000 francs, which was founded by Dr. Barbier, to be given to the person who shall find a curative treatment for diseases which are generally supposed to be incurable, such as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera. When the prize is not awarded in its entirety, a part of it may be given as an encouragement. Your readers may be reminded that in addition to the money value of the prize itself, successful competitors acquire the title of "Laureate" of the Academy of Medicine.

Obituary.

S. B. GWYNN, F.R.C.S.

SAMUEL BETTON GWYNN, who died very suddenly on July 11th, at the age of fifty-seven, was a son of Edward Gwynn, and grandson of Edward Gwynn (senior), both former surgeons of Wem. He commenced his medical education by being apprenticed to his father, and afterwards studied at Edinburgh, and at King's College Hospital, London. He obtained his M.R.C.S. Eng. and L.S.A. diplomas in 1844, and the Fellowship of the Royal College of Surgeons in 1853.

He began general practice with his father at Wem, where he was a well-known and successful practitioner for nearly forty years. Mr. Gwynn's quiet, unobtrusive, and kindly disposition gained for him the general respect and affection of all classes, for he was not only a skilful surgeon, but also a real friend to poor and rich alike. He was for many years medical officer of the Wem Union and several Friendly Societies, and for twenty-seven years surgeon to the North Shropshire Yeomanry Cavalry. He had been failing in health for three years, but continued in active practice to the very last day of his life, his sudden death being due to heart disease consequent upon emphysema of the lungs. He leaves a widow and nine children; but his loss is deeply deplored by many besides his own family, as was testified by the hundreds who voluntarily followed his body to the grave.

ALBERT J. WALSH, F.R.C.S.I.

THIS gentleman died on Saturday last at Whitechurch, near Dublin, at an advanced age. When the Adelaide Hospital in that city was established, in 1858, Mr. Walsh was appointed one of the visiting surgeons, a post he occupied until the last few years, when failing health obliged him to resign, and he was elected consulting-surgeon to the hospital. The deceased, who until recently had a considerable amount of practice, and was a very skilful operator, was an ex-President and Member of Council of the Royal College of Surgeons in Ireland, and was formerly attached as surgeon to the Maison de Santé.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Friday, petitions against the Vaccination Acts Amendment Bill were presented from the Edinburgh Branch of the British Medical Association, the Faculty of Physic in London, Whitechapel Board of Works, and Newton Abbot Union.—Mr. Puleston gave notice that he would move to add Dr. Farquharson to the Select Committee on the Contagious Diseases Act, in the place of Sir Harcourt Johnstone.

On Monday, Sir Trevor Lawrence asked the Parliamentary Secretary to the Local Government Board whether the attention of his department had been drawn to an allegation that a species of black mail is exacted in connexion with the certification of pauper lunatics in the Kensington Union. Mr. Hibbert replied that the officers of the Union denied that any such charge was levied. The report might have arisen owing to the great number of cases that had been sent to two particular medical officers, the reason being that they resided in the immediate neighbourhood of the infirmary.—Replying to the same hon. member, Sir W. Harcourt stated that the Government would consider during the recess the subject of the embarrassed financial position of the United College of the University of St. Andrews, with a view to seeing before next session whether any steps could be taken to relieve the College from its pecuniary difficulties.—Lord F. Cavendish stated to Mr. M. Brooks that it would not be practicable to employ women clerks in the preparation of the census returns.—Mr. Watkin Williams asked the Secretary to the Local Government Board whether any regulations exist defining the duties of relieving officers and medical officers of Poor-law unions in relation to orders for the supply of medical necessities to the sick poor, and whether it is competent to relieving officers to disregard or overrule at their discretion the orders of the medical officers; and, if so, whether the Local Government Board will consider the propriety of altering the regulations in question. Mr. Hibbert replied that, whilst the relieving officers had a certain discretion in such matters, they were cautioned by the Local Government Board to be very guarded in the exercise of that discretion.—On the motion of Mr. Meldon, a return was ordered of the names of all medical officers of work-houses and dispensaries in Ireland, who, since the passing of the Medical Officers Superannuation Act, 32 & 33 Vic. c. 50, have resigned their offices and applied to those officers of guardians for superannuation allowances under that Act, with the causes for such resignation; the ages and length of service as Poor-law Medical Officers of each person at date

of resignation; the result of such application to the guardians; and the reason, if any, given by the said guardians for refusing the application.

On Tuesday, further petitions against the Vaccination Acts Amendment Bill were presented from Manchester, the British Medical Association (two), Warrington, Royal College of Surgeons (England), Hackney, Saltley, and Macclesfield.—Mr. Meldon asked the Chief Secretary to the Lord Lieutenant of Ireland if it is the case that the medical officer of the Crossgar dispensary district in the union of Banbridge, having after forty years' service applied for superannuation on the ground of broken-down health, a meeting of the guardians has been summoned to consider such application, and to pass a resolution "to record on the minutes their approval of the manner in which the medical officer has filled such office for a period of forty years, but that the guardians cannot add to the rates by granting any retiring allowance." And, if the Government will promote or support a measure to make the superannuation of Poor-law medical officers, in proper cases, compulsory on boards of guardians?—Mr. Forster pointed out that the resolution had not yet been passed, and therefore the question was somewhat premature. He would defer any answer for the present.—Mr. Macdonald asked the Secretary of State for the Home Department if his attention had been called to an inquest held on Wednesday, the 14th instant, at the White Horse Tavern, St. Matthew's, touching the death of a youth named William Ball. If it were correct that he died from the effects of poison inhaled when following his employment as a copper-bronze printer. Whether there were any provisions in the Factory and Workshops Act to prevent youths from being employed in such an atmosphere as will cause the death of those that may be employed where such work is carried on. And, if there were no provisions now in existence, would he cause the suggestions made by Dr. Tidy to be carried out, which were as follows: "the free use of milk or other albuminous fluid by the workpeople employed; the wearing whilst engaged at the work a cotton-wool respirator of sufficient size to cover efficiently both mouth and nostrils; that the bronzing should be carried out in a separate compartment or room, and not in the general workshop, in order as far as practicable to limit the evil; that a dress of glazed calico or like material tied round the neck and waist should be worn by those engaged at the work, and that this dress should be removed before leaving the compartment where the process is conducted; that strict cleanliness should be enforced."—Mr. A. Peel, the Under Secretary, replied that it was true that William Ball died from the effects of poison inhaled whilst following his employment as a copper-bronze printer, but there were no provisions in the Factory and Workshops Act preventing the employment of youths in copper-bronze printing, and the Secretary of State had no power to extend the provisions of the Act. The Act did provide for ventilation, but ventilation in a case of this kind was practically inoperative, the bronze dust being of such a heavy character. The Secretary of State could only call attention of employers in the trade to the danger of the present conditions of working, as shown in this question, and direct attention also to the suggestions of Dr. Tidy, and to the usefulness of a "dusting-off" machine, which had been found very beneficial in getting rid of the dust. Mr. Macdonald, therefore, gave notice that on Monday he would ask the Home Secretary whether, considering that Wm. Ball was poisoned while in the performance of his duties, he would not direct the public prosecutor to take up the case, and have it tried, as a warning to employers of labour who keep their workshops in such a condition that the health and the lives of their workers were destroyed. He considered this a most disgraceful case, and—(cries of "Oh!" and "Order," amidst which the hon. gentleman resumed his seat).—Mr. Puleston gave notice that on Thursday he would ask the Secretary of State for the Home Department whether his attention has been called to the present condition of Guy's Hospital and to the statements made by the senior physician in a letter to *The Times* of Saturday last, and to the report of the inquest since held in the hospital; and whether, as the hospital is subject to the control of Parliament, he will take steps to remedy a state of affairs which is calculated to impair the usefulness of the institution.

On Wednesday, in reply to Mr. Hicks, Mr. Gladstone said no restriction would be placed on the use of any materials in brewing, except such as were absolutely mischievous. The substance called saccharum, or condensed maize wort, would

be charged by the excise officers as sugar. At the close of the sitting the Lunacy Law Amendment Bill was withdrawn.

On Thursday, the chief interest, of course, centred upon the news from Afghanistan. From the lists read by the Marquis of Hartington it appeared that amongst the officers of General Burrows's force who reached Candahar in safety were Surgeon-Major Harvey, Horse Artillery; Surgeon Burroughs, 3rd Scinde Horse; J. Eaton, 16th Native Infantry; and A. Dane, 1st Native Infantry. The answer given by the Home Secretary to Mr. Puleston's question, with regard to the recent inquest at Guy's Hospital, was as follows:—I have no power to interfere, but the unfortunate circumstance to which this question relates is the subject of judicial investigation, so that it will be thoroughly investigated in a court of law. I have confidence that the Governors of Guy's Hospital will consider the matter very fully.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 22nd inst. :—

Briscoe, J. Frederick, West Hackney.
Clark, William, Hampstead.
Corbould, H. Francis, Thornton-heath.
Elliot, E. A. Savage, Kingsbridge, Devon.
Ford, L. Frederick, Highgate.
Hendley, John Lupton, Dover.
Hockin, George Treverno, Beckingham.
Hoets, Alton Kingsley, L.S.A., Adelaide-road.
Hills, A. Phillips, Battersea.
James, Charles Alfred, Plymouth.
Jones, A. C. Brett, Lavender-hill.
Morris, E. F. Griffith, L.S.A., Hereford.
Newnham, W. H. Christopher, Wolverhampton.
Lloyd, Rickard William, Wood-green.
Stansby, Charles John, L.S.A., Hoxton-street.
Steeves, George Walter, Liverpool.
Taylor, Henry Herbert, Lewisham.
Wakefield, Horace, Alwyne-place.

The following gentlemen were admitted Members on the 23rd inst. :—

Acland, Theodore Dyke, L.R.C.P. Lond., Oxford.
Batterham, John Williams, Haverstock-hill.
Coronado, Daniel Enrique, M.D. Paris, Colombia.
Lane, Alexander, Bishop's-castle, Salop.
Milnes, George Hutchinson, Turnditch, Derbyshire.
Phipps, E. V. Ayre, Husbands Bosworth.
Pizey, G. F. Price, Clevedon, Somerset.
Risk, E. J. Erskine, Plymouth.
Street, Alfred Francis, M.B. Cantab., Whittlebury, Towcester.
Tucker, Joseph, L.S.A., Chulmleigh.
Westcott, Sinclair, Plymouth.
Wilson, George John, Brixton.

The following gentlemen were admitted Members on the 26th inst. :—

Barnes, George Frederick, Weymouth.
Chitty, Alfred Goldney, Dedham, near Colchester.
Duncan, Duncan, Buckingham-palace-road.
Fenton, H. A. Hill, Cumberland-street.
Grayling, Arthur, Forest-hill.
Lerew, Frederick William, Maida-vale.
Quicke, William Henry, L.S.A., Brixton-road.
Richardson, Richard Tippetts, L.S.A., Hackney.
Silk, J. F. William, L.S.A., Gravesend.
Terry, Henry George, L.S.A., Mells, Frome, Somerset.
Weston, George Edward, L.R.C.P. Edin., Bognor, Sussex.
Wood, Edward Archer, Marlborough.

The following gentlemen were admitted Members on the 27th inst. :—

Clarke, Ernest, Hampstead.
Clarke, William Jenner, L.S.A., St. Augustine-road.
Doyle, Robert Walter, Seymour-street.
Dobraschian, Gabriel Sukias, Constantinople.
Field, James William, Chesham, Bucks.
Howard, Eaton Clark, Devonshire-road.
Jackson, Mark, L.S.A., Great Torrington, Devon.
Jay, M. H. Hindmarsh, Adelaide.
Jessop, W. H. Hylton, B.A. Cantab., Vernon-street.
Nichols, Frederick Peter, B.A. Cantab., Bury-street.
Taylor, Thomas Percy, L.S.A., Bocking, Essex.
Volckman, Ronald, L.S.A., Upper Norwood.
Woodhouse, Tom Percy, L.S.A., Pontefract.

The following gentlemen were admitted Members on the 28th inst. :—

Battiss, William Sullivan, L.S.A., Southsea.
Bradshaw, O. G. Dix, Bath.
Burton, F. H. Merceron, Avenue-road.
Carpenter, Arthur Bristowe, Croydon.
Carr, Alfred Alexander, New Barnet.

Collins, William Job, Albert-terrace.
 Hayward, John Davey, L.S.A., Liverpool.
 Macnamara, Hugh Winckworth, Uxbridge.
 Neumann, Joseph, M.D. Berlin, Bedford-square.
 Shepard, Ernest William, Euston-road.
 State, Alfred, Ockenden-road.
 Thompson, Charles Emilius, L.S.A., Delamere-street.
 Welch, George, Leamington.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on July 22nd :—

Barnes, Henry John, Thornhill-terrace.
 Brown, James Grierson, Liverpool.
 Dresser, Arthur Kinnaird, St. Oswald road, West Brompton.
 Hughes, Thomas William, Royal Infirmary, Glasgow.

The following gentlemen also on the same day passed their Primary Professional Examination :—

Wm. Oliver Tyndall Annesley, Greville Ewing Seon, and Alfred Geo. Clarke Pocock, St. Thomas's Hospital; Howard Bennett Fletcher, Sheffield School of Medicine; George Trevor Harley Thomas, St. George's Hospital; John Alex. Shaw, University College; John William Blampied, St. Bartholomew's Hospital; Michael Anthony de Quadros, Grant Medical College, Bombay.

COLLEGE OF PHYSICIANS IN IRELAND.—At the July examinations the following obtained the licences in Medicine and Midwifery of the College :—

MEDICINE.—James Henry Beattie, Robert Ettingsall Beattie, George Harry Broadbent, Fanny Jane Butler, Alexander Cosgrave, Patrick Richard Dennehy, Augustus Newton Dickenson, Geo. Philip Elliott, William Henry Fitzmaurice, Hubert Flanagan, William Gibbon, William Frederic Gilbert, Henry Wilson Stocker Hall, John Hugh Harricks, James Kernan, John M'Cullagh, William Joseph Magee, Anthony H. Morgan, Patrick O'Donaghue, James Joseph O'Dwyer, William Renner, Samuel Sharpe, John Whittake Tate, Henry Clark Wilson.

MIDWIFERY.—James H. Beattie, Robt. E. Beattie, Geo. H. Broadbent, Fanny Jane Butler, Alexander Cosgrave, Hubert Flanagan, William Fredk. Gilbert, Henry Wilson Stocker Hall, John Hugh Harricks, James Kernan, John M'Cullagh, George Henry Manning, James Joseph O'Dwyer, William Renner, Samuel Sharpe.

The undermentioned were admitted Members of the College on the 9th inst., the names being arranged in order of seniority :—

Henry Gray Croly, Charles H. Robinson, Richard Warren Pendleton, Charles Trussell Bridgford, Robert R. King Elmes.

DR. REID, jun., of Ellon, has been elected President of the Buchan Medical Society for the ensuing year.

The Visitors for the Isle of Ely and the County and Borough of Cambridge have determined to appoint an assistant medical officer for the county lunatic asylum.

ST. STEPHEN'S GREEN, Dublin, which has been beautified and improved by Lord Ardilann at a cost of £20,000, was opened to the public on last Tuesday, the 27th instant.

The salary of **Mr. James Allen, L.R.C.P. Edin.**, M.R.C.S. Eng., Medical Officer of Health to the Bollington Urban Sanitary Authority, has been increased from £10 to £20 a year.

DR. DIXON has been presented by the nurses of the Newcastle-on-Tyne Infirmary with an elegant silver-mounted decanter, as a mark of esteem, on his resignation of the senior house-surgeoncy of the institution.

H.R.H. THE PRINCESS CHRISTIAN has consented to open the Herts Convalescent Home on the 21st October. The new institution is intended to accommodate 44 patients. About £1500 is still required to meet the entire cost of the building.

The vicar and churchwardens of Temple parish, Bristol, have consented to the opening, as a garden, of a burial-ground long unused for interment and closed against the public. This is a step which should be taken in other parishes similarly circumstanced.

MR. R. NUNN, surgeon to H.M. Prison at Warwick, destroyed himself on Sunday by taking a dose of prussic acid. Deceased, who was very much esteemed in the borough, is stated to have been overworked lately, and finally his mind gave way.

TRINITY COLLEGE, DUBLIN.—The Council have recently adopted a resolution, in addition to that passed in May last, by which certificates in ophthalmic surgery will not be accepted from any hospital that does not maintain permanently fourteen beds for ophthalmic cases only.

MR. T. T. LINART, late Medical Officer to the First District of the Bedminster Union, has been awarded a superannuation allowance of £80 a year. Mr. John Vance, late medical officer for the Plaistow district of the West Ham Union, has received a similar allowance of £30 a year.

A **BAZAAR** on a grand scale was held last week on the grounds of Easthill House, Colchester, the residence of Mrs. Round, in behalf of the funds of the Essex and Colchester Hospital. It is expected that the proceeds, when the accounts are made up, will prove to be very large.

MR. GEORGE CROOM ROBERTSON, M.A., Professor of Logic and Philosophy of Mind, University College, London, has been appointed one of the External Examiners of the New Victoria University, as has also been Mr. James Bryce, D.C.L., M.P., Regius Professor of Civil Law, Oxford.

At the annual meeting of the supporters of the General East-end Tradesmen's Association in aid of the London Hospital, it was announced that the amount of subscriptions in behalf of the Association showed an increase on that usually received. A total number of thirty-two life governors had been made out of the funds of the society.

ADELAIDE HOSPITAL, DUBLIN.—The following prizes have been awarded at the termination of the session 1879-80 :—Senior Surgical prize : Messrs. Cuppage and Polden (equal). Junior Surgical prize : J. H. Scott. Senior Medical prize : Messrs. Hull and Polden (equal). Junior Medical prize : F. W. Elsner. Obstetrical prize : T. C. Moore.

CITY OF DUBLIN HOSPITAL.—The directors of this hospital, having incurred a debt of £1951 for improvements, &c., during the last few years, made an appeal a few months ago for funds to defray the amount. This has been liberally responded to, and £1347 has already been received, leaving a balance due of some £600, which it is expected will shortly be obtained.

It is to be regretted that the Woolton Convalescent Institution is, like many medical charities at the present time, suffering from want of funds. At the annual meeting of the friends of the Home, held on the 17th inst., the report read showed a balance of expenditure over receipts of £260. The chairman, however, mentioned a gratifying fact—viz., that many of the substantial subscriptions to the funds of the institution were from societies connected with the artisan class.

ACCIDENTS IN MINES.—The Home Office has just issued the annual reports for 1879, presented to the Home Secretary by the Inspector of Mines. The summaries show that during the year 1879 the aggregate number of persons employed in and about the whole of the mines in the United Kingdom of Great Britain and Ireland amounted to 523,870 persons. Of these 476,810 were employed under the Coal Mines Regulation Act, and 47,060 under the Metalliferous Mines Regulation Act. The total number of fatal accidents was 843, and the total number of deaths occasioned thereby 1037, showing a diminution compared with the totals for 1878 of 39 in the number of fatal accidents, and of 453 in the number of lives lost.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

CARRINGTON, R. C., M.D., M.R.C.P., has been appointed Visiting-Physician to the Dreadnought Seamen's Hospital at Greenwich, vice Dr. C. H. Raffe, F.R.C.P., resigned.

CORBY, H., M.D., M.Ch., has been appointed Assistant-Surgeon to the North Infirmary, Cork.

CORKE, C. A., L.F.P.S.G., L.S.A.I., has been appointed Medical Officer for the Baschurch District of the Ellesmere Union.

CULLING, J. C., M.R.C.S.E., has been appointed Resident Medical Officer to Charing-cross Hospital.

DAVIES, D. W., M.D., C.M., has been appointed Medical Officer for the Llanharan District of the Bridgend and Cowbridge Union.

FRASER, J., M.D., L.R.C.P.L., L.R.C.S.Ed., has been appointed Physician to the Toronto General Hospital.

GEIKIE, W. B., M.D., F.R.C.S.Ed., L.R.C.P.L., has been appointed Consulting Physician to the Toronto General Hospital.

GRIMWOOD, H. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District and the Workhouse of the Pontefract Union, vice Simpson, resigned.

HININGS, J. W., L.R.C.P.E.D., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator of the Knightwight District of the Martley Union, vice Mr. David Holmes, resigned.

HUGHES, T. J., M.D., M.R.C.S.E., has been appointed Medical Officer for the West Woolwich District of the Woolwich Union.

JACKSON, G., F.R.C.S.E., has been appointed Honorary Surgeon to the Plymouth Public Dispensary, vice W. B. Stephens, M.R.C.S.E., resigned.

JONES, T., M.B., F.R.C.S.E., has been appointed one of the Honorary Surgeons to the Manchester Royal Infirmary, vice Bradley, deceased.

MCCLURE, H., M.D., M.Ch., has been appointed Medical Officer for the First District of the Romford Union.

MAKINS, G. H., F.R.C.S.E., has been appointed Dispensary Surgeon to the Sailors' Dispensary, Well-street, London Docks, which will be opened in connexion with the Dreadnought Seamen's Hospital, Greenwich, in September next.

MOORE, H. C., M.B., has been appointed House-Surgeon to the Lancaster Infirmary and Dispensary, vice Collis, L.K.Q.C.P.I., resigned.

MURISON, J. F., M.B., C.M., has been appointed Medical Officer for the Parish of Cumbernauld, Dumbartonshire.

NICHOLSON, A., L.R.C.G.Ed., L.F.P.S.G., has been appointed Medical Officer for the First District of the Hunslet Union.

O'SULLIVAN, S., M.D., M.Ch., L.R.C.S.Ed., has been appointed Visiting Surgeon to the North Infirmary, Cork.

PHILLIPS, J. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Cowbridge District of the Bridgend and Cowbridge Union.

RYERSON, G. S., M.D., L.R.C.S.E., has been appointed Surgeon to the Mercer Eye and Ear Infirmary, Toronto General Hospital.

SHEAF, C. A. E., F.R.C.S., M.R.C.P., has been appointed Medical Officer to the Board of Trade for the Port of Barrow-in-Furness.

SHEARD, C., M.R.C.S.E., has been appointed Pathologist to the Toronto General Hospital.

SLOMAN, S. G., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the South District of the Farnham Union.

SOUTHAM, F. A., M.A., M.B., F.R.C.S.E., has been appointed Honorary Assistant-Surgeon at the Manchester Infirmary, vice T. Jones, M.B., F.R.C.S.E., appointed Hon. Surgeon.

STEAD, Mr. J. E., has been appointed Public Analyst for the Borough of Middlesbrough. £10 10s. per annum and fees.

WARE, J. W., M.R.C.S.E., L.R.C.P.L., has been appointed House-Surgeon to the North Devon Infirmary, vice Kay, resigned.

WATSON, G. S. M.B., C.M., has been appointed Medical Officer for the Thaxted District of the Dunmow Union.

WORRALL, Mr. R., has been appointed Medical Officer for the Workhouse of the West Derby Union, vice W. B. L. Langley, deceased.

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On the 24th inst., at the Rectory, Hargrave, Northamptonshire, the wife of Surgeon-Major T. Young Baker, A.M.D., of a daughter.

DARLEY-HARTLEY.—On the 26th ult., at East London, Cape Colony, the wife of W. Darley-Hartley, M.R.C.S., L.R.C.P., of a daughter.

MANDERS.—On the 22nd inst., at Agincourt House, Yorktown, the wife of Horace Manders, F.R.C.S., of a son.

PHILLIPS.—On the 13th inst., at Woodville, New Ferry-park, Cheshire, the wife of Ed. J. M. Phillips, M.R.C.S.E., L.D.S., of a son.

RENSHAW.—On the 21st inst., at School-road, Sale, Cheshire, the wife of Israel J. E. Renshaw, of a daughter.

ROOSE.—On the 22nd inst., at Regency-square, Brighton, the wife of Robson Roose, M.D., F.R.C.P., of a son.

SMITH.—On the 25th inst., at Caistor, Lincolnshire, the wife of Tom Smith, M.R.C.S.E., L.R.C.P., of a daughter.

THORNTON.—On the 24th inst., at 83, Park-street, Grosvenor-square, W., the wife of J. Knowles Thornton, M.B., C.M., of a daughter.

MARRIAGES.

BIDEN—JONES.—On the 28th inst., at St. Cybi's, Holyhead, by the Rev. Morris Jones, B.A., William Price Biden, M.R.C.S.E., of St. Mary's-road, Peckham, and Hyères, France, to Ellen Elizabeth Jones, of Ffynnon y Gorlas, Holyhead.

COUPLAND—POTTER.—On the 27th inst., at St. Andrew's, Bath, by the Rev. Prebendary Anderson, A.M., Sidney Coupland, M.D., F.R.C.P., of Weymouth-street, Portland-place, third son of the late W. N. Coupland, of Streatham, to Bessie, youngest daughter of the late Thomas Potter, of Great Bedwin.

GROVES—AUGERAUD.—On the 22nd inst., at St. Mary Abbots, Kensington, by the Rev. T. J. Williams, Rector of Waddesdon (cousin of the bride), assisted by the Hon. and Rev. E. Carr Glynn, Vicar of the Parish, and the Rev. H. Huleatt, late Chaplain to the Forces (First Class), and Vicar of St. John's, Bethnal-green, James Mary Julia Nelly, daughter of the late William J. P. Augeraud, Esq., and step-daughter to H. L. Harper, Esq., of 19, Addison-road, Kensington.

HOBSON—ARMITAGE.—On the 27th inst., at St. Martin's, Scarborough, by the Rev. James Hope, M.A., of Holy Trinity, Halifax, assisted by the Rev. C. G. Foster, M.A., Lewis John Hobson, M.B. Lond., B.S., F.R.C.S., of Scarborough, to Frances Vernon, youngest daughter of the late George Armitage, Esq., J.P. & D.L., of Milnbridge House, Huddersfield, and Nunthorpe, York.

KAY—THOMPSON.—On the 22nd inst., at Newport Parish Church, Barnstaple, North Devon, William Kay, M.R.C.S.E., L.S.A.L., of Barnstaple, to Mary Ellen (Lillie), elder daughter of the late Isaac Thompson, J.P., of Workington, Cumberland.

DEATHS.

CARTER.—On the 25th inst., at 69, Wimpole-street, after lingering illness, Helen Ann Beauchamp, the beloved wife of Robert Brudenell Carter, aged 48. Friends are requested to receive this intimation.

GREIG.—On the 18th inst., at Sunnyside, Fyvie, A. F. Greig, M.R.C.S.E., aged 65.

PEARSE.—On the 24th inst., at Penzance, John Pearse, Surgeon, late of Tavistock and Wisbech, aged 65.

PHELAN.—On the 23rd inst., at his residence, Grove-road, Rock Ferry, Cheshire, William Bernard Phelan, L.R.C.P.E., L.R.C.S.E., &c.

TREVAN.—On the 18th inst., at Padstow, Henry Trevan, F.R.C.S.E., Fleet-Surgeon, R.N. (retired).

WALSH.—On the 24th inst., at Whitechurch, near Dublin, Albert J. Walsh, F.R.C.S.I.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS ETC. RECEIVED.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

"CRUELTY TO WOMEN."

We are about to reissue our list of houses of business at which seats are, or will shortly be, provided for women serving behind counters and in show-rooms. Firms desiring to be included in the same will please to communicate.

DRINK FOR RAILWAY TRAVELLERS.

At some of the stations on the principal railways outside London, what is called "iced water" is provided and handed round—or perhaps we ought to say hawked about—in wire baskets. The idea is a good one, but could not the companies be generous enough to give their customers a few glasses of cold water? There need be no great trouble or expense in the matter. The water need not be actually iced; it is not now—or if it has been, that must have been some time ago. The jugs from which the dirty little boys playfully fill up the dregs left in dirty glasses by those consumers who are not so thirsty as to drink every drop, do not stand in a refrigerator, but on a table or bench somewhere on the platform, and sometimes of course in the sun. The only drawback we foresee to the plan proposed—namely, that the companies should take the business in their own hands—is, that the lessees of refreshment-stalls might ask to have their rents reduced. There need not be any haste in this respect. By continuing the practice of serving out water a little longer as it is now conducted, the public will be sufficiently disgusted to fall back on the old-fashioned seltzer with a drop of "something" in it. The "ow much?" ejaculated by each dirty little boy, as he sees one of his colleagues sell a glass of "iced water," draws attention to the matter, and the manner in which the glass is seen to be filled up from a tepid solution of dead flies is not appetising.

Dr. Irving.—We gave our correspondent an opportunity of defending himself against the statements made with regard to the administration of the General Hospital, Calcutta; but we cannot accept him as the self-constituted champion of Dr. D. B. Smith in our columns, more especially as he bases the defence on his impressions, and comments upon the report of a Committee appointed so far back as 1870; nor do we think it necessary to obtain, as he suggests, "from the Government of Bengal a copy of Dr. Smith's unpublished utter."

Mr. R. T. Tickling.—The treatment alluded to is practised, and in some cases with success. We would recommend consultation with a good general surgeon, who could probably suggest more suitable treatment.

July, 1880.—The charge for the stamp for the Membership or Fellowship of the College ad eundem is 20s.

Dr. A. H. Bennett.—The paper will appear in an early number.

ACUTE RHEUMATISM TREATED BY HOT WASHING-SODA BATHS.

In the *Australian Medical Journal* for April, two cases of acute rheumatism treated by hot washing-soda baths are reported by Mr. Bingham Crowther, L.R.C.P., as occurring under the care of Dr. E. L. Crowther. In this treatment the patients are taken in a blanket by the four corners, and lowered down in a recumbent position into the bath. Half a pound of common washing-soda is added to the water as hot as can be comfortably borne, the patient remaining in from ten to fifteen minutes, then lifted into a dry warm blanket, and replaced in bed. According to the reporter, profuse diaphoretic action follows along with diuresis, to the immediate relief of the sufferer, pains rapidly depart, and sleep follows the use of the remedy. In one severe case convalescence was effected in eleven days. The other case was treated without permanent benefit with salicylate of soda and various sedatives and salines. On the 25th of December, 1879, "the patient becoming immovably fixed in bed by the affection of new joints, and all remedies proving useless, the washing-soda bath was tried as a last chance. After remaining in ten minutes he was removed. His complexion soon changed from a muddy to a natural colour, and the pains left the joints." On the 27th there remained only a little aching in the body and slight pain in the left wrist. Complete recovery having been established on the 8th January, the baths were discontinued.

Mr. James T. R. Davison.—We do not know.

DR. TANNER'S FAST.

To the Editor of THE LANCET.

SIR,—It may interest some of your readers to know that some five years ago I attended a lady over sixty years of age who suddenly refused food in every shape and form. I never found out the reason why she did so, but I fancy it was owing to some family trouble. Be this as it may, she lived for exactly seven weeks, and died on the forty-ninth or fiftieth day, during the whole of which time she took nothing but cold water—at first freely, but gradually in smaller quantities—with one exception of a dessertspoonful of brandy in water, which was never repeated. All offers on my part to force food with the stomach-pump or enema were steadily refused by patient and friends. They were people in a good position, and there was no reason for deception of any kind; in fact, most of the friends are still alive, and if any member of the profession would like to sift this case I shall be happy to give him every facility for so doing. I may mention that the lady in question was always remarkably quiet in manners and very taciturn, seldom, when quite well, speaking unless in reply to some question. She was also very stout, and some few years earlier I had operated upon her for strangulated umbilical hernia, from which she recovered without a bad symptom; and at the time of her death, although her legs and arms had become very thin, her body retained much of its previous stoutness.

I am, Sir, yours, &c.,

July 27th, 1880.

M.D.

To the Editor of THE LANCET.

SIR,—As a considerable amount of attention is just now called to the possibility of protracting life for a lengthened period without food, perhaps the following case may be worth notice:—

R. G.—, a man of spare build, very recently deceased, had been under my care for the last three years. For some time past his occupation was that of gardener, until constantly recurring pains and weakness obliged him to relinquish all work. Without going into particulars I may state that his disease was cancer of the stomach. For forty-one days before his death he took no food of any kind, either liquid or solid, merely moistening his lips from time to time with water. For four months previously the amount of nourishment in any shape of which he partook, might be contained in an ordinary breakfast cup. His wife assures me—and I have no reason to doubt the truth of her statements—that during the previous twelve months he would only take a morsel of food once in every two or three days, as the agony he suffered after receiving anything into his stomach made him so dread its renewal that he would remain without food till forced by sinking and weakness to take some further nourishment.

There was great emaciation for a considerable time before death, but he was perfectly sensible to within twelve hours of his decease, could speak in a whisper, and knew those around him.

I am, Sir, yours, &c.,

Meadowside, Putney, July 26th, 1880. G. STANLEY MURRAY, M.D.

Only a Provincial Fellow should write to the Honorary Secretary, Mr. B. T. Lowne, F.R.C.S. The following list of provincial Fellows who have been Chairmen of the Fellows' festival will, no doubt, be found correct:—In 1847, Mr. J. S. Soden, of Bath; 1849, Mr. J. Hodgson, of Birmingham; 1851, Mr. J. H. James, of Exeter; 1853, Mr. Wilson, of Manchester; 1855, Mr. Norman, of Bath; 1857, Mr. Smith, of Leeds; 1859, Mr. T. Paget, of Leicester; 1861, Mr. J. Wickham, of Winchester; 1863, Mr. T. Turner, of Manchester; 1865, Mr. P. C. De la Garde, of Exeter; 1867, Mr. T. Green, of Bristol; 1869, Mr. T. Nunneley, of Leeds; 1871, Mr. H. D. Carden, of Worcester; 1873, Professor Humphry, of Cambridge; 1875, Surgeon T. Longmore, of Netley, Southampton, as representing the Army; and 1877, Mr. E. L. Hussey, of Oxford.

W.—We do not reply to questions unaccompanied by name and address.

LUNACY IN IRELAND.

It appears from the recently issued report of Irish Lunatic Asylums for the past year that there has been an increase of 234 in the number of insane over that of the preceding year; but the Commissioners, bearing in mind the fact that from the unbroken severity of the last winter and the destitute condition of whole counties throughout Ireland for many months, most of the imbecile and idiotic were forced to seek shelter in workhouses, infer that the total 12,819 not only supplies a very fair estimate of the actual amount of insanity in Ireland in its various forms, but affords evidence that the disease cannot be regarded as really on the increase. During the past year, 2392 were admitted into district asylums, of which number 1955 were cases of a first attack and 438 of relapses, the comparatively large number of the latter indicating a marked difference between the liability of a recurrence of disease in mental and physical affections. Of the 10,800 under treatment in district asylums, 1004 were sent out recovered, being at the rate of 42 on admissions, and not quite 10 on the whole number under treatment; 245 were improved, and 105 unimproved. The mortality amounted to 940, being equal to a death-rate of $8\frac{1}{2}$ on the entire number in asylums, the increase being due to the harshness of the weather and the prevalence of bronchial diseases. Two of the deaths were accidental and one suicidal; and when we learn that upwards of 1300 lunatics were committed as dangerous or violent, the result is very gratifying. Of 8490 resident in district asylums on the 1st of last January, 1861 were married, 467 widowers or widows, 5816 single, and in 346 instances the social condition was unknown. This discrepancy between the number of married and single inmates is remarkable, and is totally at variance with what is elsewhere recognised.

Mr. M. Bull.—The communication has been received, and will be inserted as early as our arrangements will permit.

THE INDIAN MEDICAL DEPARTMENT.

To the Editor of THE LANCET.

SIR,—Please allow me space in your columns to inform intending candidates for competition for the Indian Medical Service that three of the men who took the highest places at examinations within the past three years have petitioned for transfer to the Army Medical Department, owing to the changes in their position and prospects under the late orders of the Government of India. More may have petitioned, but I know of three for certain, and it is only fair that candidates should be aware of the way that juniors look at the present position of their service before they find themselves in the same predicament. It has been a source of great disappointment and regret to our service to find THE LANCET, to whom we naturally looked for support in our struggle for fair play and justice, should have so misunderstood our case as to present to the public and the profession such a one-sided view of the points at issue; and, in the interests of common justice and fairness, I claim the publication of this protest against the idea put forward of there being either jealousy or animosity on the part of our service against the A.M.D. Nothing that has issued from our Defence Committee can be construed to bear such a meaning, though an occasional member of the service, smarting under the sting of injustice and degradation, may have written in a strain which he would himself be the first to regret in cooler moments, and I would assure our A.M.D. brethren that we repudiate all such ideas or intentions. They have succeeded in obtaining some crumbs of justice. No one considers they have obtained all they ought to have.

Now, all we claim is equality in our especial sphere of service. We do not see why 380 Bengal medical officers should be subordinated to 185 A.M.D. officers; the latter number being the war establishment of the A.M.D. in Bengal; in times of peace the number would be about 150 or so. You will reply, "Some of your men are under the civil department." True. But we are all military commissioned officers, and not civil officers, and are merely temporarily in civil employ, liable to be sent to military duty at any moment, and our promotions, pensions, and chance of honours or distinctions are all dependent on military service. Not a medical officer in civil employ has obtained a decoration or honour of any sort or kind in all Bengal! or I believe in all India, so that we are now practically and theoretically a subordinate branch of the A.M.D. So much then for our position; that is unquestionable.

As regards our prospects, which you assert have been improved, I would merely state facts. In 1860 there were seventeen administrative appointments (including a Director-General) in Bengal, which we could all look forward to as the reward of good service when our turn came. At the present moment there are three deputy surgeon-generals in the military department, for whom have been reserved the very worst and most unhealthy stations in Bengal, and on whose shoulders has been placed all the miscellaneous work of the Government, as gaols, sanitary, civil dispensaries, &c. &c. In the civil department there is one surgeon-general and sanitary commissioner combined, and four deputy surgeon-generals. Were the old and just rules of seniority and selection in force in this department, we could look forward perhaps to promotion in this line; but the two first promotions under the new rules have been from the grade of surgeon-major, superseding every administrative officer

in the service, and in both cases, in defiance of the hitherto unviolated rule, that officers who had once refused promotion, were not eligible in future. When such men as Deputy-Surgeons-General Christison and De Renzy—both men of acknowledged administrative skill and experience—were passed over, what can we hope for in future? What guarantee have we that the junior surgeon in the service, if he can only gain the ear of some local Lieutenant-Governor or the Viceroy, may not be appointed civil surgeon-general and sanitary commissioner? We have positively none, and will you, Sir, still say that our prospects are improved?

As regards the prospective promotion of the three sanitary commissioners to the privileges of deputy surgeon-generals. In the first place, they already draw the pay of a deputy surgeon-general, so there is no gain pecuniarily; they gain nothing in rank, except that their former commissions are to count from date of promotion, and not junior of that grade to the whole army, the Army Medical Department included; so the sole advantage lies in the pension of £250 extra. But how many of the sanitary commissioners will get it, and in what time? No sanitary commissioner since the post was created some fifteen years or so ago by Sir John Lawrence, as he was then, has yet retired as such, the Bengal and Punjab men having gone into other and more congenial appointments, as colleges &c., and Dr. Planck, the sanitary commissioner of the N.W.P. will have served as sanitary commissioner nineteen years before he can claim the pension of a deputy surgeon-general. Further, there is nothing to prevent any local Government appointing a military man or a competition wallah as sanitary commissioner, as has been done before, and the new rules in no way make the appointment a purely medical one. Under these circumstances I may, I think, be excused if I fail to see any reason for being grateful to Government. When the sanitary commissioners are ordered to be chosen from amongst the deputy surgeon-generals, I will admit the advantage; and when the latter are appointed for long service and efficiency, I may also be able to see some advantage in that line; but as long as they are the reward of toadyism, I cannot either look forward to the post or respect the incumbent.

I admit fully the absurdity of the late double administration. But why not have adopted the rule that has been adopted in the military commands—viz., every alternate man to be chosen from each service, and no distinction of stations to be observed? Or why not adopt the same ruling as in the Artillery and Engineers—equitable amalgamation? We are all proud of our service hitherto, and for this reason prefer to see it abolished to being degraded to a subordinate position under another service, whose members are less than half of ours, and whose standing is in no way superior. Again, let me repeat, we only ask for equality, and till that is granted, in a way, too, that cannot be set aside, let English and Irish students beware of how they put the yoke on their own necks.

I am, Sir, yours faithfully,

July 20th, 1880.

DISAPPOINTED.

* * We have received a note from the writer of the preceding letter, in which he informs us that, "if we [i.e., the Indian medical officers] fail, our service will attribute the failure to you chiefly, for the whole weight of your influence has been thrown into the scale against our obtaining our reasonable demands." Of this threat we will say nothing more than that we differ from the writer in his opinion as to what are reasonable demands. He admits the necessity for getting rid of the double administrative staff, but would like to retain half of the military appointments and to obtain all the new civil ones. We have considered it reasonable if the Indian Medical Department gets back a share, as it desires, of the military administrative appointments, that the British Medical Department should receive some compensation in the form of a share of the new civil ones, which were created to make up for the loss of the others. We do not think it reasonable that the British should lose more than half its administrative appointments without receiving anything in exchange, while the Indian should lose half and receive far more than an equivalent in the shape of lucrative civil appointments. In this respect we wish fair play to be given to both. We may add that on the same grounds we have always strongly advocated the revision of the scale of pensions for the Indian Medical Service, and the grant of rank and honours in it, to the same extent and on the same principle as in the British Medical Department.—Ed. L.

LIMITED LIABILITY COMPANIES AND THE PHARMACY ACT.

OUR contemporary, the *Pharmaceutical Journal*, takes a moderate and sensible view of the recent decision of the House of Lords in favour of Co-operative Stores and other Companies being at liberty to carry on the business of a chemist and druggist, provided that they do such business through a person who is properly qualified and registered under the Pharmacy Act. It would be a monstrous thing if such a Company were permitted to carry on such a business without complying with the conditions of the Pharmacy Act. Chemists and druggists, under these circumstances, should have little difficulty in competing with stores and companies. The public will be always likely to prefer the local chemist to the distant store, unless there is some great and unwarrantable discrepancy in the charges.

A General Practitioner had better apply to the Secretary of the Brussels Graduates' Association, Dr. Pocock, 20, Golborne-road, Upper Westbourne-park, W.

ERASURE OF NAMES FROM THE MEDICAL REGISTER.

We gather from our correspondents that the sharp application of the 14th section of the Medical Act, empowering the Registrar to write a letter of inquiry to any registered person, addressed according to the address in the Register, and in the event of receiving no answer within the period of six months from the sending of the letter, to erase the name of such person from the Register, is followed sometimes by much inconvenience and sense of hardship. It is most desirable, of course, to use all precautions for keeping the Register accurate; but the erasure of a name is a severe proceeding that should not be carried out till very strong evidence calls for it.

X. Y. Z. has forgotten to enclose his card.

POISONING BY THE CYTISUS LABURNUM.

To the Editor of THE LANCET.

SIR,—At the Ophthalmic Hospital of the West London District School, at Ashford, there are from twenty to thirty cases of slight granular eyelids. On the 6th inst., at about 12.20 P.M., shortly before the dinner hour, a number of the children were playing in a grass-yard used as a recreation ground, where there are some trees, one of which is a young laburnum tree. This tree was the victim of an assault, being broken down, and seven of the children ate and swallowed some of its leaves. The reciprocation of the attack was not altogether anticipated by them. The ages of the children only varied a few months; they are from six years and a half to seven years and a half of age. The first symptoms that attracted the nurse's attention were faintness and pallor. Upon the nurse interrogating them they confessed to having eaten some leaves of a tree, which was verified by the ejections, which were those of the laburnum. At 12.30 the children were seen by me, all of whom were in the same ward, except an unusually stout child, whose symptoms were not alarming after a few doses of ammonia and brandy. Extreme pallor; stupor; drowsiness; a weak, faltering pulse; coldness of the body and extremities; vomiting a clear fluid, containing portions of the leaves, and dilatation of the pupil in each case were symptoms common to all seven. Emetics were not given; indeed, they were contra-indicated, as vomiting had already set in, and the depression was extreme in most of the cases. The only reliable subjective symptoms elicited were pain in the epigastrium and frontal headache. Brandy, ammonia, and hot water were freely administered, and at 1 P.M. six cases had recovered, except drowsiness and partially dilated pupils. One boy was still in a serious condition; he was cold, although artificial heat had been resorted to, as in the other cases. The pupils were dilated; the pulse-rate 45 per minute and feeble; sleepiness; distressing retching, and a generally cyanosed appearance. Stimulants were freely given, but were quickly rejected by the stomach; nevertheless, they were persevered with, and at 1.45 P.M. reaction had been well established. They all partook of bread-and-milk at 5 P.M. The interest in these cases is that the children poisoned are all of the same age, with a variation of only a few months; that the poison taken was certain; that the poison was taken when fasting; that there was no diarrhoea; that there were no convulsions, not in the most extreme case; that the poisonous action of the laburnum is of a depressant and not of a convulsive character; and that recovery or death occurs in about two hours.

I am, Sir, yours obediently,

PETER W. DE LA MOTTE, M.R.C.P. Edin., &c.

Staines, July 13th, 1880.

Surgeon, R.N.—Yes. M. Lucas-Championnière has, we believe, recently performed the operation more than once with successful results.

Dr. M'Call Anderson.—Soon.

TREATMENT OF SCALP WOUNDS.

To the Editor of THE LANCET.

SIR,—If you think the following notes sufficiently interesting for publication, would you kindly insert them, as a comment upon the remarks of a similar case detailed in THE LANCET of June 26th :—

Mrs. P. B.—, an Irishwoman, aged sixty, was hanging clothes on the leads of her house. She fell a distance of forty feet into the yard of the adjoining house, striking in her fall the stone-sill of a scullery window. On arriving at the house, I found the patient perfectly conscious, with a large T-shaped wound, denuding the whole of the left parietal and occipital bones, the flaps of scalp covering respectively the left ear and the nape of the neck. After twisting two or three vessels and thoroughly cleansing the flaps, I inserted a thick wire suture at the junction of the two lines of wound, and applied very firm pressure with pads of dry lint and a bandage. This accident occurred on Nov. 12th, 1879. On the 14th the wire suture was removed. On the 20th, and therefore a week after the accident, the pad and bandage were removed. Union was perfect throughout. I saw one drop of matter in the course of my observation of the case—that was on the third day upon removing the suture. There was no œdema of face or bogginess of scalp.

Remarks.—The recovery was certainly remarkable; but I cannot attribute it to antiseptic dressings or the youth of the patient. I do attribute the result to hard and even pressure of the whole surface with dry dressings and non-interference for several days. Possibly something of the favourable issue of the case might be attributed to the nationality of the patient.

Yours truly,

FREDK. M. ROBERTSON, M.B., &c.

Colville-road, Bayswater, July 5th, 1880.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the 241 candidates at the final examination for the diploma of Membership of the above College on the 16th instant, when they were required to answer at least four out of the six questions, including one of the first two :—

1. Describe the relations of the thyroid body, and mention the various operations in which it may be directly or indirectly concerned.
2. Give a description of the fasciæ of the male perineum, and state the chief surgical inferences to be drawn from their anatomical arrangement.
3. Under what circumstances in injuries of the head would you consider trephining indicated? Describe the operation.
4. Describe the ordinary consequences of dissection wounds, and the appropriate treatment.
5. Give the clinical history of a case of caries of the tarsus, and describe the pathological changes which occur in the course of the disease and in the subsequent repair.
6. To what causes may converging strabismus be due? Under what circumstances would you consider an operation appropriate and how would you perform it?

The following were the questions on the Principles and Practice of Medicine submitted to the candidates on the following day :—

1. Discuss the morbid anatomy and symptoms of enteric fever, and state the chief clinical distinctions between it and tubercular meningitis.
2. What are the distinctive signs of the several diseases of the aortic and mitral valves? What are the consequences of mitral disease as regards (1st) the heart itself; (2nd) the pulmonary circulation and lungs; and (3rd) the general circulation together with the liver and kidneys?
3. Enumerate the official alkaloids and their several preparations. State whence they are derived, what are their physiological and medical properties, and what their doses.

VENTILATION OF HOT-AIR BATHS.

To the Editor of THE LANCET.

SIR,—In view of your seasonable warning in THE LANCET of June 5th, regarding the dangers from insufficient ventilation in Turkish baths, allow me to mention a mode of ventilation that, so far as I know, is, of all modes, the most simple, cheap, and effectual. It applies to baths heated by a stove burning within the room, as in the case of baths heated by means of Scriven's circular stove, now in general use. All that is required is to cause the air that feeds the stove to traverse the room, slowly but continuously, in order to reach it. Of course combustion cannot go on in the stove without a continuous supply of air containing a due amount of oxygen. If air from the outside were allowed to enter near to where the stove is placed, it would reach it by a direct short cut, and could do next to nothing to change the air in other parts of the room; but if the air could enter only, or chiefly, on the side of the room opposite the stove, and had consequently to traverse the room in order to reach it, the slow-moving current would carry with it the carbonic-acid gas from the bather's lungs, which is the chief impure gas to be got rid of. The minute openings required for the entrance of air should be high up in the walls, or, better still, in the roof. This prevents all sensation of cold draughts among the bathers. The air from the outside, even in summer weather, is colder, and consequently heavier, than the air in the bath. It quickly becomes partially heated by meeting the radiation from the stove, and by mixing with the hot air, already of a high temperature; but it is not rarefied so quickly as to prevent it from sinking slowly towards the floor, moving along which towards the stove it carries with it the carbonic-acid gas. It is obvious that this gentle movement must be continuous so long as the fire in the stove is kept up, and that the more energetically the fire burns, the better will the ventilation of the apartment be. It is equally obvious that roof ventilation cannot be depended upon for the removal of carbonic-acid gas, because, being heavier than pure air of the same temperature, it cannot ascend except in minute quantity, on the principle of diffusion of gases. Much has been written about the admission of pure air into rooms, and many seem to take for granted that, if provision is made for this, all will be right. The object, however, that should be most considered is the removal of the gas thrown off by the lungs, and provision must be made for this at as low a level as where the heads of the inmates are.

The principle I have mentioned is applicable to ordinary dwellings and to all places in which fire is kept burning. In building a house, or in buying or renting, a chief thing to be seen to is that the relation of the fire-place to doors and windows is such that the air that feeds the fire must traverse the apartment in order to reach it. Many otherwise excellent houses are faulty if judged by this principle; but anyone that bestows attention upon it must see at a glance its great importance.

Yours &c.,

A. M.

July, 1880.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—The Bradford Chronicle and Mail of June 12th, 1880, contained letter signed "A Woolsorter," in which my name was mentioned. I wish respectfully to state that I am utterly ignorant of its author, and that I have not in any way whatsoever had anything to do with its insertion.

I am, Sir, yours faithfully,

Heckmondwike, July 27th, 1880.

FRAS. B. LEE.

A HAPPY TERMINATION.

THE *Canada Lancet* reports that a suit for malpractice in a case of arm fracture, in which damages for \$10,000 were claimed, was recently instituted against two Baltimore surgeons. Dr. Walls, one of the defendants, gave an account of the case and of its treatment so clear and convincing as to induce the plaintiff and the counsel to make a public apology and to withdraw the suit.

Secretary, Order of St. John.—The lecture was noticed in our last issue.

MEDICAL AND SURGICAL BED-DRESS.

To the Editor of THE LANCET.

SIR,—When writing some suggestions for a "Medical and Surgical Bed-dress," I was not aware that [Dr. Thomas Joyce of Cranbrook had previously made a similar suggestion for "A New Form of Bedgown for Sickness," in the *Practitioner*. So far as the principle of our two communications is concerned, the original idea was clearly due to Dr. Joyce, and I hasten to acknowledge this. Had I known of Dr. Joyce's communication in time, I need hardly say I should have referred to it in my own "suggestions."

I am, Sir, yours &c.,

H. CRIPPS LAWRENCE, L.R.C.P. Lond.

Oxford-terrace, W., July 22nd, 1880.

A PRIZE FOR A "GOOD" MEDICAL ASSISTANT.

THE following letter to an applicant for an assistantship will be read with interest:—

"DEAR SIR,—Mr. — desires me to say his terms are to good married man a permanency. Salary 30s. weekly, unfurnished house, gas down stairs (not up), 1s. in the pound commission instead of coal, increased to 2s. in the pound when 45 is reached. There is no midwifery nor bookkeeping nor nightwork. It is on the dispensary system, all ready money. He requires bond signing, and pays no travelling expenses. Mr. — has a number of these places in —. He will require reference as to sobriety &c. to last situation. I enclose you carte.

"Yours &c.,

" — — —"

ERRATUM.—In Mr. Herbert Page's letter on Colour-blindness, page 152, line 23 from top, for "watching" read *matching*.

Clinical Lecture

ON A

CASE IN WHICH NUMEROUS GALL-STONES
WERE DISCHARGED THROUGH A
FISTULOUS OPENING IN THE
ABDOMINAL WALL.*Delivered in King's College Hospital, May 11th, 1880,*

By I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—I have enumerated the various ways in which biliary concretions may escape from the gall-bladder and the biliary passages, and the case to which I now wish especially to direct your attention is one in which the gall-stones have been discharged in a somewhat unusual manner—viz., through a fistulous opening in the abdominal wall. I show you here between seventy and eighty gall-stones which have been discharged by my patient in this way. Over a hundred have been discharged altogether; twenty-five of these, however, were removed by an operation the particulars of which I shall immediately detail. You will observe that these concretions are faceted as gall-stones usually are when they are numerous. They vary in size from that of a hemp-seed to that of a large pea; they are of a brownish-yellow colour, and on section they display the ordinary structure of gall-stones—viz., a dark, almost black, nucleus, surrounded by a light brown “body” and an external crust.

This patient, a married woman, a dressmaker, fifty-six years of age, was admitted into the hospital on the 24th of last October. She had occasionally come under observation from time to time as an out-patient during the previous five years, and was looked upon as a rather troublesome nervous woman, with dyspeptic symptoms. She used to complain of pain and flatulence after food, with occasional vomiting, but had never, while attending as an out-patient, presented any signs of jaundice, nor had she ever complained of attacks of acute pain such as occur during the passage of gall-stones. She states now, however, that she remembers an attack of sudden pain in the hepatic region so long ago as 1873, and that this was associated with slight jaundice of the conjunctivæ and skin. She also states that in February of last year she had a severe attack of jaundice, during which she kept her bed for two months. For the first fortnight of this attack she suffered great pain, and the motions were quite white, then the pains diminished and disappeared, but the discoloration of the skin remained for some months, so that this patient may have discharged gall-stones in the ordinary way for some years. Last August she first noticed a swelling in the lower part of the abdomen on the right side, which she was ordered to poultice. She had suffered much pain while it was forming. In September this broke, and discharged “blood and matter,” and the day after four gall-stones came away through the opening, their passage being attended with much suffering; *fifty-one* concretions came away in one week, and as many as *twenty-one* in one day. She had passed, on her admission, *sixty-one* gall-stones altogether, and she passed *seventeen* more during the first fortnight of her stay in the hospital. On analysis, they were found to be composed of cholesterin and bile-pigment.

On examination of the abdomen, on her admission, an external opening low down on the right side in the abdominal wall was found, situated in the hypogastric region, about three-quarters of an inch from the median line, and about five inches below the umbilicus. It was discharging a considerable quantity of glairy mucus, not unlike the white of egg. A deep inflammatory blush, at this time extended for a considerable distance around the opening. A probe introduced into the opening passed readily for six or seven inches upwards and to the right, where it apparently came against and was arrested by a hard mass, which could be felt through the abdominal walls, and grasped, as if it were the fundus of a displaced and distended gall-bladder; while,

extending downwards from this, and following the course of the sinus, was an extensive mass of inflammatory induration.

No discharge of anything like bile had ever been observed from the external opening of the sinus. The few biliary calculi that were passed soon after her admission were passed without any suffering; and with rest in bed and appropriate treatment the inflammatory condition of the integuments around the sinus rapidly subsided. Her constitutional condition was good; tongue clean; appetite fair; some tendency to constipation; urine normal. There was no enlargement or tenderness over the liver, or in the natural situation of the gall-bladder.

On Nov. 7th Mr. Lister was good enough to see the patient with me, and, as we thought there might be many more calculi accumulated in the hard mass at the end of the sinus, and which might possibly be the displaced gall-bladder, Mr. Lister proceeded to dilate the passage rapidly by means of large-sized metallic urethral dilators. This was done twice, but without any marked result; one or two small calculi continued to be passed at intervals.

The patient continued without much change until the middle of February. Several weeks had elapsed without the passage of any more calculi, and, as the sinus still continued to discharge a considerable quantity of the glairy mucus I have before described, it was determined, after consultation with Mr. Lister, that he should slit up and explore the sinus.

On the 16th February the patient was put under chloroform, and a large probe being passed along the sinus as far as it could go—viz., between five or six inches,—the thickness of the abdominal wall between the surface and the sinus was cautiously divided, the cut extending from the orifice of the sinus upwards and outwards towards the somewhat globular mass situated about midway between the costal margin and the crest of the ilium. In doing this a considerable thickness of the abdominal wall had to be divided, the wound extending nearly down to the peritoneum. About twenty calculi were dislodged from along the tract of this sinus, and the round mass before described appeared, so far as we could judge, not to be the gall-bladder, but merely the result of inflammatory induration. On carefully examining the sinus now it was exposed, a small diverticulum to the right admitted of the passage of the probe for about an inch and a half. This was slit up, and five more calculi discovered, so that five-and-twenty biliary concretions in all were found infiltrated, as it were, in the abdominal wall, and were removed by this operation.

The wound, which was a large one, was dressed with glycerine and carbolic acid, and the patient removed to bed. The patient bore the operation extremely well. The next day the temperature rose about one degree, soon to fall again to normal. A faint putrid odour was given off by the wound for a few days, but this disappeared and the wound steadily filled up. It is now nearly quite healed. There has been no further discharge of gall-stones and no complaint of pain, and the sinus appears completely closed.

There are many cases on record of the passage of gall-stones through fistulous openings in the abdominal walls, and they have nearly all occurred in the persons of women of middle or advanced age, like our patient, who is aged fifty-six. The process which leads to the formation of these fistulæ is usually as follows:—The ulcerative inflammation set up in the gall-bladder leads to adhesion of the superjacent abdominal wall, and the ulcerative process “eats its way through the adherent abdominal wall till it reaches the surface.”

We may suppose that in this case the gall-bladder had become distended by a vast accumulation of biliary calculi. Some of these had from time to time escaped in the usual manner, along the common bile-duct into the intestine; the passage of the smaller ones giving rise to no suffering, the passage of the larger ones being attended with the symptoms of biliary colic, which this patient appears to have suffered at least twice, at long intervals. Then, probably, one larger than its predecessors became impacted in the cystic duct, and set up inflammation which led to the closure of the duct. Subsequently the inflammatory and ulcerative action extended through the coats of the gall-bladder and the adherent portion of the abdominal wall. A number of gall-stones then made their escape, and became as it were infiltrated into the abdominal wall, working their way downwards between its layers, and giving rise to fistulous tracts, and setting up a great amount of inflammatory thickening

and induration around, and finally discharging at a point low down on the abdominal surface, no doubt quite remote from the seat of the original opening in the gall-bladder, which may have become completely closed before the formation of an external wound. So that in this case, as in most others of the kind on record, the cystic duct must certainly have become closed before the formation of the fistula in the abdominal walls.

The discharge, after the first rupture of the superficial abscess, has always been that of white, glairy mucus. We thought, for some time, that this discharge proceeded from the mucous membrane of the gall-bladder itself, which we imagined was in direct communication with the fistulous tract, and on that account we hesitated long before having recourse to any operative procedure, for we thought that if we were to divide the fistula as high up as we could go we should still have remaining behind the discharging inner surface of the gall-bladder. But as the discharge still continued undiminished in quantity, and as it was a perpetual nuisance to the patient, and as it seemed probable, if she were allowed to leave the hospital, inflammation would again set in around the sinus and its opening, and as we considered that if we divided the sinus as far as we could we should certainly leave a less extent of discharging surface, and bring the external opening much nearer the source of the gall-stones, if there were any more to pass, as seemed most likely, and as the patient herself was very anxious that something should be done, Mr. Lister divided the sinus, as I have told you. It was an operation of some importance, for the sinus ran for some distance five or six inches, and was deeply situated in the abdominal wall about an inch and a half from the surface, and was, therefore, very near the peritoneum. A gall-stone was found impacted at the end of the main sinus, and then beyond this several more; five and twenty, and some fragments, altogether being removed from the main sinus and a diverticulum from it. The success of the operation has been complete. No further gall-stone has been passed, and there is now no more secretion, the wound appearing completely healed, so that we hope to be able to discharge the patient from the hospital in a few days.

The issue of the case has been a very fortunate one. The patient is not likely to have any further trouble from biliary calculi, and the operation has relieved her from what was, though not a painful, yet a very distressing, state of affairs—viz., a constant and profuse discharge from a fistulous opening in the abdominal walls.

Lectures

ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE I.—PART I.

TUMOURS OF THE TESTIS.

MR. PRESIDENT AND GENTLEMEN,—As the first Erasmus Wilson Professor of Pathology under the new conditions of the trust, the duty devolves on me, which I cannot but regard with pleasure, of expressing, so far as I can do so in words, the feeling of gratitude which must animate all those who are working in the great field of pathology towards the founder of this chair.

The act, generous in itself, is rendered yet more graceful by his permission to deflect the endowment from the purpose to which it was at first devoted to one which cannot in the nature of things be so dear to him as the encouragement of his own favourite study of dermatology. I trust, however, that Mr. Wilson may be in some sort repaid by the impetus which will certainly be communicated to the study

of pathology and by the knowledge that through his means this impetus has been conveyed.

A classification of tumours may be based either on their anatomical or clinical characters. At the present time the former is nearly exclusively employed and the clinical classification has fallen almost entirely into disuse. Nor is this, I imagine, solely due to the influence of fashion, although I am aware she exercises even in pathology considerable sway. But the anatomical classification is preferred because it is more scientific and is more in accordance with the methods which are adopted in arranging plants and animals, methods from which the best results have been obtained, and by which our knowledge of these things has probably been much increased. It cannot, of course, be maintained that the anatomical classification is perfect, or that it fulfils every purpose for which it was designed. To judge justly of its merits, however, it must be compared, not with some ideal method, but with the method it has succeeded in replacing. I think it will be admitted that a classification, on whatever basis arranged, should be consistent or should at least be capable of being made consistent; and, as a corollary of this, that classification must be the best of which every part is in harmony with every other part, and all whose parts are in harmony with the principle on which the classification is arranged.

In the "Nomenclature of Diseases" drawn up by a Joint Committee of the College of Physicians in 1869, tumours are arranged according to what is understood as the clinical method. The great primary division is of all tumours into malignant and non-malignant. Of the malignant growths the scirrhus and medullary varieties are so formed on the ground of their clinical characters; but the definition of the variety epithelial cancer admits that the cancer is "characterised by the resemblance of its cells to those of epithelium." So slight a deviation from the guiding principle, however, might be pardoned, but the non-malignant tumours are subdivided according to the likeness each presents to some natural texture of the body, as fibrous, fatty, osseous. And among these, with an inconsistency more striking still, are found varieties which depend upon their microscopic structure, the fibro-plastic and fibro-nucleated tumours, which, clinically, are more than half-malignant, and anatomically cannot be distinguished with the naked eye. I say "cannot be distinguished with the naked eye" not on my own authority, but on that of Dr. Bennett,¹ who, speaking of the fibro-nucleated canceroid growth, uses these words, "I know of no means of distinguishing it except by a microscopic examination, as sometimes the growth exactly resembles scirrhus, at others encephaloma." And Sir James Paget,² describing the recurring-fibroid tumours, which are included with the fibro-plastic, makes one of their chief characteristics the resemblance of their general aspect to that of the common fibrous tumours.

Here, then, is a classification purporting to be clinical but of which more than half the classes are based upon other than clinical grounds, some of them upon the gross or rough anatomical appearances, others of them upon the microscopic characters. I should not deem it necessary thus to criticise a method of arrangement which was most valuable thirty years ago, and under which, or perhaps in spite of which, the study of oncology made rapid strides, but the loss of it has been made a subject of deep and wide-spread lamentation, exceeded only by the indignant scorn with which its successor was received.

Now, whatever may be said against the anatomical classification on the ground of imperfection or of uselessness at the bedside, it cannot be reproached with being generally inconsistent. Its inconsistencies are few, and those which yet remain are gradually yielding before a wider knowledge of the subject and clearer insight into the nature of certain doubtful groups. Most of the groups of non-malignant tumours have been transferred unchanged to corresponding groups in the new system, but the difficulties experienced in arranging the malignant and semi-malignant tumours have not yet been wholly overcome. Virchow,³ discerning certain structural characters common to the fibro-plastic,

¹ On Cancerous and Canceroid Growths (Edin.), 1849, p. 176.

² Lectures on Surgical Pathology (London, 1853), p. 155.

³ Krankhaften Geschwülste, Band ii.

recurring fibroid, and fibro-nucleated tumours, gathered them into a single class, with such other growths as presented similar characters, and called the class sarcoma. Sarcoma, as defined by Virchow, was a tumour of the connective-tissue series characterised by an excessive development of cells. But Virchow's carcinoma was also a tumour of connective-tissue origin, and often presented a preponderating growth of cells. It was therefore impossible in many instances to distinguish between sarcoma and carcinoma. I will not weary you with a detailed history of various efforts made to overcome this difficulty, of minor differences discovered between sarcoma and carcinoma, some of them useful and still used, but none of them sufficient, until at length Waldeyer⁴ succeeded in tracing carcinoma to an epithelial origin. This theory of carcinoma, worked out with an admirable sagacity, has formed the basis of all succeeding investigations, and although it has been ably contested and has been made a subject of frequent debate, free ventilation has only served to strengthen its position and to render it generally received. I accept without reserve this theory of the epithelial origin of carcinoma, in part because, to me, Waldeyer's reasons appear sound and his conclusions just, but chiefly because I have myself been so fortunate in certain varieties of carcinoma as to trace as clearly as may be the process by which a carcinoma is developed from epithelial cells. It is right I should here refer to the more advanced attempt which has been made to classify these tumours, in accordance not merely with the form but with the origin of the tissue from which they grow. Whether this will be possible in the future I do not know. But at present I shall not adopt it, first, because I do not see what object is by its means attained, and, second, because I am sure by its use much confusion would be produced. For example, the whole testis is said to be derived from the mesoblast. Even its epithelium, therefore, according to this view, is incapable of developing a carcinoma.

I shall then define carcinoma to be a tumour of epithelial origin, having generally an alveolar structure, and sarcoma a tumour of connective-tissue origin, formed generally of embryonic tissues, and without alveolar structure. And for minor differences the cells of carcinoma generally resemble those of the epithelium from which it grows; there is little intercellular tissue; the vessels run in the fibrous tissue, not among the cells, and multiplication of cells is by endogenous formation. On the other hand, sarcoma is composed of round, or fusiform, or giant-cells, and these are packed in a more or less abundant basis; the vessels are often mere fissures between the cells, and the cells increase in number by division. These minor characters are common, but they are not constant. One or other of them may be absent in a tumour of either class, or, worse, may be present in a tumour of the other class. More commonly it is sarcoma which thus simulates the appearance of carcinoma, but, fortunately, this feigning takes place most often in textures where there can be no question of the origin, and therefore of the nature of the tumour. The alveolar structure found in some sarcomas is rarely so perfect as that of most epithelial tumours; indeed, careful study discovers that the tissue which surrounds the alveoli is generally formed of spindle-cells. There is in most cases no real difficulty in assigning each tumour to its class. But where the characters which should be distinguishing are not clearly marked, and the origin cannot be ascertained, the tumour must be left unclassified. Although little can be said against the anatomical method of arrangement, much objection may be fairly made to its nomenclature. The terms hard and soft still applied to varieties of carcinoma, even the words carcinoma and sarcoma themselves, are an offence against a rigid system of anatomical nomenclature. The powerful influence of long usage, and the difficulty of discovering and agreeing upon efficient substitutes, are the only reasons which can be given for still continuing to employ them. It appears to have been expected that if the structure of a tumour can be so clearly made out that it can be referred, not only to class, but to sub-class or group, its whole course and tendencies ought immediately to be discernible—an impression which I imagine arose from the almost unvarying course of many of the fibrous, fatty, or osseous tumours, and from the malignancy of most of those which are truly cancerous—a malignancy which nevertheless is liable to the most singular variation. And great disappointment has been felt that

this expectation has not been realised, nay, has been so little realised that it cannot be asserted of any case of sarcoma from a knowledge of its structure whether or not it will recur, or will affect the lymphatic glands, or in what direction it will become generalised.

The objects of the present inquiry are to discover how far the course of a tumour can be predicted from a knowledge of its intimate structure, whether there really exists so little or so large a difference as has been asserted between sarcoma and carcinoma, and whether in a doubtful case the microscope is likely to be truly useful. Of course I am aware that many general and special text-books on pathology contain accounts of these tumours, and of their supposed tendencies. My excuse for adding one more to these accounts is—first, that most of them were written before the modern method of arrangement and manner of preparing sections permitted their authors to collect a sufficient number of unquestionable cases for the purpose of comparison; and next, that I shall investigate the subject in a different manner to that which is commonly adopted, and shall study not so much similar tumours of different tissues and organs as different tumours of the same tissue or organ, by which means I hope a more correct idea may be obtained of their relative course and tendencies. Even now the number of cases gathered from my own experience at St. Bartholomew's Hospital, and from published records, is not so large as I could wish; for many have been rejected of whose accuracy I could not feel assured in order that the truth of the inquiry might be as little as possible prejudiced by falsity of the details on which it is founded. Among other difficulties by which I have been met one is due to those transformations of their substance so common in many tumours, which render their original structure a matter of conjecture. In such cases I have been guided chiefly by the nature of their softer and more recent parts, and have often been much assisted by a study of any secondary tumours which were present.

In to-day's lecture I shall compare tumours of the testis; and in the two following lectures tumours of the bones. Of course, these are only parts of a much larger study, comprising indeed the whole pathology of carcinoma and sarcoma, but I hope each part will be so far complete that, should the inquiry be arrested at any point, what has been finished may be found not altogether useless.

The testis may be the seat either of sarcoma or carcinoma. The former appears to originate in the connective-tissue walls of the tubuli seminiferi or in the tissue between the tubules. The new growth increasing, gradually separates the tubules more widely from each other, and at the same time diminishes their calibre and destroys their natural form. But for a long time, even in tumours of large size, tubules can still be recognised scattered at irregular intervals through the growth, perhaps still lined with epithelial cells or with the remains of epithelium. The new tissue generally takes the form of vast numbers of round cells imbedded in a somewhat scanty basis substance, often traversed by fibrous tissue, and not uncommonly exhibiting a delicate reticulated structure; or of fusiform or spindle cells arranged in the form of trabeculae, which interlace, join, and cross each other at various angles. Sometimes, mixed with either of these two forms, there occur stellate cells in a viscid or hyaline basis, or hyaline cartilage may be found forming either a kind of framework through the growth or perhaps a large portion of its bulk.

Carcinoma is a growth originating in proliferation of the epithelium of the gland. Its alveolar structure is generally pronounced, its cells increase in number by endogenous multiplication. I have not myself been fortunate enough to trace the development of carcinoma from the tubules of the testis, but this has been done by Birch-Hirschfeld⁵ in a testis the cancerous tumour of which was still surrounded by a thin layer of the tissue of the gland. In this layer existed a series of transitional forms from an almost normal tubule to the fully-developed alveolus of the carcinoma. The changes were effected mainly by the action of the epithelium, the cells of which multiplied, filled, and dilated the tubules, and thence spread into the surrounding tissue. The only form of carcinoma with which I am acquainted is the soft variety. Nor have I found on record any authentic case of hard carcinoma of the testicle. Three cases are mentioned by Mr. Curling,⁶ but they do not appear to have

⁶ Diseases of the Testis, 4th edit., chap. viii. London, 1878.

been examined with the microscope. Manoury's⁷ celebrated case, of which Nepveu made the examination, was, I cannot but think, a fibrous sarcoma. For the fibrous tracts radiating forwards fanlike from the body of Highmore suggest hypertrophy of the fibrous partitions of the gland; the fine mesh-work in the alveoli is not indicative of carcinoma; and the wide tracts of connective tissue separating compressed and atrophied tubules are appearances characteristic of sarcoma, not of carcinoma. Kocher⁸ states that cartilage occurs in carcinoma, and that the combination is more frequent than that of cartilage with sarcoma. I can scarcely understand the source whence this conclusion is derived, for in the cases of carcinoma drawn from my own experience, and from the records of surgery searched through many years I have not found a single case of carcinoma containing cartilage. Judging from analogy, too, the combination is not one we should expect.

Of the course and characters of most cases of sarcoma and carcinoma a single description might suffice, for with certain exceptions, to which I shall presently refer, there are no means by which we can distinguish between the two diseases. Let me illustrate their general course by certain cases in which the salient features are exhibited of each disease, if not all of them, some, at least, of the most important in each case.

First of carcinoma.

A German student, single, twenty-one years of age, whose case is very fully related by Birch-Hirschfeld⁹ in the *Archiv der Heilkunde*, first noticed swelling of the left testis in 1866. He could assign no cause, venereal or other, for the enlargement, and could remember no squeeze or hurt. For a while the affection seemed to grow less, or at least not to increase; and in the early part of 1867 it had made so little progress that he was considered fit for active military service. But in the spring of 1867 he was again examined, when the testis appeared as a tolerably firm tumour, perhaps as large as a small egg, smooth, and free from pain. From this time, its growth, although not rapid, was continuous, and the tumour attained a considerable size. In February, 1868, he could no longer walk or even move about, but was obliged to retain his bed on account of swelling and oedema of both legs. These symptoms were shortly followed by manifest enlargement of the liver, and in May he died. At the autopsy the tumour was the size of a child's head, but by the evacuation of eight ounces of fluid from the tunica vaginalis its bulk was much diminished. It was at no part ulcerated, or even adherent to the scrotum. The cord was greatly thickened below, but the increase in its size became much less before it entered the abdomen. When laid open the tumour presented a perfect specimen of encephaloid cancer. The epididymis was changed in like manner as the testis. At first all the normal structure of both appeared to have been destroyed, but examination left no doubt that opposite the corpus Highmorei a thin layer of gland-structure covered the surface of the tumour. The right testis was sound. The inguinal, pelvic, and lumbar glands formed a large cancerous mass occupying the left side of the pelvis and abdomen. The liver was much enlarged, and very full of secondary growths, many of which were of large size. Both lungs contained secondary nodules, but neither in size nor number could they be compared with those of the glands or liver. I have already spoken of the minute structure of the tumour, for it is that in which Birch-Hirschfeld succeeded in tracing the process by which alveoli are formed from the tubules of the gland. Only in one particular does this case deviate from what may be regarded as the type of carcinoma of the testis. The patient was younger than the age at which the disease most commonly occurs.

A dyer, thirty years old, married, the father of five children, the youngest of whom was but two months old, noticed two years before he was admitted to the hospital that his right testis was the size of a hen's egg. He could not account for this circumstance, and apparently thought little of it; but the tumour continued regularly to enlarge, until at the end of a year it was tapped and six ounces of bloody fluid were removed. Six months later the tapping was repeated, but only a few drops of blood issued through the trocar. Although the tumour attained a considerable size, and was therefore wearisome by reason of its bulk and weight, it caused the patient very little pain. He was a thin, anæmic man, with a huge tumour occupying the posi-

tion of the right testis—a tumour of oval form, fourteen and a half inches in circumference, quite smooth, elastic, tense, firmer below than at the upper part. The scrotum could be raised with difficulty off the surface of the tumour, and the superficial veins were tortuous and full. The disease extended high up along the cord, which appeared, however, to be of normal size before the internal ring was reached. Deep down in the abdomen, on the same side, firm masses of irregular form could be distinguished. To relieve him of the encumbrance, but only as a palliative measure, Mr. Langton performed castration. During the operation some twenty ounces of clear yellow fluid were drawn off. The tumour, the fibrous tunic of which was still unbroken, consisted of a central, soft, dark fawn-coloured pulp, surrounded by a firmer substance of the same fawn colour. No trace of the secreting structure of the testis or of the epididymis could be discerned. Immediately above the tumour in the cord was a second smaller mass of like colour and consistence, but above this mass the cord seemed natural. The microscope revealed an alveolar structure, the alveoli of which enclosed large round or ovoid cells, resembling greatly the epithelium of the gland. Five days after the operation symptoms of peritonitis were observed, and with these symptoms ten days later the patient died. No post-mortem examination was permitted—a twofold misfortune; for, first, its absence destroyed the completeness of the case so far as the cancer is concerned; and second, the cause of the inflammation of the peritoneum must remain for ever uncertain, since nothing occurred during the operation by which it could be accounted for.

As examples of sarcoma to compare with these the following may serve:—

In November, 1876, I received a tumour of the testis from Mr. Lant Smith, of Alcester, with a note to the effect that it had been the day before removed from the scrotum of a child six years of age, who had come under his notice about six weeks previously. It was uncertain when the tumour first began to grow, but during those weeks it had increased one-half in size. Mr. L. Smith added, "there is some uncertainty about the paternity of the boy, but a reputed father died last year from cancer of the liver. The husband of the mother is living, which renders it difficult to establish the paternity." The epididymis and body of the testis were both affected, but the cord was not involved. The tumour measured, after removal, 3 in. by 1½ in. Externally its surface was quite smooth and unbroken, on section white and homogeneous, but intersected by faint fibrous bands. Its consistence was firm and equal. Everywhere the normal structure of the testis was replaced by spindle cells and coarse fibres, with which were mingled confusedly round or oval cells, granular, and of large size. Diagrams of enlarged copies of the microscopic structure, the one as seen with a low power, the other more highly magnified, both accord in an entire absence of alveolar structure.

The boy recovered from the operation, and until July of last year (1879) I heard no more respecting him. Mr. Smith then wrote to tell me that his patient was at the point of death. His abdomen was occupied by a large tumour, extending from the right inguinal region to the cartilages of the ribs, and by a second smaller mass in the situation of the spleen. The larger tumour had first been noticed fully two years previously, some six or eight months therefore after castration was performed. The second tumour was of recent growth. A few days later the patient died, when, to our chagrin, his mother's husband, who had learned to entertain for him the affection of a father, could not prevail upon himself to permit him to be opened.

In almost every point this case corresponds with most cases of sarcoma of the testis in children, particularly in its somewhat confused structure and absence of cysts or cartilage, in its rapid growth and in the secondary affection of the lymphatic glands, for that I imagine was the nature of the tumour which reached from the groin to the costal cartilages. So little doubtful does this appear to be that I would even venture to deduce from it a lesson teaching of the slow progress of glandular disease, its mild action on the economy, perhaps even its power of withholding, for a period, generalisation by the blood.

A case equally characteristic of its kind, but differing widely from the last, is that of a wood-sculptor, fifty-seven years of age, who was castrated by M. Trélat in February, 1876. His case is related by Letulle,¹⁰ and I use it in

⁷ Gazette Hebdom., 1871, p. 640.

preference to one very similar which I myself observed, because it is somewhat more complete. The man was the father of fourteen children. At twenty years of age he was exempted from military service on account of a slight affection of the left testis, probably only varix. With that exception he had ailed little until seven or eight years before he came under observation, when the scrotum was found to be enlarged. The growth was very slow until the last six months, but from that time became just as rapid as it had previously been slow. Before removal the testis presented the shape and size of a large kidney, a contour tuberoso or bossed, a consistence very unequal. The scrotum was not adherent, and the cord was scarcely thickened. On section the tumour contained no cysts or softened portions; its upper part was firm and white, its lower tinged with red and lobed. No separation existed of the body from the epididymis. In thin sections from various parts seminal tubes could be discerned, altered in shape, nearly deprived of epithelium and separated by adenoid tissue, of which the tumour appeared entirely to consist. Shortly after the operation the right testis became enlarged, two months later tumours formed beneath the integument of various regions of the body, and in September the patient died. The disease was widely generalised. The cicatrix of the operation was indurated and the structures of the cord were separated by new growth; the right testis was much enlarged and hard; the inguinal, pelvic, and lumbar glands were infiltrated; and secondary growths occurred in the sternum, vertebræ, bones of the skull, and in the subcutaneous tissue. The tumours most superficial were ulcerated, and ulceration was observed of some portions of the small intestine, although no thickening of its coats about these ulcers was apparent.

NOTES OF A CASE OF HYSTERO-EPILEPSY

By DR. MCCALL ANDERSON,

PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW

IN THE LANCET for July 12th of last year I reported a typical case of hystero-epilepsy, illustrating not only the symptoms of the disease, but also the effects produced by the application of various metals, magnets, and solenoids to the surface, as well as the influence of the internal administration of the acetate of lead in modifying the symptoms.

The case which I am about to relate presents most of the symptoms observed in the last, although the epileptiform seizures occupied a much more subordinate place, but it differs from it in that the patient suffered in addition from partial hemiplegia, from irritation of the spine, and from phantom tumour of the abdomen; while the results of various applications to the surface were somewhat different, and calculated in some respects to support the theory of expectant attention as the cause of the phenomena.

This patient, a married woman twenty-eight years of age, was admitted into the Western Infirmary under my care on the 22nd October, 1879. She had been formerly (15th March, 1877) in the wards of one of my colleagues, and from the ward journal the following particulars were gathered. She complained at that time of pain in the iliac and hypogastric regions, especially the left. The abdomen also was very much distended, the enlargement being uniform and extending even up to the sternum; and the abdominal walls were very tense. Up to the age of sixteen she enjoyed good health, but at that time she had inflammation of the left lung, and since then has never been very strong. When recovering, she menstruated once for the first time; she did not menstruate again for a period of two years, and since that time the monthly discharge has been very irregular. At the age of eighteen the abdominal swelling was first observed, and she has been troubled with this on and off ever since. When between twenty-three and twenty-four years of age she received a kick from a horse in the left iliac region, the pain from which was relieved by the application of leeches. Six months thereafter she was married; and about a year after that, and three weeks after having been kicked on the abdomen by her husband, she had a miscarriage, and since then she has never been free from pain. She also complained of a choking sensation in the throat at

times, and suffered occasionally from severe headaches; and when she was in the infirmary on the first occasion she had four fits, which were believed to be of a hysterical nature. She had sometimes, too, attacks of sickness and vomiting. She remained for about three months in the hospital, and improved somewhat, but not materially.

On readmission on the 22nd October, 1879, she presented most of the symptoms above mentioned, with the following additions:—Her bowels have long been very costive, and now she is never moved without medicine. She has frequently difficulty in making water, and at times the catheter has to be used. She has also, in great measure, lost the power of the left lower extremity, which she attributes to an inflammation of the calf of the left leg, which set in in the winter of 1877, which was accompanied by much pain and swelling, and which lasted about six weeks. She has had to use a crutch ever since.

She was a healthy-looking, well-nourished woman. There was no fever, but her appetite was indifferent. She had occasional attacks of nausea and vomiting, and her bowels were so costive that she often passed a week without a motion. It was with difficulty that we could get her to speak at all, and then only in a whisper. She wept readily, was bashful, and could not look one in the face; in fact, she had the typical appearance of a hysterical female, as might have been anticipated from the history just given.

The left arm was found to be weaker than the right, and on squeezing the dynamometer with the right hand it registered forty kilogrammes, while with the left she could make no impression upon it at all. The left lower extremity was much more decidedly paralysed, and when she walked she dragged her foot after her. This limb also was stiff, and the foot strongly extended. There was very slight wasting of the muscles from disuse. The electro-muscular sensibility was very defective, but the muscles responded normally to faradisation; in fact, the usual symptoms of hysterical paralysis were present.

The abdominal enlargement, always considerable, was sometimes very great; at times it was uniform, at times the prominence was greater in one locality than in another, notably on the right side below the liver. Along with this there was marked arching of the back in the lower dorsal region, so much so that the closed fist could be readily placed between the spine and the bed. No tumour, however, could be made out, and if her attention was completely diverted, while the abdomen was firmly compressed by the hand, the abdominal enlargement in great measure subsided, and on putting her fully under the influence of chloroform it entirely vanished.

On examination of the spine, two or three of the lower lumbar vertebræ were found to be very tender on pressure, although she made no complaint of pain in this locality previous to the examination. The whole of the left side of the body was completely anæsthetic as regards touch, temperature, and pain; there was also complete loss of general and special sensation on the corresponding side of the tongue; vision on the left side was also very defective, so much so that she was unable to read anything, and with this eye she was tested with six colours—red, green, yellow, blue, mauve, and black,—and was found to be completely colour-blind.

On Monday, Nov. 17th, metalloscopy was resorted to. At 10.15 A.M. a circular disc of lead, about three inches in diameter, was applied to the left forearm. At 10.22 there was a transference of the anæsthesia¹ from the left to the right upper extremity. On the abdomen the transference was less complete, while no change could be detected on the head, neck, or lower extremity. Vision was much improved in the left eye, and all colours were now recognised except yellow, which was called brown.² In about three minutes more, at 10.25 A.M., the anæsthesia was completely transferred to the whole of the right side of the body.³

On Nov. 21st, the patient's symptoms being the same as on admission, except that the vision of the left eye was much improved, she being able to read print of medium size by holding the book about an inch and a half from it, and being able to name all colours correctly, with the exception of yellow, which she still called brown, as after the first

¹ In all cases the sensation as to touch, temperature, and pain was tested by the fingers, the application of hot and cold sponges, and needles.

² During all the observations the patient was blindfolded, except, of course, when the eyes were being tested.

³ In all cases this is to be held to include the transference of general or special sensation, as regards the tongue as well.

observation, the disc of lead was again applied to the left forearm at 3.53 P.M. At 3.58 sensation began to return in the neighbourhood of the plate, while it disappeared at the corresponding part of the right forearm, and this went on spreading until 4.2½ P.M., when the patient began to weep, and then the transference of the anæsthesia to the right side was found to be complete. The left eye, too, was found to be normal, both as regards vision and the discrimination of colours. With the right eye, however, she could not read the same type as she did before the plate was applied. With it she could distinguish blue, but yellow she called brown, and the other colours she said she did not know.—4.13 P.M.: The same plate was applied to the right forearm. At 4.18 sensation had returned in the neighbourhood of the plate, and the needle punctures made in testing that part began to bleed. At 4.20 she began to weep, and then it was found that the transference of the anæsthesia from the right to the left side, which had been slowly advancing, was complete. The right eye was now normal in every respect, while with the left she could read medium type as before, but could distinguish no colour except blue.

Nov. 22nd.—3.15 P.M.: Patient in same state as on admission, except that she could distinguish colours with the left eye, with the exception of black and yellow, which she called brown. At 3.21 P.M. a circular disc of wood, about three inches in diameter, was applied to the left forearm. At 3.24 there was a transference of the anæsthesia to the right side, the sensation on the left side first appearing in the neighbourhood of the disc, from which it quickly spread, and the patient weeping, as on former occasions, when the transference took place. The left eye was now found to be perfect in every way, while with the right, although she could see print, she could not read it, and she could distinguish all colours, except yellow, which she called brown. At 3.34½ P.M. a disc of wood was applied to the right forearm, and at 3.37 the transference of the anæsthesia to the left side occurred exactly in the same way as in the last observation. These results were so extraordinary that they were repeated, and with exactly the same result.

24th.—Right side in every way normal. Left side complete anæsthesia as on admission, but with left eye can read print of medium size at a distance of an inch and a half, and can distinguish all colours except yellow, which she calls brown. 9.30 A.M.: Five sovereigns were applied to the left forearm and kept there for thirty-seven minutes. It was then found (what had been indistinctly observed a quarter of an hour earlier) that there was partial return of sensation as regards touch and pain, but not as regards temperature, to that side, and a corresponding loss of sensation (including, however, defective sense of temperature) on the right side. There was no change, however, in the condition of the eye.

26th.—Patient in the same state as at the end of last note. 9.9 A.M.: Lead plate applied to right forearm. At 9.13½ sensation became much more distinct in the neighbourhood of the plate; and at 9.15 the patient began to weep, and sensation was completely restored to the whole of the right side. With the right eye all the colours were distinguished except yellow, which was called brown. The left side of the body, including the tongue, was now completely anæsthetic, but by the left eye all colours were distinguished accurately.—9.19 A.M.: Lead plate applied to the right side of the face, and in two minutes all colours were distinguished accurately with the right eye, but with the left she called yellow brown, and was not sure about green.

Dec. 14th.—Since last note patient has been left entirely to herself. When tested to-day she was found to have dulled sensation on the right side, a needle stuck into the arm or leg only being felt as something touching her. On the left side she could only feel very heavy pressure. The tongue was in the same state as the body—that is, sensation was dulled on both sides. Her perception of colours was nearly perfect, although yellow she still called brown with the left eye. 4.37 P.M.: A tin-plate applied to the left forearm. At 5.7 P.M. there was a decided though not complete transference of anæsthesia to the right side, while the sensation was nearly though not quite restored on the left. With the right eye she now called yellow brown.

Jan. 4th, 1880.—Sensation dulled on both sides of the body, less so, however, on the right than on the left side; tongue in a similar condition. Can distinguish all colours equally well with both eyes.—11.15 A.M.: Lead plate applied to left arm. At 11.20 there was some improvement in the sensation on that side, and at 11.40 it was nearly complete,

while on the other side it was proportionately dulled. Tongue and eyes as before.

Feb. 13th.—It was intended to test the patient with solenoids and electro-magnets, in conjunction with Prof. McKendrick, but she was allowed an airing in the grounds, and took advantage of it to get away. A patient in the wards saw her making for a tram-car in the neighbourhood, and said that "She walked as well and as quickly as any woman could."

In the present state of uncertainty as to the nature and explanation of the phenomena observed in cases such as that just reported, it will probably be better to abstain from offering any speculations upon the subject, although it is to be hoped that by and by, when our experience of them becomes more extensive, a trustworthy opinion may be formed.

But it may be pointed out, in conclusion, that the foregoing differs from the case which I formerly put on record in these respects:—

1. That the convulsive seizures occupied a very subordinate place in the symptomatology of the disease.
2. That no tenderness in the ovarian region could be made out, although this may be due to the ovary having been protected from pressure by the prominent abdomen.
3. That the application of a disc of wood had a similar effect to that of a metallic disc, as regards the transference of the anæsthesia, &c., from one side of the body to the other.
4. That in no case did we succeed in making the whole body at once either æsthetic or anæsthetic.
5. That, in addition to the usual symptoms of hystero-epilepsy, there was well-marked spinal irritation, and morbid states long regarded as manifestations of the hysterical diathesis—namely, hysterical hemiplegia and phantom tumour of the abdomen.

Glasgow.

PASSAGE OF NEEDLE OF HYPODERMIC SYRINGE INTO BRONCHUS; EXPECTORATED DURING A PAROXYSM OF COUGHING THIRTEEN DAYS AFTERWARDS.

BY SYDNEY JONES, F.R.C.S.,
SURGEON TO ST. THOMAS'S HOSPITAL.

THE following case has recently come under my notice, and seems interesting enough to be put on record.

On June 21st a medical man, after using a hypodermic syringe, put the needle (size exactly indicated in figure below) between his lips. During an inspiration this was drawn into the larynx and passed down into the left bronchus. It caused occasional paroxysms of coughing,

which the patient described as not of a severe character; and the needle could be felt by him somewhat above and to the left of the left nipple. The patient went about his work as usual, and occasionally inverted himself in the hope that the foreign body might be expelled; but, finding that this did not occur, he consulted me on the 25th of June, four days afterwards. By means of the tripod I suspended him by the heels and subjected him to succussions in different directions, but did not succeed in evacuating the needle. I saw him the next day with Dr. Bristowe, who carefully examined his chest, but did not find any appreciable interference with the admission of air into the lung. We advised that the patient should be kept as quiet as possible, and were of opinion that any operative interference would be of doubtful benefit, and might do serious mischief. After about a week the patient began to feel less discomfort about his chest, "only occasionally being conscious of something preventing comfortable expansion." He had occasional fits of coughing, and on four or five occasions got rid of small pellets of bloody mucus. For a week his nights were somewhat restless; after that he slept better, but generally coughed and expectorated a little mucus on waking in the morning.

On Sunday, July 4th (the thirteenth day), the patient, whilst dressing himself about 10 A.M., had a fit of coughing more severe than usual, and presently got rid of the portion of needle-marked *a*. The process of oxidation had gone on rapidly, and the needle had separated into two portions at the spot marked *c* in the figure. A few hours later the other bit was coughed up. In both pieces the needle was much thinned. The white metal forming the tip of the needle was not at all acted on. Since getting rid of the needle there has been no cough or expectoration.

George-street, Hanover-square.

REPORT OF A CASE OF AORTIC ANEURISM TREATED BY GALVANO-PUNCTURE,

AT THE WESTMINSTER HOSPITAL, UNDER THE CARE OF
DR. STURGES AND DR. HUGHES BENNETT.

With a Commentary

By A. HUGHES BENNETT, M.D.,
ASSISTANT PHYSICIAN TO THE HOSPITAL.

Antecedent History.—James G—, aged forty-three, a labourer, had been a soldier for twenty-one years, and left the army in 1876. During this time he had been a perfectly healthy man, and had never suffered from any illness. Two years ago he began to experience pains in the chest, cough, and dyspnoea, which did not, however, prevent him following his usual occupation as an out-door labourer. In September, 1878, he observed two swellings on the upper part of the chest, each about the size of half a walnut; and the above symptoms so increased in severity that he was admitted into the Westminster Hospital on the following month. The existence of an aortic aneurism was then recognised, and he was kept under observation for five months, after which time his symptoms were greatly relieved. For the next sixteen weeks he remained at home, feeling so well that he subsequently resumed his work (road-making), which he continued to perform without difficulty till November, 1879, when he "caught a cold," and the former symptoms of cough, dyspnoea, and pain in the chest returned, suffering from which he was readmitted into the hospital.

Condition on admission.—The patient when admitted was a healthy-looking, powerfully built man, whose organs and functions were normal, except those of the chest. *On inspection:* A tumour of somewhat oval shape, five and a half inches in length and three inches in breadth, was seen lying obliquely at the upper part of the chest, its upper margin close to the inner third of the right clavicle and its articulation, and its lower border situated a little to the left of the sternum, about four inches above the ensiform cartilage. The surface of the tumour was irregular in form, and consisted of three rounded elevations, the upper or largest, the middle or smallest, and the lower, which was nearly as large as the first; and they measured vertically at right angles to the base of the growth respectively one, one-half, and three-quarters of an inch. The skin over the tumour was of normal colour, but, especially over the lower segment, was tense and glossy in appearance. No pulsation was anywhere visible. The veins over the manubrium sterni were considerably dilated. The whole of the right side of the chest, both back and front, was much larger than the left, the ribs being more expanded and the spine being slightly curved towards the left. The pupils were equal and normal. *On palpation:* The apex-beat of the heart could not be detected. The tumour was felt everywhere soft and pulsating, each impulse being synchronous with the heart's beat. There was also a distinct sensation of expansion in every part of the swelling. These signs were most marked in the lowest elevation, where the skin was tense and thin, so as to give the sensation as if the blood was flowing directly under the finger. No purring or thrill could be detected. Pulsation could also be felt for some distance to the right of the tumour, and gradually fading off towards the axilla. On the left side there was no impulse. No pulsation could be detected in either carotid artery, but it was present in the temporals. The pulse at

the left wrist was of good strength, at the right very feeble. The expansion of the chest on the left side on inspiration was well marked, while on the right it was in comparison imperfect. *On percussion:* The heart's dullness could not be measured, that organ evidently being covered by the left lung. Over the external tumour there was absolute dullness, and this extended to the right as far as the nipple-line, and also a little to the left of the swelling. The area of complete dullness extended vertically from the clavicle to the liver, and horizontally from the left border of the sternum to a line drawn obliquely through the nipple parallel to the direction of the tumour, measuring in breadth six inches and a half at its middle. Percussion over the right lung elicited great loss of resonance, but no actual dullness. The left lung was everywhere hyper-resonant. *On auscultation:* Over the heart, both sounds were distinctly heard to be perfectly normal at apex and base. These healthy sounds were propagated all over the right side of the chest, before and behind, but chiefly over the dull area. They were also distinctly audible on the left of the sternum, but faded off so as to be almost inaudible at the side and back. At a spot two inches below the middle of the right clavicle, a distinct but soft blowing murmur was heard synchronous with the first sound of the heart, and propagated for an inch or so on every side. Puerile breathing with slight sibilus were heard all over the left lung, which was otherwise normal. There was imperfect and feeble vesicular murmurs all over the right lung. The patient when in bed suffered in no way except from slight cough; he had no dyspnoea, difficulty of swallowing, or other symptoms of pressure.

It was decided to treat the case by galvano-puncture.

First operation, Feb. 17th, 1880.—Two insulated needles, each attached to different poles of the battery, were introduced into the sac at the lowest elevation, about an inch and a half apart, and two inches in depth. By the aid of a rheostat the full force of twenty cells of a Leclanché's battery was very gradually introduced into the circuit, so that the galvanometer indicated 25 millivebers. This current continued to pass through the blood in the aneurism for three-quarters of an hour. During this time the patient suffered from no inconvenience whatever. He declared he felt nothing but the introduction of the needles, the pain of which was trifling, and that while the current was passing he felt nothing. The withdrawal of the needle attached to the negative pole was followed by a rush of gas, and a few drops of dark-coloured blood. The positive needle was adherent to the tissues, was followed by no blood, and its uninsulated point was partially eroded away. A piece of dry lint was placed over the tumour and retained there with strapping. For some hours after the operation the patient suffered from pains flying about his back and shoulders, but after a hypodermic injection of morphia these disappeared. Next day the patient was well in every respect, there had been no bleeding, but there was slight puffiness of the skin in the neighbourhood of the punctures. Two days later the whole of the lower elevation was swollen, the skin was tender and covered with a red blush. No marked change was detected on the pulsation. Seven days after the operation the patient continued without any unfavourable symptoms.

Second operation, Feb. 25th.—Two needles, as before, were inserted into the sac of the upper segment of the tumour about an inch and a half apart, and two inches and a quarter in depth. The points of both needles came in contact with bone. A current from twenty cells, indicating on the disc of a galvanometer a force of 30 m. v., was passed through the aneurism for an hour. The patient suffered no pain or uneasiness during the operation. On withdrawing the needles there was no hæmorrhage. The positive needle was partially dissolved, and the negative was bright and unacted upon. Two days later the patient stated that he had suffered from no uneasiness except from flying pains about the back and shoulders. The upper segment of the tumour was swollen and puffy, and over it the skin was faintly red, but there was no tenderness on pressure. Four days afterwards the condition was the same, but this portion of the tumour felt firmer and less pulsatile than formerly.

Third operation, March 7th.—The needle attached to the positive pole was inserted at the under border of the lowest elevation, and that to the negative at the centre of the middle segment of the tumour. The details of the operation were as before, and the same strength of current was used for an hour, the needles being inserted two inches and

a half in depth. The patient, as before, suffered no pain. Two days afterwards the upper elevation was distinctly firmer and harder than at first. The impulse was as formerly, but the lateral expansion was markedly diminished; it felt hard, and no longer fluctuated; the lower elevation was still soft, but less so than before.

Fourth operation, March 11th.—The same steps were repeated, the negative needle being inserted into the most prominent part of the upper elevation of the tumour, and the positive into the centre of the middle segment. As before, a current from twenty cells was employed for an hour. On withdrawal, the positive needle was almost entirely dissolved. Eight days afterwards there had been no unfavourable symptoms. The upper segment of the tumour was now quite hard, and was smaller than formerly, and it had no trace of lateral expansion or pulsation, but there was an impulse all over its surface synchronous with the heart's beat. The lower segment was prominent, tense, and although firmer than formerly, still pulsated, and fluctuation and lateral expansion could be detected.

Fifth operation, March 19th.—Both needles were inserted into the lowest segment of the tumour, and a current from twenty cells, as before, passed through it for an hour. Six days later (the patient in the meantime having been quite well), a small abscess was found to exist in the site of the last puncture of the positive needle, and at the most prominent portion of the lower elevation of the tumour. It was then about the size of a sixpence, fluctuated, and was evidently superficial. Three days afterwards this abscess had increased, and was now about the size of a walnut. It was red, and the skin in the neighbourhood was inflamed. The patient was feverish and depressed. Five days later all the symptoms had increased. The abscess was then about the size of a hen's egg. It presented a dark, purple, fungating-looking appearance, and from the mass was exuding a little blood and yellow matter. It was no longer soft and fluctuating, but felt of a doughy consistency. The whole of the lower portion of the tumour was greatly swollen, red, and inflamed. This condition rapidly increased, and two days afterwards suddenly the sac gave way; there was a gush of blood, and the patient died almost instantaneously.

Post-mortem examination next day showed the whole body to be extremely anemic. The external tumour was smaller than during life. The upper and middle segments were prominent and firm, the lowest had entirely collapsed—at its inferior border there was a round, ragged rupture, about the size of a shilling. The trachea and bronchi were normal, except at the bifurcation of the former, where the mucous membrane was congested. The left lung was emphysematous throughout, otherwise healthy, and its anterior border completely covered the heart. In the cavity of the right pleura was about half a pint of clear fluid. The pleura itself was thickened, and adherent throughout to the walls of the chest and to the aneurism. The substance of the right lung was congested, oedematous, and partially collapsed. The pericardium contained about half a pint of clear serum. The heart was not weighed, owing to its being attached to the specimen, but was apparently of normal size, without hypertrophy or dilatation, and its substance was pale, but otherwise normal. The mitral and aortic valves were healthy, and there was no evidence of incompetency. Immediately above the aortic valves the aorta began gradually to dilate, and expanded so as to form a fusiform dilatation. This extended from the aortic valves to the lower portion of the descending arch. The widest portion was about the middle, where it measured in circumference eight inches. Its lining membrane was thickened, atheromatous, and here and there were embedded minute patches of calcareous matter. There was no obstruction to any of the large vessels, which arose from the summit of the dilated portion. Three inches above the aortic valves, in the centre of the anterior wall of the aorta, was a circular opening, the size of half-a-crown (diameter $1\frac{1}{2}$ in.), the upper border of which reached to within an inch of the innominate artery. This orifice led into a large sacular aneurism, which occupied the whole space between the aorta and the sternum, especially on the right side. Roughly speaking, this was about the size and shape of a flattened, moderately-sized cocoa-nut. On making an incision into this, its walls were found thick and firm. Its interior was filled with recent clots. On removing these it was found that the posterior aspect of the sac into which the orifice opened was white, smooth, and free from any clot formation; while the whole anterior portion—namely, that nearest the ster-

num, was completely covered with a dense, organised, fibrinous clot, about an inch in thickness. Embedded in this clot were three orifices. The upper one passed between the cartilages of the first and second ribs, at the right border of the sternum, to the posterior aspect of the upper segment of the external tumour, and admitted the forefinger. The middle orifice passed between the second and third ribs to the middle segment of the tumour. The lowest orifice, through the third and fourth ribs, communicated with the lowest elevation of the external tumour. In all these passages the finger could detect that the ribs, cartilages, and sternum in the neighbourhood were rough, bare, and denuded of periosteum, parts of the bone had been destroyed, and in the lower two the ribs were actually separated from the sternum. A vertical section made through the entire external tumour showed that the three elevations of the external tumour did not communicate with one another, but were each separated by a distinct wall of its own. The upper segment was entirely filled with a firm, dense, laminated, and organised clot of a pale red colour, occupying the whole space in the sac between the sternum and external wall. The laminae were arranged parallel to the walls of the sac, the centre from which they radiated being at the base of the clot. The middle elevation was also filled with firm organised clot, but not so dense or so distinctly laminated as in the upper segment. At the under border of the lowest elevation the opening where the rupture took place was seen. The interior was filled with recent clots and broken up old ones, and through this the finger could be passed without obstruction into the internal sac of the aneurism. At the seat of the rupture, under the skin and between this and the aneurism, was a sac about the size of a walnut. This was the cavity of the abscess, and it was through this that the blood escaped when the aneurism ruptured. At the outer edge of the upper segment there was a second cavity, about the size of an olive, containing about a drachm of pus. All the other organs of the body were healthy.

Commentary.—The treatment of aortic aneurism by galvano-puncture is comparatively so rarely adopted that each case claims special consideration. Is such a measure justifiable? In aortic aneurism, the only hope of recovery, or prolongation of life, is by the coagulation of blood in the sac, so that the tumour becomes converted into a solid mass of organised clot. Although this sometimes takes place spontaneously, in the vast majority of cases, owing to the situation of the aneurism, this does not ensue. On the contrary, the morbid process extends, and ultimately ends in rupture of the sac. We know that a galvanic current passed through blood rapidly coagulates it; and could such a procedure be accomplished within the aneurism, without danger to the patient, it is obvious that the natural process of cure would thus be assisted. This case, along with others, shows that, if properly performed with suitable instruments, the operation itself is not of necessity attended with any danger or even discomfort. That this patient died indirectly as a result of the fifth operation I look upon as an accident. The first four operations were attended by absolutely no unfavourable circumstances either local or general,—indicating that by itself the procedure is harmless. Unfortunately, immediately after the last puncture, erysipelas broke out in the ward, attacking several patients, one of whom died. To this, it is possible, may be attributed the local irritation and inflammation in the present case. On the appearance of the abscess it was suggested that the pus should be evacuated, but the surgeons thought it best not to interfere.

The construction of the needles is of great importance, and upon this the success of the operation greatly depends. Those hitherto employed seem to me to be clumsy, difficult of introduction, and imperfect in insulating power. Messrs. Coxeter and Son, of London, constructed those used in this case, which answered with satisfaction in every respect. They consist of a delicate steel needle with a flat spear-pointed head, and are insulated to within half an inch of their points by a delicate film of glass. These can be introduced into the sac with the greatest ease; the glass does not break or dissolve, and it insulates perfectly.

In this case, needles attached to both the positive and negative poles were inserted into the sac. Apart from the fact that a clot is formed into each, it is obvious that when both poles are directly in contact with the blood a much stronger current passes; in other words, there is less resistance than when the skin and tissues intervene, as occurs when one of the electrodes is placed externally. Hence a

given strength of current produces a much more powerful coagulating effect, without increased discomfort or danger to the patient.

In most of the cases hitherto recorded a small number of cells were used, and yet considerable uneasiness and pain were experienced. This was obviated in the present instance by the use of a rheostat introduced into the circuit, which enabled us to apply the full force of twenty cells without the patient feeling even any uncomfortable sensations. When the current from a large number of cells is suddenly applied to the body, not only is there a severe shock, but the burning pain afterwards is unbearable. It is, however, well known that galvanism is a nerve-anæsthetic; hence a feeble current dulls the sensation for a subsequently stronger one, and this in turn for one more powerful, and so on. Thus, by slowly and insidiously increasing the strength without producing any shock, which the rheostat can accomplish, a current so powerful can be passed through the tissues without pain, which if suddenly applied would be intolerable.

That a powerful current in this case actually passed through the blood was demonstrated, not only by the positive needle being dissolved, but by a galvanometer, which was always employed. By this it was ascertained that in the circuit, of which the aneurism formed a part, there passed a current measuring from twenty to thirty millivolts.

A somewhat pertinent question was asked at the post-mortem examination, Are the organised clots the result of the galvanism, or did they not exist before the operations were performed? From the appearance of the formations themselves, it is difficult to settle this question. The fact of their being dense, organised, and laminated, suggests their being of ancient date, and whether it is impossible for such to be produced in six weeks after electrolysis, is a point I cannot answer. The lamination is in no way opposed to the clot being produced by electricity, as Dr. McCall Anderson and others describe and figure precisely similar conditions resulting from galvano-puncture. On the other hand, when the patient was admitted, the tumour was carefully examined by many competent physicians and surgeons, who all agreed that it was soft, fluctuating, pulsating, and with lateral expansion; and before death the same regions were found by the same observers to be dense, hard, resistant, and non-fluctuating. From these facts it may be assumed that the subsequent consolidation was due to the action of the electricity on the blood.

In conclusion it may be stated that, with our improved knowledge of electricity, and the more perfect instruments for its application we now possess, a great field is opened out for the treatment of aneurisms in general, and those of the aorta in particular. Hitherto the results of this procedure in the latter have not been successful as regards saving life, but this may be explained on the ground that it has only been employed in hopeless cases, and in those, after which every other treatment having failed, it has been adopted as a last resource. In the present case, had the operation been performed when the patient first came under observation a year ago, judging from the post-mortem appearances, the prospect of a cure or prolonged alleviation, appears not only possible but probable. As it was, this treatment was carried out because it was judged the patient if left to nature could not live many weeks. Considering that galvano-puncture if properly conducted appears to be practically harmless, there need be no hesitation in resorting to its application in any case of aortic aneurism, which can be easily diagnosed to be sacular in character, and which can be reached without difficulty.

REPORT ON ONE HUNDRED CASES OF EAR DISEASE.

By E. CRESSWELL BABER, M.B. LOND.,

SURGEON TO THE BRIGHTON AND SUSSEX THROAT AND EAR DISPENSARY.

FROM July, 1878, to December, 1879, one hundred different cases of ear disease came under my care at the above institution, of which notes, more or less complete, have been kept. They include the following forms of ear affection: One case of abscess of the auricle; four cases of diffuse external otitis (unilateral); eighteen of impacted cerumen

or epidermis (nine unilateral and nine bilateral); one case of exostoses of the external auditory meatus (unilateral); two cases of Eustachian obstruction; four of acute catarrh of the middle ear (two unilateral and two bilateral); and one case of otitis media serosa (unilateral). There were also twenty-seven cases of otitis media purulenta chronica (thirteen unilateral and fourteen bilateral), nine of these being complicated with polypus (the growths being unilateral in eight cases and bilateral in one instance). One case of chronic purulent inflammation of the middle ear was complicated with mastoid periostitis. Results of suppurative processes in the tympanum were found in fourteen cases (five unilateral and nine bilateral); and there was one case of necrosis of the temporal bone, and one of deaf-mutism. Of the remaining forty-seven cases, the great majority were classed under the head of "otitis media catarrhalis chronica," or would be better termed "otitis media non-suppurativa chronica," seeing that they included also the sclerotic or dry forms of middle-ear disease. In a considerable proportion of these cases (as well as of those above classified as "results of suppurative processes") there was evidence of nerve-impairment to a greater or less extent. Whether this was secondary to the tympanic mischief or constituted the chief affection could not always be accurately ascertained, partly from want of time, and partly from irregularity of the patients' attendance—circumstances which unfortunately often render records of out-patient practice incomplete. Apart from this, however, as Lucae has not long since pointed out,¹ the distinction between nerve-deafness and chronic non-suppurative inflammation of the middle ear (in the less well-marked forms) constitutes one of the weakest points in aural diagnosis. In at least three cases nerve-impairment was well marked, one of them being a case of congenital syphilis, which is still under treatment (March, 1880). More than one of the above diseases of course often occurred in the same patient.

Impaction of cerumen or epidermis.—In four of these cases (two unilateral and two bilateral) the impaction of wax came on after bathing or diving. The symptoms being deafness with tinnitus, continuous or pulsating, and of "hissing," "rushing," or "singing" character. This, as far as my experience extends (both in dispensary and private practice) is the most common form of ear-affection, attributed by the patients to bathing. Removal of the wax almost invariably relieves all the symptoms. Under the same heading is included the following case of impaction of epidermis, associated with chronic purulent inflammation of the tympanum and nerve-impairment, which forms a well-marked instance of the disease described by Wreden of St. Petersburg as *keratosis obturans*.

Case of keratosis obturans.—M. J.—, aged forty-five, chemist's assistant, applied on August 15th, 1879, with the following history:—Has had dulness in the left ear since he was a boy, which has been worse the last three months. No noise, pain, or discharge. Never had any fever. On admission, with the right ear watch² was heard at $\frac{1}{2}$ in. distance; left not at all. Tuning-fork on teeth heard loudest on left side, but not heard on forehead or on bridge of nose. A large quantity of epidermis in long-shaped pieces removed from the left meatus by syringing, but as some still remained drops of bicarbonate of soda dissolved in glycerine and water were ordered to be instilled into the meatus.

Aug. 18th.—A quantity more of white folded and corrugated epidermis was removed from the left meatus, a large portion of it having to be carefully extracted with forceps, as it was very adherent to the walls of the canal. Afterwards the meatus appeared dilated and of pearly and shining aspect. Hearing for watch not improved on the left ear.

29th.—There had been some discharge from the left ear. Watch heard with right ear at $\frac{1}{2}$ in.; left slightly on pressure on auricle and mastoid. More large epidermic scales removed from left meatus by forceps and scoop, after removal of some purulent discharge by syringing. Left membrana tympani then presented a white surface with scales on it and granulations in the posterior superior segment. On Politzerising perforation sound in left ear. Afterwards hearing about the same.

¹ Archiv f. Ohrenheilkunde, xiv. 2, p. 125.

² The watch mentioned throughout this paper is heard audible normally at about ten feet.

The patient was seen a few times after this, and the granulations touched once or twice with a solution of nitrate of silver (a drachm to the ounce). They presented the peculiarity of bleeding, not only when touched with the tuft of cotton-wool in applying the caustic, but even on mere syringing. When last seen, the watch was not heard at all at the left ear.

Remarks.—Whether in this case the perforation was the result of the pressure of the accumulated epidermis, or whether the tendency to the excessive formation of epidermis was superadded to a case of chronic suppuration in the tympanum, must, I think, remain doubtful. Although, owing to the nerve-impairment, the removal of the epidermic accumulation did not effect any improvement in the hearing power, it was undoubtedly of benefit in preventing any accumulation of pus behind the epidermic masses. (The specimen removed from this case was exhibited, and an account of the case given before the Sussex and Brighton Medico-Chirurgical Society in November last.)

The case of *exostosis of the auditory meatus* occurred in the ear of a man aged thirty-one, suffering from chronic non-suppurative inflammation of the tympanum, probably of gouty origin. They were two in number, and situate on the anterior and posterior walls of the meatus respectively, but as they did not encroach greatly on the lumen of the canal, they demanded no special treatment. The four cases of *acute catarrh of the tympanum*, which all occurred in adults, did well without paracentesis. The operation did not appear indicated, probably because the cases were not seen early enough. In only one case was a minute perforation observed whilst the patient was under treatment, and in this instance it healed readily.

The following case is interesting on account of the obstinate recurrence of the effusion into the tympanic cavity, associated with repeated occlusion of the Eustachian tube:—

Otitis media serosa; paracentesis; reaccumulation of fluid; treatment without paracentesis.—Mary S—, aged forty-eight, single, applied on March 31st, 1879, with the following history. Left ear has been deaf for years from discharge. Right ear has been deaf for one year, she believes owing to cold from sleeping near a damp wall. She thinks it gathers sometimes, and discharges down her throat. Throat feels swollen and aches at times. Last summer she had violent pain in the right ear, and went to the Throat Hospital in Golden-square, where she says the ear was punctured. *Present state:* Watch heard only on contact with right temple. Right membrana tympani yellowish. After Politzer-inflation watch was heard right ear at half an inch, also on contact with right mastoid and temple. The posterior segment of the right membrana tympani is then seen bulging outwards, with yellow fluid shining through.

April 2nd.—Right ear: watch heard almost on contact, and slightly on contact with mastoid. Membrana tympani has a yellow tint, and appears somewhat streaky. Politzerising produces no improvement in the hearing for watch, although it causes the membrane to bulge with yellow fluid, showing through, as yesterday. On the anterior segment of the membrane is a thin layer of wax or hardened secretion. A puncture about two millimetres long is then made vertically downwards in the posterior segment, which allows some serous fluid to escape. On repeated Politzerising, producing, of course, a perforation sound, a considerable quantity of clear yellow fluid runs out into the concha. Parts cleansed with dry wool. Immediately afterwards watch is heard with right ear at one inch and a half.

3rd.—With right ear watch heard at one inch and three-quarters, and plainly on right mastoid. Point of puncture indicated by a small blood spot. The posterior segment of the membrana tympani has lost its yellow colour. On Politzerising air enters the right tympanum freely, but I cannot be sure of perforation sound, and no change in the puncture is produced, neither does any discharge escape.

4th.—There has been no discharge from the ear. The hearing has improved to 3 in. for watch. No perforation sound on Politzerising; but inflation diminishes the hearing to 1½ in.

7th.—After removal of a thin layer of yellow discharge from the surface of the membrana tympani, there appears to be yellow discharge shining through its anterior inferior segment, but not through the posterior. Politzerising improves the hearing from ½ in. to 1½ in.

The patient was then seen about thrice weekly until

August 1st. She was treated locally by Politzer-inflation, vapours of compound tincture of benzoin, firwood-oil, creasote, &c.; internally, tonics and chloride of ammonium. On three occasions (June 6th, July 2nd, August 1st) the catheter had to be employed, as air would not pass on Politzerising. The tube did not always yield on catheterising, but subsequent Politzerising was always successful, usually with considerable improvement to the hearing (from which it may perhaps be concluded that the obstruction in the tube was at or near the faucial orifice). The hearing for the watch, though it varied very much, improved decidedly on the whole. After each inflation the hearing was usually found improved, but on one or two occasions it was temporarily diminished, perhaps owing to a rushing noise in the ear produced by the inflation. Not only did the lining membrane of the tympanum participate in the inflammatory condition, but also the outer surface of the membrana tympani; for on July 14th the membrane appeared opaque and uneven, with the hammer very indistinct, only the small process being visible. A short time after, a regular membrane of dry yellow discharge was removed with the scoop and forceps from the surface of the membrana tympani. When the patient was discharged, on August 1st, the hearing distance was—Right ear, watch 5 in.; after inflation 7½ in.

On Aug. 18th she was readmitted, yellow fluid again showing through the membrana tympani, the hearing having gone back to 1 inch. This time she was only treated by inflation and vapours, and was discharged on Sept. 15th with hearing distance:—Right ear, watch, 4½ in.; improved by Politzerising to 8 in.

Quite recently—Feb. 27th, 1880—this patient has returned with the hearing for the watch reduced to “contact,” and the fluid reaccumulated. I proposed to puncture the membrane again, and if necessary pass a stream of fluid through the ear; but the hearing has improved so much on simple inflation, with the head held so that the Eustachian tube is in the most dependent position in order to allow the fluid to run out (as recommended by Politzer),³ that I have not done so yet.⁴

The following case is one of interest:—

Tinnitus, audible objectively.—E. D—, aged twenty-three, unmarried, laundress, applied on Oct. 14th, 1878, giving the following history: For three years on and off she has had a clicking noise in the left ear, and has noticed deafness in that ear during the same period. No pain or discharge. Has always enjoyed good health. The noise, which is audible to other persons, is louder than it used to be, and her neighbour, who accompanies her, thinks it comes on especially when she is excited. She sometimes has a buzzing noise in the right ear. (It appeared subsequently that about a year previously there had been discharge from the ears, chiefly the right one.) On examination the watch was heard with left ear at 3½ in. Left membrana tympani presents a large circular perforation, rather below its centre, into which the handle of the malleus projects. Perforation quite dry, and the exposed mucous membrane of tympanum appears of yellowish colour. Both in front and behind the malleus the membrana tympani presents a hard white surface, probably chalky deposits. Perforation-sound on Valsalvan inflation. There is no noise at present.

Oct. 18th.—Since last seen she has had the noise twice, lasting twenty minutes. With right ear watch heard at 15 inches. Right membrana tympani presents a considerable sized perforation at the lower part, and also two chalky deposits on the membrane. No discharge.

21st.—No noise till yesterday, when it lasted ten minutes. Left membrana tympani appears the same. On making her move the upper jaw up and down, a fine clicking sound is heard which takes place irregularly, but soon ceases after the movement of the jaw is stopped. On careful inspection of left membrana tympani, during the noise no movement of the malleus can be detected, nor any bubbling through the perforation. The clicking sound is brought on again by Politzerising, but soon ceases. She says it is often much louder than this. The noise heard to day resembles very much that produced by snapping the nails together. Throat, nothing abnormal.

Nov. 1st.—On swallowing, a similar click is heard through otoscope placed in left ear, only somewhat fainter than when it occurs independently of swallowing. When the otoscope

³ See his Handbuch, vol. i., p. 325.

⁴ Subsequent experience confirms the great tendency to relapse in this case, and inflation only appears to improve the hearing for a time (August).

is placed in the right ear, a very faint click is heard on deglutition, apparently similar in character to that heard on the left side. The noise is heard to-day a few times independently of deglutition, but is not loud. After the clicking ceases she has a buzzing noise in the ear.

I was naturally anxious to hear the noise in this case during one of the attacks, when it was occurring loudly, especially with a view to examining the throat during its occurrence, but in spite of repeated injunctions to the patient (who lived at some distance) to present herself if possible when the noise was taking place loudly, I could not get an opportunity of hearing it.

I saw this patient again in February, 1879. There was no change in the membrana tympani, and the clicking noise still continued at intervals. My attempts to see the patient during an attack were again unsuccessful. On one occasion she reported that after retching during a bilious attack, the noise came on very loud, and lasted for half an hour. It should be mentioned that although the buzzing noise occurred in both ears, the objective clicking sound was, according to the patient, confined to the *left ear*.

Remarks.—Although the observation of this case is unavoidably incomplete, I think (from the similarity of the noise to that produced during swallowing, and from the absence of movement in the malleus) there can be little doubt that the clicking noise was produced by a separation of the moist walls of the faucial orifice of the tube as occurs during deglutition. This view agrees with that of Burnett, who describes these cases at length in his work on the ear. Quite recently also he has reported⁵ the case of a gentleman who was able to produce a noise of this description at will. On the other hand, however, Dr. Bremer of Copenhagen has lately⁶ described the case of a boy who could voluntarily produce an objective noise apparently of similar character, which continued *unchanged in intensity and character* whilst a bougie was passed through the catheter to the isthmus of the Eustachian tube. Although no movements in the membrana tympani could be observed Dr. Bremer attributes the noise in this case to the action of the intrinsic muscles of the ear, especially the tensor tympani.

Arguing from the fact that complete cessation of the noise occurred after spontaneous perforation of the membrana tympani in a case under his care, Burnett⁷ recommends artificial perforation in these cases if relief from the symptoms should be urgently required. My case appears to throw doubt on the success of this plan of treatment, for in this patient the membrane, as mentioned, was already perforated. This affection appears to be more common in men than in women, for, according to Burnett (who writes in 1877)⁸ "of all those in whom such an objective aural noise, either voluntary or involuntary, has been observed only three were females." The points of interest in this case are, therefore, that the noise was involuntary, that it occurred in the female sex and in connexion with an ear of which the membrana tympani was perforated.

The term "*chronic catarrhal or non-purulent inflammation of the middle ear*" includes, I cannot but think, a number of cases which are really of very different character. For the history, and also the prognosis, in some of these cases are so different that but for the name they appear to have little in common. The subject, however, is too large a one to be discussed in this paper. There are several other points of interest in different cases in this series; indeed it may be said that a large proportion of ear-cases, if only carefully studied and treated, present features of interest. An account of these, however, must be postponed until the special subjects to which they refer are dealt with.

Brighton.

APOTHECARIES' HALL OF IRELAND.—On the 2nd inst. the following were elected office-bearers for the ensuing year:—Governor, Edward H. Bolland; Deputy Governor, Thomas Collins. Court of Directors and Examiners: John Evans, Arthur Harvey, Charles Holmes, Charles H. Leet, Charles J. Moore, Robert Montgomery, Henry P. Nolan, Jerome O'Flaherty, Edward J. O'Neill, George B. Owens, John Ryan, James Shaw, George Wyse. Examiners in Arts: H. Colpoys Tweedy, Arthur Wilson. Representative on the General Medical Council: Charles H. Leet.

ON THE ANTI-MALARIAL ACTION OF THE CHINCHONA COMPOUNDS.

By T. J. MACLAGAN, M.D.

(Continued from p. 187.)

BUT though there are many analogies between continued and malarial fevers, there are also great and important differences. These, equally with the analogies, demand attention. They are as follows:—

1. There is ample evidence that the poisons of the continued fevers are reproduced in and given off from the system in large quantity during the course of the maladies to which they give rise. There is not such evidence in the case of malarial fevers.

2. The continued fevers are communicable from the sick to the healthy. Malarial fevers are not.

3. The continued fevers have a continuous regular course, and a definite period of duration. The course of malarial fever is intermittent and irregular, and its period of duration indefinite.

4. One attack of the continued fevers confers, as a rule, immunity from a second. There is no such immunity in malarial fever.

Let us consider each of these points.

1. *Contagia are produced in and given off from the system. Malarial poisons are not.*—The evidence of the reproduction of the poisons of the continued fevers is their elimination in increased quantity and in an active form. And the evidence is sufficient. A poison cannot be received into the system in small quantity, and be given off from it in large, without having been reproduced there. But though increased elimination is a proof of reproduction, its absence is not a proof to the contrary. An organised poison might be reproduced in, and exercise its action on, the system, without being eliminated in an active form. Its life history might be completed in one cycle of growth within the system, and itself come to an end in the course of the morbid action which it set going. Or it might be destroyed and disintegrated in the system and thrown off by the eliminating organs. In either case it would pass from the system in a form different from that in which it entered it. It is certain that in malarial fever the poison is introduced from without. It is probable that this poison is an organism. If it be so, its action is likely to bear a relation to its organic growth.

The phenomena of these fevers are, indeed, such as can scarcely be explained on any other view. A short residence—even one night—in a malarial district may give rise to a fever of some weeks' duration. If during one night the patient inhales enough poison to cause so prolonged an attack of fever, if the whole of the poison requisite to the production of such an illness exist in the system at the commencement of the attack, he surely should be killed right off by it. Again, if the dose taken suffice to cause the fever, why does it not go on acting? Why are there intermissions and remissions? Why is the patient one day in a raging fever, and the next day free from it? And why, in the absence of treatment, does this alternation of pyrexia and apyrexia go on indefinitely?

If the whole of the poison necessary to the production of all the phenomena of the malarial fevers existed in the system at the commencement of the illness, they would lose their intermittent and remittent character, the full effects of the poison would be produced at once, and their phenomena would be concentrated into one violent attack of fever which could scarcely be recovered from.

It is impossible to explain the phenomena of the malarial fevers on the supposition that the whole of the poison necessary to the production and full development of each exists in the system at the time of its onset. Their varying course, their often increasing severity, their prolonged duration, and their small mortality, can be accounted for only on the view that their poisons are reproduced and destroyed during the course of the maladies to which they give rise—that that which produces the symptoms of to-day has to-morrow ceased to be active, but has given rise to an offspring which keeps up the action which its parent set agoing, and in its turn hands down to its offspring the same morbid properties which itself received.

Such reproduction is peculiar to organised structures. That the poisons of malarial fevers are somehow destroyed in the system there can be no reasonable doubt. They enter it from without; they are almost certainly reproduced therein, and they are not eliminated in an active form. They must, therefore, be destroyed and disintegrated. The only alternative view is that they remain permanently in the system, and that is an untenable position.

It seems to me that we must accept the view that malarial poisons are destroyed, probably in some of the eliminating organs, and that the products of their destruction are eliminated with the ordinary excreta. The presence of these products in the system may partly explain the unusually copious urinary deposits which are noted in connexion with intermittent and remittent fevers.

The fact that malarial poisons are not eliminated in an active form does not prove that they are not reproduced.

2. *Malarial fevers are not communicable from the sick to the healthy.*—Communication of a disease means the passage of its poison from the bodies of the sick to those of the healthy. It therefore presupposes the elimination of that poison in an active state. Malarial fevers are not communicable because their poisons are not so eliminated. Non-communicability is at once the proof and the necessary consequence of non-elimination in an active state.

3. *Malarial fevers have an intermitting, indefinite course, and an irregular period of duration.*—The poisons of the continued fevers and of malarial fevers, if organisms, are also parasites. As such they require for their development something more than the bare materials requisite to organic growth—something which they find in their nidus, and which is as necessary to their reproduction as are nitrogen and water to their organic growth. The materials requisite to organic growth exist all over the body, and are practically unlimited. The special material which the poisons find in their nidus (and which for convenience sake we call the second factor) is not so. It exists only in the nidus in definite and limited quantity, and may therefore be readily exhausted. In typhoid fever, for instance, it is limited to the intestinal glands; in small-pox to the skin. So long as any of this second factor exists, the poison continues to be propagated, and the febrile symptoms are kept up. When it is exhausted, the system no longer possesses the necessary nidus—no longer presents to the poison the conditions requisite to its continued action—its propagation ceases, and the fever comes to an end.

The quantity of the second factor is not the same in all persons. It has an average, however, and the period requisite for using up this average represents the mean duration of the malady. If the quantity be large, the contagium finds a rich field for its propagation and development, and the resulting attack is prolonged and severe; if small, the field is a poor one and the resulting attack is short and mild. The course of the continued fevers is continuous and regular, because the quantity of the second factor in the nidus does not fluctuate during the course of these fevers; and because, therefore, the contagium goes on being reproduced steadily, continuously, and without break or intermission, until the nidus is exhausted.

Their period of duration is definite, because the second factors necessary to the propagation of their poisons exist in limited and definite quantity, are exhausted in a given time, and when exhausted are reproduced tardily or not at all.

In typhoid fever, for instance, the second factor necessary to the propagation of the poison of that disease has its seat in the intestinal glands. In the absence of these glands (as in infancy, in old age, and after their destruction during an attack of typhoid), the typhoid poison has no action on the system; it is as impotent for evil as is the poison of small-pox to one who has already suffered from that disease. At the commencement of an attack of typhoid fever these glands contain a certain quantity of the second factor. This quantity must be both definite and limited, because the size of the glands is so. It is because its quantity is definite, and not liable to vary during the course of the disease, that the fever is continuous. It is because it is limited, and is not apt to be reproduced, that the fever has a fixed period of duration.

If there existed a parasitic organism whose second factor, after having been exhausted, was readily and quickly reproduced before the first factor, the organism was all eliminated from the system, the fever resulting from the propagation and growth of this organism would consist, not of one continued attack, but of alternations of pyrexia and apyrexia;

and as the exhaustion and reproduction of the second factor might go on indefinitely, so also might these alternations. In this way there would be developed a disease having all the characteristics of intermittent fever.

If the second factor were still more rapidly reproduced, it might never be thoroughly exhausted. Its quantity might only be considerably reduced, and continue to rise and fall, for some time without ever being thoroughly used up. In this way there would be produced a disease having all the characteristics of remittent fever.

If the second factor, instead of being localised, as it is in the eruptive fevers, existed in the blood, such rapid reproduction would be very likely to take place; for the blood is an ever-changing fluid containing nothing but what, when removed, is likely to be replaced.

That the second factor may exist in the blood, and may be so quickly reproduced as to give rise to alternations of pyrexia and apyrexia, is evidenced by what we see in relapsing fever. This is the only one of the continued fevers in which an organism has been detected in the blood. It is also the only one in which the course of the fever is not continuous, and in which there is no characteristic local lesion. With reference to the spirilla which is found in the blood, it has been proved that it exists during the pyrexia, and is absent during the apyrexia; and there can be no reasonable doubt that the spirilla is the poison whose propagation causes the disease.¹

From what we find occurs in relapsing fever, we know that the period of pyrexia corresponds to the period of abundant propagation of the organism—the period of apyrexia to its absence. From what we believe regarding the nature of the poisons of malarial fevers, from a consideration of the phenomena to which they give rise, and from a comparative study of what is observed in the somewhat analogous case of relapsing fever, we regard it as in the highest degree probable, first, that the poisons of intermittent and remittent fevers find the second factors necessary to their propagation in the blood; second, that this second factor is at no time very abundant; third, that it is, therefore, quickly used up during the active propagation of the poison; and fourth, that when used up it is quickly reproduced. The rapid using up and speedy reproduction of the second factor have much to do with the production, not only of the characteristic intermissions and remissions of these fevers, but also with their equally characteristic indefinite period of duration. Their course is intermitting and irregular, because the quantity of the second factor essential to the reproduction and action of their poisons fluctuates and varies during the course of this action, and because therefore the quantity of poison reproduced varies from day to day. Their period of duration is indefinite, because the tendency to the speedy reproduction of the second factor is not limited to a definite period of time.

In the malarial fevers, as in relapsing fever, a time comes when the renewal of the second factor is so retarded that the poison is all got rid of before that event takes place. The advent of this time marks the onset of convalescence.

4. *One attack of malarial fever confers no immunity from a second.*—The insusceptibility to the action of the poisons of the eruptive fevers enjoyed by those who have once suffered from them constitutes one of their most striking characteristics. As the decline of the fever is due to the exhaustion of the second factor, so immunity from a second attack is due to its non-reproduction. If, after having been exhausted, the second factor be not reproduced, the system no longer presents the conditions requisite to the propagation of the contagium, and it does not act. That such is the explanation of the immunity from second attacks enjoyed by those who have once suffered from these diseases is evidenced by the fact that, as a rule, no amount of exposure to their poisons, not even their direct introduction into the system, serves to produce a second seizure.

It is to be noted that this immunity is peculiar to the eruptive fevers, that is, to those forms of continued fever in which the second factor is localised in some particular organ; and that relapsing fever, the only form of continued fever in which the second factor is not thus localised, is also the only one in which one attack confers no immunity from a

¹ The opinion is indeed held by some that the fever is primary and the spirilla secondary—that the former induces a condition of the blood which favours the development of the latter. But if that were the case the spirilla should equally be found in typhus, typhoid, and other fevers in which the febrile disturbance is as marked as in relapsing fever. But it is found in no fever except relapsing.

second. In relapsing fever the second factor exists in the blood. Now it is evident that a lasting impression may be more readily made on a formed and solid organ than on a constantly-changing fluid like the blood. An organism which finds its second factor in the former is, therefore, more likely to produce a permanent effect than one which finds it in the latter. Moreover, it is to be observed that some of the tissues which are the seat of the local lesions of the eruptive fevers undergo permanent change in the ordinary course of nature. I would specially instance the tonsils, which are affected by scarlatina, and the intestinal glands, which are involved in typhoid fever; both of which dwindle away and ultimately disappear as years advance.

In intermittent and remittent fevers the second factor is readily reproduced, because it exists in the blood.

The same tendency to the reproduction of their second factors, which serves to account for the varying course and indefinite duration of these maladies, serves also to explain their tendency to recur again and again in the same individual. The second factor is reproduced, and with its reproduction there is a renewed susceptibility to the action of the first.

It is generally said that one attack of malarial fever produces a greater susceptibility to its subsequent recurrence. The truth is that the constitutional peculiarity which led to the first, leads equally to subsequent attacks, and the later as well as the earlier attacks are merely the evidence of the existence of this peculiarity.

(To be concluded.)

A Mirror OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

WESTMINSTER HOSPITAL.

PLYLEPHLEBITIS; RIGORS SIMULATING AGUE.

(Under the care of Dr. O. STURGES.)

FOR the following notes we are indebted to Mr. W. Gristock, M.B. Lond., medical registrar.

H. M—, aged fifty-eight, was admitted April 22nd, 1880. She stated that she had lived till twelve years old in Essex, in a marshy district, and had had ague (tertian) several times; never since childhood. She had always been strong and healthy, but twenty years ago she had scarlet fever, from which she quite recovered, and twelve years ago she had rheumatic fever, and had not been quite so strong since. She did not complain of pain, palpitation, &c. Father of patient died of "consumption," aged forty-two. Her mother died, aged fifty-one, cause unknown to patient. There was nothing particularly noteworthy in the family history. The present illness began three weeks before admission, with "fever" and "aching in limbs," which kept her in bed. About ten or twelve days later she began to have ague-like attacks, which recurred daily, sometimes three times a day.

On admission, she was sallow, but not jaundiced, and was fairly well nourished. She had no pain or tenderness anywhere. The tongue was dryish, with white fur. The attacks occurred daily in the afternoon, and also in the morning on April 23rd, 24th, and 27th. These attacks at first closely resembled ague, and were mistaken for it. There was a regular sequence of "cold stage," lasting fifteen to twenty-five minutes; "hot stage," lasting from half an hour to three hours; and "sweating stage," of variable duration. In the attacks the temperature rapidly rose to about 105° Fahr. (the highest temperature was 105° 6' on April 24th), and then rapidly sank to subnormal. There were, however, no long intermissions of fever. Quinine was given in five-grain doses on April 23rd; in ten-grain doses on the 24th and 25th. Five grains three times a day were ordered on the 28th, and also two ounces of brandy in twenty-four hours. The quinine had an obvious effect in arresting the rigors, but did not seem otherwise to affect the

course of the disease. The last rigor occurred on May 2nd, and after then the temperature gradually fell, though there were still great diurnal variations. After May 6th it was persistently subnormal—below 95° on the 10th. There was rapid wasting, and for several days before death the patient was very collapsed, and took nourishment with great difficulty. She sank very gradually, and died on May 12th. The pulse throughout was rapid, but variable and weak. The tongue was dry, extremely so towards the end, and covered with thick brown scales. The bowels were regular throughout, rather loose. Urine deposited large quantities of lithates, but never any albumen. On April 28th the liver-dulness was noticed to be increased, and the margin of the liver was felt below the ribs. The splenic dulness also was a good deal increased. The patient's prostrate condition prevented careful examination.

Necropsy thirty-three hours after death.—The body was very emaciated. The heart weighed 12 oz.; all the valves were thickened, and the aortic valves were not quite competent; there was commencing atheroma at the root of the aorta, but no ulcerative processes. The lungs were somewhat emphysematous. The spleen weighed 13 oz., was soft; capsule normal. The kidneys weighed 4 oz. each, and were fatty; cortex diminished; capsule adherent; surface smooth. The uterus contained two small fibroids in the fundus, one containing pieces of true osseous tissue. An old fibrous membrane was adherent to right cornu. The liver weighed 54 oz.; the capsule in various places was easily detached; general colour dark red; the upper surface of the right lobe bulged up against the diaphragm over an area of about two inches square. Over this area the liver and contiguous surface of the diaphragm were covered with purulent lymph; beneath this area, and extending into hepatic substance for an inch and a half in depth, was a portion of much lighter colour than the rest of the liver, and separated from it by a distinct capsule. The included part did not apparently contain pus. Most of the large portal veins were quite filled with pus, which reached, in many instances, into the finer branches, so that a section of the liver gave the appearance of a branch with leaves on it. The course of the pus was traced from the portal vein to the pancreatic and duodenal vein, which appeared dilated, and contained a clot requiring some force to remove it from the walls of the vessel. For about two inches the intima of the vein was swollen, thickened, and of a dark colour, and could be easily stripped off, leaving a rough surface. The tributaries of the vein were normal, and did not contain clots. Two or three glands in the adjacent mesentery were enlarged and contained pus. The stomach and peritoneum, except in the parts above-mentioned, were healthy. The duodenal mucous membrane was congested. There was no ulceration anywhere in the intestine.

PROGRESSIVE WASTING; RIGORS; CASEATION OF SPLEEN.

(Under the care of Dr. STURGES.)

W. J. E—, aged forty-nine, was admitted on March 31st, 1880. He stated that he had had rheumatic fever thirty-six years before, but quite recovered. He had had no other known illness. He was well till January, 1879, when he felt pain in the left hypochondrium, preventing him lying on his back on the left side. His bowels also began to be confined, requiring continual purgatives. The pain increased till May, 1879, when he had a severe attack of vomiting, bringing up blood and "stuff like white of egg." In the following June he felt "something give way inside," and almost immediately passed a large quantity of blood and pus from the bowel. He was never after free from more or less pain in the abdomen and loins. The patient's manner was confused and rambling, rendering it very difficult to get details.

On admission he complained of pain in the left hypochondrium, epigastrium, and both lumbar regions. He had also cough, accompanied with much expectoration of thick mucus, was 'ng, and dysuria. There was no albumen in the urine. The bowels were confined, and the tongue was swollen and furred. On April 15th medium-sized crepitations were heard over bases of both lungs, and these continued to be audible till death, especially on the left side. The patient had three distinct rigors (on April 22nd and 23rd and May 2nd respectively), each accompanied with high temperature, and followed by profuse sweating. There were no other rigors. In the beginning of May he became drowsy and listless, but could be easily roused. His mind became more and more confused, and later he had delusions and

occasional quiet delirium. The temperature till a day or two before death was high and variable (highest temperature 104.2° on April 19th and 22nd). For a day or two before death the temperature was lower (98.8°—100° F.) The pulse varied from 108 to 120. The respiration during May varied from 30 to 36. No organic changes, except those of lung, were found, and no diagnosis was arrived at except of "suppuration." He gradually sank, and died May 21st. The medicinal treatment consisted of stimulants and tonics, and for the pain bromide of potassium and chloral and opium plaster to the loins.

Necropsy twenty-two hours after death.—Much emaciation. Adhesions between dura mater and pia mater in parts over vertex. The grey matter over an area about the size of a florin, and located in the marginal and superior anterior frontal convolutions of the left side, was totally disorganised. In similarly softened condition was an area of about the same size situated in the right inferior surface of cerebellum, chiefly in the slender lobe, but in this part the membranes were absorbed over a space three-quarters of an inch by a quarter of an inch; a broken-down nerve substance was in contact with the bone. The arteries at the base of the brain seemed normal, as did the rest of the encephalon. It was remarked that the left side of the skull was flattened (probably congenital). The heart was fatty, valves were normal; the kidneys also were normal. There were old adhesions in the right pleura, especially at the base. Both lungs were riddled with nodules of caseation about the size of peas. There were also many miliary tubercles. The left lobe of the liver, the cardiac end of the stomach, and the spleen were adherent by fine firm bands of fibrous tissue. There were no signs of recent inflammation. The stomach was firmly adherent to the spleen over a circular area about the size of a shilling, and at this spot the coats of the stomach were so thin that on removal the stomach separated from the spleen leaving a round patch of mucous membrane adherent to spleen. The left lobe of liver was much flattened. The spleen (which, together with the stomach and part of left lobe of liver, weighed forty-nine ounces) was about the size of a cocoa-nut. Its capsule was thick and purple, mottled with red, and round patches of yellow corresponding with the caseous nodules with which the spleen was filled. The spleen was transformed into a collection of caseous nodules, each about the size of a pea, these apparently being converted Malpighian bodies, and between these ramified fibrous tissues and bloodvessels. The stomach appeared healthy but thinned, especially at the cardiac end. The liver, which weighed forty-eight ounces without the piece of left lobe, was fatty and fibrous. Two caseous masses were found in upper surface of right lobe, and another in quadrate lobe; adjacent to each were dilated bile-ducts containing viscid secretion. In the head of the pancreas was a caseous mass about the size of an ordinary marble.

SOUTH STAFFORDSHIRE HOSPITAL.

A CASE OF SCIRRHUS OF THE BREAST IN THE MALE.

(Under the care of Mr. KOUGH.)

E. B—, aged forty-five, was admitted March 9th, 1880. Nearly three years ago a tumour of the size of a pea was noticed in the left mamma. It gradually increased till it acquired its present dimensions, but caused no pain till January, 1880. He then felt shooting pains passing upwards, to the neck. In February the patient sought advice, and was admitted into the hospital as soon as he could leave his employment. There is no history of injury or eruption about the breast or discharge from the nipple.

On admission the tumour was the size of a large egg; it was of stony hardness, adherent to the skin, but movable on the pectoral muscles. One gland at the anterior fold of the axilla was enlarged. The patient's general condition was fair, although he said he had lost flesh lately. The family history was indefinite.

On March 11th the tumour was removed by two elliptical incisions, and the axillary glands were enucleated. Owing to the adherence of the skin to the surface of the tumour a somewhat large wound was left. This had nearly healed by granulation by April 20th, when the patient was discharged.

The physical and microscopic examination of the tumour showed it to be scirrhous. There is no reason to believe that the axillary gland was infiltrated with cancer.

The case is interesting as forming a unit in the statistics of cancer of the male breast, but it also has some points of interest when read with similar cases published in the "Hospital Mirror" of THE LANCET, the "Transactions of the Medico-Chirurgical Society," and elsewhere. (1) The growth was noticed when it was very small. (2) It occurred after the period of physical perfection. (3) It was attributed to no physical cause. (4) Mr. Birkett states that in the male cancer of the breast is less rapid in its course, and slower in its recurrence, than in the female. This was slow in its growth, and it will be interesting to note whether it will return.

COTTAGE HOSPITAL, MORETON-IN-MARSH.

CASE OF OVARIOTOMY; RECOVERY.

(Under the care of Mr. JOHN N. MOORE.)

Mrs. P—, aged forty-nine, was admitted on April 22nd, stated that, until two years ago, she had enjoyed fairly good health. She began to menstruate at twenty. She had had two children, both of whom were living, aged seven years and ten years respectively. The catamenia stopped about two years ago. In May, 1879, she first noticed a tumour about the size of a four months' fœtus just above the pubes; the swelling was perfectly uniform, and exactly the shape of a pregnant uterus. She stated that she had occasional shooting pains through the pelvis, and afterwards distinctly felt the movements of a child. The tumour gradually increased in size until the abdomen became much distended, and the pressure of it caused the legs to swell, and interfered with the breathing and the power of locomotion; micturition was not affected in any way, but there was a constant sanious discharge from the vagina.

On March 4th, 1880, Mr. Moore tapped the tumour, to relieve the urgent symptoms, and drew off four gallons of semi-transparent straw-coloured fluid. This gave great relief, and was followed by no bad symptom except a marked depression of strength for a few days. The tumour commenced to fill again, and on April 22nd she was admitted into the Cottage Hospital. Two days later ovariectomy was performed.

The patient was placed under the influence of the chloroform and ether mixture (in the semi-recumbent position); an incision was made in the median line from the umbilicus to just above the pubes, dividing the layers of abdominal wall down to the peritoneum, which, when exposed, was found to be thickened in character and roughened. The peritoneum was carefully divided on a director, and the anterior surface of the cyst wall exposed. It was adherent to the anterior wall of the cyst by recent adhesions, which were easily broken down by the hand. At this stage a large trocar was plunged into the tumour, and a little over a gallon of thick, dark-coloured, gelatinous fluid was drawn off. It was then found on attempting to lift the tumour that there were lateral pelvic adhesions, one being of an exceedingly firm character. These were carefully broken through by the hand and finger-nail, and the tumour got free. The mass was then raised through the wound, exposing the pedicle, which was about three inches long by an inch broad. A needle, armed with a double ligature of Chinese gimp, was then passed through the centre of the pedicle and tied on either side, and afterwards completely round "the pedicle," which was then cut short and dropped into the abdomen. In breaking through the lateral adhesions there was an escape of fluid into the peritoneal cavity. This was carefully sponged out, the omentum replaced *in situ*, and the edges of the wound were brought carefully together by four deep and six superficial sutures, the former including the peritoneum. The wound was dressed in a simple manner by dry lint, the edges of it being supported by broad strips of Leslie's adhesive plaster, and the whole secured by means of a broad flannel bandage.

The after-treatment consisted in careful attention to the bladder, the administration of small but frequent quantities of gruel and milk and a little iced champagne to allay the sickness, which was of a trifling character. The temperature never rose beyond 102° F., and that forty-eight hours after the operation. The deep sutures were removed on the fifth day, by which time the wound had completely healed. No medicine was given at all, with the exception of two single pills, containing a grain of opium, on the night of the operation.

On examining the tumour after its removal it was found to be a composite ovarian, one large cyst, together with a solid substance, containing several small cysts, and weighed about five pounds.

No special antiseptic treatment was adopted; there was no hæmorrhage or vessel of any kind requiring ligature, and the patient made a rapid and complete recovery, leaving the hospital on the twenty-sixth day after operation.

Valuable assistance was rendered in the operation by Dr. Yelf (one of the surgeons to the hospital), Mr. Moore of Bourton-on-the-Water, and Surgeon-Major Crisp, A.M.D.

Reviews and Notices of Books.

Lessons in Gynecology. By WILLIAM GOODELL, A.M., M.D. London: Baillière, Tyndall, and Cox.

THE name of this book fairly describes it. It consists of short clinical lectures delivered, in many if not in all instances, at the bedside or in the operating theatre. The author in his preface says: "This book is not a treatise upon diseases of women, but mainly the outcome of clinical and didactic lectures delivered to the advanced students of the medical department of the University of Pennsylvania." Still most of the diseases peculiar to women are treated of. The author has been long known as an able and original worker in the obstetric department of medicine, but no one can read the book before us without feeling that he is also a very able teacher—that is, that he has the power to convey his views clearly to, and to impress them deeply upon, his hearers. His style is terse and pointed, and, without elaboration and in short space, he draws a striking picture of a disease. Originality of matter is not to be expected of a teacher educating students, but there are things which we have a right to expect of him—his teaching should, in so far as possible, be correct, and should be free from evil or dangerous tendencies.

There are subjects treated of in this volume with regard to which the opinions of experienced physicians widely differ, such as displacement of the uterus, lacerations of the cervix uteri, &c.—subjects upon which each one must form his opinion upon the evidence at his command. Dr. Goodell holds flexion of the uterus of a certain degree—be it backwards or forwards—as a pathological condition. In the treatment of anteversion he recommends, among other means, the use of stem pessaries. Now this method of treatment is, unfortunately, one of those subjects upon which opinions are widely asunder. There is, however, one fact about which there can be no doubt, and all are agreed—namely, that death has in many instances followed the introduction of stem pessaries into the uterus. Whenever the use of stems is recommended, this important fact in their history should be made known. The author makes no mention of it, but contents himself with referring to two cases of his own, in one of which "a smart attack of peritonitis," and in the other "a pelvic soreness," followed the introduction of a stem!

Again, we cannot help regarding the manner in which the employment of the curette is recommended for the removal of fungosities supposed to be present in the cavity of the uterus as hazardous. That fungosities are sometimes present in the uterus there is no manner of doubt, yet post-mortem examination shows how rarely they occur. Moreover, their detection during life is very difficult, for they cannot be easily recognised by the finger introduced into the dilated womb because of their softness; every gynecologist knows how liable small mucous polypi in the cervix of the uterus are to escape the sense of touch, and how the sight is necessary for their detection. We cannot but think also that in many instances pieces of tissue which have been removed by the curette, and regarded as fungosities,

are nothing but portions of the mucous membrane of the uterus, for on examination they have presented a structure precisely similar to that membrane. They may be present, moreover, with or without symptoms, so that it is by no means established that they are often the source of the mischief which has been ascribed to them. From this book one would be led to think that fungosities giving rise to symptoms are of frequent occurrence. In describing the preparation of the patient for Emmet's operation for laceration of the cervix, the author says: "Whenever the catamenia are profuse the preliminary use of the curette is always good practice." From what is well known of the result of interference with the interior of the uterus, we cannot help regarding such advice as reckless and highly dangerous.

There is one other subject to which we must call attention—namely, sexual relations as causes of uterine diseases. This is repeatedly referred to in the course of the work and at the end a special "lesson" is devoted to it, in which several scriptural characters, together with an apostle, are summoned to support the author's views. This subject may be one of the highest importance medically, as it is socially and morally, but we have no evidence regarding it which justifies us in forming an opinion. Whether the result would repay an investigation into so nauseating a subject surrounded by such peculiar difficulties we do not pretend to say, but we cannot hesitate to assert that the subject is too offensive to be touched upon now and then. Like a stinking cesspool, it should be opened, once for all set right, and closed, so that its foulness may not pollute its surroundings. This can only be effected by an exhaustive investigation of the subject, and thus setting it on a scientific basis. The author has not done this. The lesson referred to contains little that is scientific, little or nothing that the moralist could not teach; indeed the author, from the highest motives, has played the part of the moralist under the guise—and a very thin one—of the physician. We think this a mistake, for it can lead to no good to morality or medicine. Until the subject can be treated in a scientific manner, by the physician as such, it had better be left untouched.

On Aneurism; especially of the Thorax and Root of the Neck. By RICHARD BARWELL, F.R.C.S., Surgeon to Charing-cross Hospital. With Illustrations. London: Macmillan & Co. 1880.

THE practice and success of Mr. Barwell in this special department of surgery have already been brought under the notice of the profession in papers at the Medico-Chirurgical Society, but the subject is so important and his success has been so signal, that we are glad to welcome this little book, which will make the facts more widely known than they could otherwise be. Mr. Barwell has performed the double distal ligature for innominate aneurism four times, and is able to report that in three cases cure resulted. This is a success quite new to surgery. The result is attributed to the use of a new flat or ribbon ligature and the Listerian dressing. Although Mr. Barwell is a warm supporter of Listerism, he is strongly impressed with the imperfections of the carbolised catgut for ligatures, and proposes to replace it by a ribbon ligature prepared from the fresh aorta of an ox. It is stated that this ligature is organised in the body, and that being flat, it is used without severing any of the coats of the artery. He has employed it for the ligature in continuity of the largest arteries of the body seven times, and in no case has any trouble arisen from the ligature, and all the cases have done very well. Unfortunately the ligature is unsuited for divided arteries, and we note that Mr. Barwell does not give evidence to show that the coats of the vessels are not severed by this flat ligature. We are presented with a very gloomy picture of the pain attending the treatment of aneurism by compression; in view of the many rapid re-

coveries under Esmarch's bandage it appears to be an exaggeration to speak of the ligature as a pleasanter mode of treatment. We are surprised to read that the risk of gangrene supervening on the ligature of an artery for aneurism "has not been previously mentioned." A reference to the works of either Erichsen, Holmes, Bryant, or even to the handbook of Fairlie Clarke, would have saved Mr. Barwell from an error which, however, is too obvious to be harmful.

The Lancet Commission ON ATHLETICS.

II.

ATHLETICISM, like every other pursuit, does not pass scathless from the attacks of its enemies. It is objected to as injurious both on social and physical grounds. In the first place, it is alleged that it unfits men, especially young men, at the University, for reading and steady work, and improves the body at the expense of the intellectual powers. Certainly, a man may be so passionately devoted to athletic exercises as to be willing to give up everything else for the pleasure of this one pursuit. But the same is to be said of every other amusement, and the proper use of a thing should not bear the blame that attaches to its abuse. It must be granted, however, that during the Race-week at the University, and for a short time preceding it, a man in hard training usually feels rather restless, and in such admirable spirits that he finds it hard to apply himself to any distasteful work; but this state lasts for a very short time, and, we believe, does more good by varying the monotony of the system than harm by the temporary interruption it may cause to the routine of work. But that even severe physical exercise is not inconsistent with hard work and success in intellectual pursuits is demonstrated by the fact that many men who have been renowned as oarsmen have taken the highest honours at their University, or afterwards reached positions of eminence only attainable by the most cultivated intellects. Amongst these we may mention C. Wordsworth, late Bishop of St. Andrews; the late Dean of Norwich, Dr. Garnier; C. Merivale, author of "History of the Romans under the Empire"; G. A. Selwyn, late Bishop of Lichfield; W. W. Smyth, late President of the Geographical Society; Justice Sir W. Balliol Brett; Justice Hon. G. Denman; F. T. MacDougall, late Bishop of Labuan, Fellow of the Royal College of Surgeons, England; Dr. Hornby, Head-master of Eton. Besides, it appears from Mr. MacMichael's biographical notice of University oars that of the 190 gentlemen who took part in the contests between the years 1829 and 1861 no less than seventy-nine highly distinguished themselves in after-life at the Bar, in Medicine, in the Church, or in literary pursuits, or took a good degree at the University. But even if the accusation that rowing diminishes the intellectual powers were true (and the examples we have quoted show the contrary), would not the injury be more than outweighed by the unquestionably good influence which it exerts on the *morale* of men who make it their exercise? Training is another word for the strictest sobriety and self-denial, and in no branch of athletics is training carried to so great an extent as among rowing-men. It is no small matter for an undergraduate to give up during five weeks of the summer term all the small self-indulgences that make life pleasant; and any pursuit which makes hundreds of men willing converts to such self-denial must inevitably produce elevating results. Judging from the popular novels of fifty years ago, the tone of the universities has in many ways since then greatly improved. Loafing and inebriety, the virtues of the old university hero, are happily now rarely to be met with, and we believe that the improvement is due in a great measure to the increase of rowing and other athletic exercises, and the training which is their necessary adjunct. The river, too, is a school for endurance which cannot be surpassed. Even the most carping critic must have some admiration for a man who, for

bare honour, undergoes regularly the discomforts of training in an English spring to the end that he may take part in a contest which, temporarily at all events, will cause him severe bodily distress.

As to the question of health, however, considerable difference of opinion exists with respect to the effect that athletic pursuits carried to their full extent have, directly or remotely, on the constitution of the individual. As a rule, it may be stated that medical men who have been educated at the universities, or are practising in university towns, regard athletics with a favourable eye, whilst those practising in large cities frequently take a contrary view. This discrepancy of opinion is due to two causes. The University physicians see large numbers of men who, year after year, come up to the University engaged in severe athletic pursuits, and find that only an extremely small proportion are injured by it, whilst a vast number are distinctly benefited. The physicians in a large town see only the exceptional cases of breakdown, and not having the opportunity of witnessing the corresponding advantages, are unduly impressed by them. Moreover, the undergraduates of a University as a body are the least likely to feel the ill effects of prolonged and violent muscular exertion. The majority of them have had a long training from boyhood in all kinds of sports and exercises, and by the time they come to the University they are pretty conscious of what their powers are, and consequently we find that those who engage in athletic pursuits at the University are those who physically are best fitted to endure the strain. With a town population the case is different. In the majority of instances athletic feats are undertaken without any previous physical preparation; the pursuit is taken up generally later in life than is the case with the Universities, and often with a view to strengthen failing health. Then, too, the conditions of life of the athlete in town are very different from those of the undergraduate, who is well fed, well housed, and takes his exercise at hours when his bodily powers are not exhausted by the fatigues of a day's business or confinement in close, ill-ventilated chambers or offices. The townsman's meal-hours are more irregular, and his meals are perhaps eaten with less relish. The opportunities for exercise, too, are not constant, and periods of violent exertion alternate with corresponding periods of sedentary occupation. Taking all these circumstances into consideration, it will be seen that the townsman is heavily handicapped when he engages in athletic pursuits, and it is not to be wondered at that breakdowns more frequently occur than is the case at the Universities. In making these remarks we do not intend to throw any discouragement on the pursuit of athletic exercises in towns, but merely to point out that the conditions under which they are followed are different from those obtaining at the Universities, and therefore more care ought to be exercised in selecting any special pursuit, and particular attention should be paid to the circumstances under which it can be practised.

Our remarks, therefore, in the present article, will be confined to the influence athletic exercises have generally on the health and constitution of town populations, more especially as affecting those dwelling in large towns, contenting ourselves with endorsing Dr. Morgan's opinion,¹ that as far as any injurious effect can be traced to violent athletic exercises among men at the University, they can be accounted for "by too great a strain being laid upon the system in early life, or that the harm may generally be accounted for either by the existence of constitutional unsoundness, or by some deviation from the commonly accepted laws of health and prudence." Moreover, we may quote Professor Humphry's assurance, that undergraduates are, "as a general rule, when not under the eyes of their parents, cautious enough in what concerns their health . . . they are prone to seek advice when they are in doubt as to their fitness for boating, and are for the most part willing to follow it, provided they feel that it is unprejudiced, and grounded on the real merits of the case. Being regarded as responsible agents, and allowed to judge for themselves, they are amenable to reason, and usually take the right course."²

¹ Dr. Morgan finds that from the year 1829 to 1869, both years included, 294 men have rowed in the Inter-University race; of the 294 oars 17 either describe themselves, or are spoken of by their relations and friends, in some cases with considerable reservation, as having suffered from their labours.—Vide University Oars, by John Edward Morgan, M.D. Oxon., F.R.C.P.

² Extract from a letter of Professor Humphry, quoted in Mr. MacMichael's Chronicle of the Oxford and Cambridge Boat Races from 1829 to 1869, pp. 26.

In forming an opinion as to the effect that certain athletic pursuits may have on the health of the individual a variety of circumstances have to be taken into consideration. Age, conformation, and habit of body, constitutional tendencies, &c. No man in his senses would think of taking to the running path after thirty, and few would be injudicious enough to allow rapidly-growing lads of thirteen to fifteen to engage in athletic exercises which throw a severe or prolonged strain on the muscular and osseous systems, as boat-racing, alpine climbing, or severe pedestrian exploits. Nor do we find men with large frames and a powerfully-developed muscular system generally engaging in athletic pursuits that require great dexterity or celerity of action. Moreover, the form of exercise pursued should in all cases be subordinated to the power of the individual and the peculiarities of his constitution. A man would act most unwisely who, with the knowledge that certain members of his family had suffered from heart disease or consumptive tendencies, should undertake an exercise that would throw any undue strain upon the heart or lungs; but he might, with great advantage to himself, adopt other athletic pursuits that would harden his frame and perhaps enable him to ward off his hereditary tendencies. The introduction of golf and lawn tennis among athletic pursuits are in this respect a great boon to the feeble members of the community, not merely to those whose health prevents them from undertaking more vigorous exercise, but to those whose strength is failing through age. Again, a medical man, without any inconsistency, may prohibit the rough-and-tumble game of foot-ball to a youth of strumous tendencies and yet permit him to play cricket, since in the first game there would be danger of inducing joint or bone disease from some comparatively slight bruise or strain inseparable from the game, whilst such accidents are comparatively rare in the latter pursuit. The great point, therefore, in every case is to determine what the effects a particular exercise will have upon the individual, and, having decided upon the proper form of exercise, to proceed to form some opinion as to the amount that should be taken.

With regard to this latter point, we fear more difficulty will be experienced than in determining the form of exercise that may be adopted. Estimates have been made, based on chemical and physiological observations and mathematical calculations, showing the amount of work a man weighing 150 lb. can accomplish in eight hours' vigorous occupation at different kinds of labour. Thus eight hours' pile-driving is equal to the force expended in lifting 312 tons one foot in height; turning a winch for the same period equals 374 tons lifted one foot; walking one mile on the level, unloaded, is said to be equivalent to lifting 17·67 tons one foot; but if loaded with a knapsack weighing 60 lb. the work done in a mile's march amounts to 24·75 foot tons. However correct the mathematical calculations and the chemical and physiological observations may be on which these estimates are founded, still, when pushed beyond the limits of common sense, they become dangerous in their application, because they ignore what, for want of a more expressive phrase, we may call the "stamina" of the individual. It is impossible from scientific data at present before us to explain how it is that the Hindoo coolie,³ with his slim muscles and rice diet, will perform an amount of external mechanical work that the English navvy, with his grand muscular development and ample diet, would find it difficult to excel. The estimate, therefore, of the amount of exercise that may be taken without injury to health in any given case is not to be decided by any hard-and-fast rule, but by observation of the effect that exercise has on the health and development of the individual. And here we would remark, parenthetically, the great advantage it is for schools to have a medical attendant who not only visits the boys when sick, but is constantly brought into contact with them when in health. It is in boyhood that the physical powers are first tested, and it is of the utmost importance that the experiment be fairly watched. We do not advocate any fussy interference with boys' sports and games, but we do think an eye should be kept on them to see that

they do not "take too much out of themselves." This could easily be done if the height, weight, and chest girth of each boy were taken from time to time during the half year. So long as the weight increased in a normal ratio for the boy's age, no apprehensions need be entertained; but a retrogression or even a pause would be the signal for placing a lad under surveillance as regards his work, mental as well as physical. With respect to adults, the rule should be that exercise should stop short of fatigue. When a feeling of painful effort is experienced in the performance of any work we may be sure that the nervous system is becoming exhausted, and that ere long symptoms of acute local fatigue will manifest themselves. These, as regards the muscular system, are recognised by irregular, painful muscular contractions known as cramp, and by a peculiar tremulous quivering and twitching of the muscles. When fatigue is carried so far as to affect the respiratory and circulatory systems, the symptoms are of a graver character. Panting, sighing respiration, rapid and irregular action of the heart, cold sweat, and frequently giddiness and indistinctness of vision, show that the physical powers have been pushed beyond the physiological limit. A judicious trainer, therefore, will cry "Hold! enough," at the first symptom of fatigue, and content himself by gradually developing the powers of endurance, carefully increasing the task in accordance with the increase of the muscular power; but, above all, with the establishment of that concordant action of the heart, lungs, and great vessels which is so essential to development of a man's "breathing power" in fast work.

Regularity and constancy in the pursuit of exercise are imperative if perfect health is expected to result from its employment. It is far better for men to lead altogether a sedentary life than to be irregularly active. This caution is the more needed since the transition from sedentary habits to arduous and exhausting physical labour is of frequent occurrence. Dr. Kalfé, in some remarks on this subject, has pointed out that "Every year a number of middle-aged men, who, for some months past, have been engaged in the sedentary occupations of a profession, of literature, or of business, at the commencement of the autumn holiday start for the Continent or the Highlands, and suddenly undertake immense fatigue in the ascent of alpine heights, or no less laborious work of a day on the moors without the least preparation. So also we see every Bank-holiday crowds of young men starting off for some tremendous walk or 'bucket' up the river, utterly unprepared for the task they undertake. Is it to be wondered at that men return complaining that their holiday has done them no good; that, instead of vigour, they complain of exhaustion; that their appetite fails them, their nights are sleepless, their limbs ache, and they are jaded and spiritless?" Again, the transition from active habits to sedentary pursuits is generally accompanied by a marked disturbance of health, since organs roused to full activity by the stimulus that exercise gives them are liable to become "functionally deranged" when that stimulus is withdrawn. This, perhaps, would not be so frequently observed if instead of relapsing immediately, as is too frequently the case, into idle habits as far as exercise is concerned, an attempt was made to engage regularly, for however short a time, in some pursuit which would ensure brisk muscular movement; so that the health acquired by exercise during the vacation should not be lost; and moreover that the body, when the next holiday period came round, should be found in fair condition to undertake the increased physical strain then thrown upon it.

New Inventions.

THE UNIVERSAL INVALID TUBULAR WATER-OR AIR-BED.

MESSRS. POCKOCK Brothers, of London, have manufactured, at the suggestion of Dr. Miller of Bethnal House, a very serviceable water- or air-bed. Instead of having the air or water contained in one large chamber, it is in several separate tubes held together in a case. The cylinders are of course waterproof, and those in the centre of the bed are provided with an additional coating of macintosh. The tubular structure allows of free ventilation and of draining of fluid from the surface of the bed. The separate tubes can be

³ Professor du Chaumont, of Netley ("Parkes's Hygiene," 5th edition), has given some interesting particulars of the work done in India by natives. (1) Thus a hill coolie will go thirty miles, with an ascent of 5500 feet, in three days, carrying 80 lb. weight, the weight carried on a frame supported on the loins and sacrum, and aided by a band passed round the forehead—work per diem, 500 tons lifted 1 foot. (2) Eight palanquin-bearers carried an officer weighing 180 lb., and the palanquin weighing 250 lb., twenty-five miles in Lower Bengal; assuming each man weighed 150 lb., the work was 600 foot-tons per diem.

more or less inflated to raise or relieve from pressure certain parts, while the removal of a couple of the tubes permits of the easy use of the bedpan. It is free from noise and surging, and is of course easier to arrange and move than an ordinary water bed. Another great advantage in it is, that an injury to any one tube requires the repair or renewal of that part only. The bellows for inflating the tubes supplied with the one submitted to us is far too small; with a larger one the process of inflation would be much easier.

GOUDIE'S PATENT MATTRESS.

WE have received from Messrs. Taylor Bros. and Co., of Queen Victoria-street, one of Mr. Goudie's new cork and air mattresses. When inflated it resembles in appearance a thick horsehair or spring mattress, the air chamber being surrounded by a fairly thick casing of granular cork mixed with "a powerful but inodorous disinfectant."

The advantages Mr. Goudie claims for his patent mattress are:—It is cheaper than hair or feather, is less liable to get out of shape than hair or wool, maintains a more even temperature than air- or water-beds, and is as soft, but not so liable to be damaged, and is lighter than, and equally as durable as hair. It is non-hygrometric, and does not cause chills, as when the india-rubber is exposed. The mattress can be purified after use by immersion in water mixed with any disinfectant, and will dry in twenty-four hours in a temperature of 60°. There is no smell of india-rubber, nor the uncomfortable "spring" of an ordinary air- or water-bed. For ordinary use it is both comfortable and healthy, but it hardly fulfils the object of an air-bed in cases requiring an even distribution of pressure over the whole body, as it is not flexible enough to fit closely into the surface of the body.

Analytical Records.

MISTURA BISMUTHI CO. (DR. BROWNING'S).

(MACKAY, MACKAY, & CO., BOUVIERIE-STREET.)

A good and useful preparation. It is intended for use in dyspepsia, sickness, gastric catarrh, &c. Bismuth could hardly be given in a better form.

MIST. PEPSINÆ CO. C. BISMUTHO.

(C. J. HEWLETT & SON, LONDON.)

Contains pepsine, solution of bismuth, purified solution of opium, hydrocyanic acid, nux vomica, &c. It is clear, mixes easily with water, and is undoubtedly a valuable and convenient preparation.

ESSENCE OF DANDELION COFFEE.—ESSENCE OF COFFEE AND CHICORY.—THE EDINBURGH COFFEE AND MILK.

(T. SYMINGTON, EDINBURGH.)

The taraxacum extract is really an excellent substitute for coffee, and will, we think, be an advantage to many bilious and dyspeptic patients.

Edinburgh Coffee and Milk is a mixture of condensed milk with coffee essence. It is convenient, and will be useful to travellers, yachtmen, and others.

BENGER'S PREPARATIONS OF THE NATURAL DIGESTIVE FERMENTS.

(MOTTERSHEAD & CO., MANCHESTER.)

Liquor Pancreaticus (Benger); Liquor Pepticus (Benger).

These are carefully prepared, and, so far as we can tell from the tests we have been able to use, thoroughly trustworthy preparations. So many worthless articles of the kind have been sold that great care is required in choosing those upon which reliance can be placed. Mr. Benger's care has therefore been well spent.

MCDUGALL'S PATENT FLOUR (SELF-RAISING).

(MCDUGALL BROS., LONDON & MANCHESTER.)

This is an interesting, and as far as we know, perfectly original method of treating and improving flour. During the process of milling, and afterwards during the ordinary fermentation-process of baking, the flour suffers, as is well-known, a definite loss both of phosphates and of nitrogen. The new process, which is the subject of a patent under the joint names of Professor Horsford, Cambridge, U.S.A., and Messrs. McDougall, consists in the mixture of the flour with bicarbonate of soda and dry acid phosphate of lime. The addition of water causes the formation of the phosphates of lime and soda, and the raising of the dough is effected by the carbonic acid liberated from the alkaline carbonate. Thus the phosphates lost in milling are restored, and the destruction of gluten attendant upon fermentation prevented. The bread, pastry, &c., made with this flour are very light and sweet, and the making of bread becomes very simple. The process appears to us to be one of great value and importance.

FARR TESTIMONIAL FUND.

To the Editor of THE LANCET.

SIR,—I am desired by the Committee for the Farr Testimonial Fund to request your further valuable assistance by publishing in your next issue the enclosed Second List of Subscriptions to the Fund.—Faithfully yours,

Aug. 2nd, 1880.

NOEL A. HUMPHREYS, *Hon. Sec.*

Humphreys, General Register Office, Somerset House, London, W.C. All cheques or post-office orders should be crossed "Martin and Co."

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1880.

THE reports of the deputation of representatives of the British Medical Association, on the subject of medical reform, of their interview with Earl SPENCER and Mr. MUNDELLA, are of a character to warn medical reformers that the work which has been well begun by a Conservative Ministry, is in strange danger of being abandoned by a Liberal Administration, which is without a *raison d'être* if it abandons the task of putting wrong things right. It is a novel and curious thing in history to hear a man of Mr. MUNDELLA'S stamp speaking comfortably to the enemies of improvement, and very discouragingly to the friends of progress and beneficial change. If we might venture to give Mr. MUNDELLA a little advice—we know the low esteem in which gratuitous advice is generally held—it is to abandon this rôle at once. He plays it badly. Words of cold discouragement to those who have brought a reform movement to the very verge of success come with doubtful grace from him. He should leave them to others, though in the ranks of the Conservative camp there could scarcely be found a man to make the representations which he made to the deputation of the British Medical Association on Saturday. The profession knows Mr. MUNDELLA well enough to believe that he did not intend to act so. But whatever he intended, this is the result, and his answer in the House of Commons to Mr. ERRINGTON, and his remarks to the deputation, have filled every opponent of medical reform with new hope that the long-delayed and much-needed Amendment of the Medical Acts is going to be indefinitely postponed. What will happen next? Mr. MUNDELLA speaking comfortably to the defenders of old corporations, and of a useless, wasteful, costly Medical Council! The times are out of joint. We shall soon hear of Dr. ANDREW WOOD among the Radicals of Edinburgh, presiding at a banquet to celebrate the defeat of the House of Buccleuch and the reign of Mr. MUNDELLA.

But let us analyse a little more closely the reply given by Lord SPENCER and Mr. MUNDELLA to a deputation asking, most reasonably—though perhaps at an unseasonable time—that a piece of reform commenced by the late Conservative Ministry should be completed by the present Government. Lord SPENCER spoke of the difficulty of the question of medical reform, and of the opposition which measures to promote it excited: "Measures of this kind appear to create very considerable difficulty and opposition," and "unless there is something like general concurrence of the medical profession in England, I do not think it would be wise to attempt it." Lord SPENCER would surely admit that no measures worth passing are ever passed without "considerable difficulty and opposition"—certainly not by a Ministry in which he has so proper a place, both on personal and hereditary grounds. As regards the "general concurrence of the profession," which he requires to see in order to justify the Government in undertaking the measure—this is the very state of matters that

exists. There is not only general concurrence, but almost absolute unanimity. It would be impossible to find a profession more "agreed" than ours on the simple and urgent points of medical reform—(1) consolidation of the examining boards, and (2) a Medical Council representing the profession and capable of carrying out with authority its own decisions. On the one side of this question is the profession—agreed, harmonious, unanimous; on the other, are nineteen competing, interested, and in a few instances perfectly antiquated bodies, which have outlived the circumstances in which they were required, and even a few of these are on the side of reform, or prepared to accept what they know to be inevitable. But—and here we come to Mr. MUNDELLA—the Vice-President tells us, as an argument against the Government settling this question, "the existing examining bodies have a number of representatives in the House of Commons, and unless there can be some common agreement among the profession, it is utterly impossible for any Government, however strong, to carry it out. I find Medical Bills always defeated by the action of medical men themselves." Surely Mr. MUNDELLA, when the recess comes and he has time to think over these strange representations, will regret them. We did not know that the examining bodies had representatives in Parliament, except the Universities, which we cannot suppose will at the last oppose changes recommended by a Select Committee. But even if it be so, even if Dr. PLAYFAIR and other university representatives are putting the drag on, which we do not believe, has the great medical profession no representatives in Parliament? Let Mr. MUNDELLA give the answer. "They have always defeated medical Bills." If they can defeat Bills, they can, with the help of a good Government, pass Bills. They have defeated Bills simply because the Bills have never pretended to do what, in the unanimous judgment of the profession, needed to be done. Let the Government now in power complete the investigation two-thirds accomplished, and bring in a Bill dealing with the whole question, and it will find the profession has representatives in Parliament as well as the examining bodies, and a great question will be well settled, with credit to the Ministry that helps to settle it.

ALTHOUGH in some of the lower animals it has been shown that the spinal cord, after division, may reunite, all attempts to obtain this result in the case of dogs have hitherto failed. It is possible that this is to be ascribed to the age of the animals on which the experiments were performed. EICHORST, experimenting upon very young dogs, has succeeded in obtaining union of the cord and partial restoration of function, in a comparatively short space of time. Although successful in only one case, the particulars of the experiments are of much interest.

In three young dogs the spinal cord was divided between the lower part of the dorsal and upper part of the lumbar regions. Immediately after the operation there was, of course, complete motor and sensory paralysis of the parts supplied from the cord below the section, and vigorous reflex movements could be obtained. The wounds were treated on strict antiseptic principles, but thymol was employed instead of carbolic acid, on account of the action of the latter on the nerve-tissues. The first animal experimented on died in twenty-one days, without any return of

voluntary power or of sensation in the paralysed parts. The post-mortem examination showed that there had not been the slightest attempt at regeneration of the divided cord. The ends were three millimetres apart, and were united by a grey translucent gelatinous substance which was in intimate organic connexion with each extremity. This intermediate tissue consisted of large round cells, containing nuclei which were deeply stained by carmine, and a finely granular interstitial tissue which could be resolved, by a high magnifying power, into clear granules and fibres. There were numerous capillary vessels, the proper wall and adventitial sheath of which were permeated with elongated oval nuclei. Nowhere could any trace of nerve-elements be discovered. It was a cicatricial tissue closely analogous to that of the neuroglia. The nerves of the lower extremities presented no structural alteration.

In a second dog operated on in the same manner, a return of voluntary movements commenced at the end of the fourth week. The dog became able to stand, sit, and finally to run 180 feet without interruption, although its movements were distinctly ataxic. Sensibility, however, remained absent. The animal was killed on the thirty-fifth day. A greyish substance, somewhat flattened from before back, had restored the continuity of the cord. That part corresponding to the anterior and lateral columns already presented a medullary aspect. The nerves and muscles of the lower extremities were normal. Microscopical examination of the new tissue in the cord showed it to be permeated by tracts of nerve-fibres, running from above downwards, of which most possessed a medullary sheath. Many of the fibres presented nuclei which had the aspect of being pressed into the fibres from their surface. Non-medullated nerve-fibres were less abundant, and showed a tendency to a varicose condition. The two kinds had no regular distribution. The interstitial connective-tissue presented cellular elements, colouring deeply with carmine, and provided with processes. Besides these, there were two very large cells with double contoured nuclei and large processes, but whether nerve-cells or connective-tissue elements it was impossible to say.

In the third dog, although it lived for 131 days after the operation, there was no renewal of the motor or sensory functions, nor was there any restoration of the continuity of the cord. The extremities were two millimetres apart. In neither animal was there any secondary degeneration in the cord.

LET us go aside awhile, out of reach of the heart- and head-aching din, and the acrimonious disputation about the "nursing system" and "hospital management" at Guy's, and try to discover the principles involved, or at stake, in the contention. What makes it especially important to do this is the fact that whereas the grand engagement at a Metropolitan hospital is just now the centre of interest, the conflict on this particular field is only one episode in a campaign on the final issue of which the best interests of the sick poor, and of medicine as an art, if not also as a science, depend. We may tell the Governors of hospitals generally that Medicine has made the hospitals, and, if they think to succeed in rendering the simply administrative element, however philanthropic, the foremost feature in these establishments, they are mistaken, and not only in error, but engaged in a

ruinous enterprise, which is neither to be tolerated nor endured.

Hospitals are not charities to which Medicine contributes something, but, in a special sense, *medical* charities. Nor does medical aid consist of two parts, as certain members of the lay public would seem to suppose. It is not a combination of medicine and nursing, or nursing and medicine. The whole charity from first to last is *medical*. The sick poor are taken away from their homes, and are placed in an establishment which is—or should be—constructed and administered with a single eye to the complete and rapid cure of the cases admitted to its benefits. It is an engine of "cure," and the engineer should be—must be—an expert in the art of curing. This is the principle of the hospital system, and it is this which is at stake in the dispute. The lay governors of hospitals are trying to make these institutions houses of charity, and to treat the medical business as auxiliary! They wish to take charge of the sick poor and to nurse them, with or without the advice of the medical faculty; a corps of women who, in the energy of their discontent at the natural subordination of their sex, have seized on nursing as a sphere for the vent of their emotional natures—being the agents of this lay "sick-tending." The physicians and surgeons of the various hospitals are, forsooth, to be reduced to the level of practitioners called in by the governors to *advise* as to the treatment of their—that is the governors'—patients. It is well to state this plainly and clearly, and to let it be understood, in a cool moment of reflection, without the irritation produced by that special conflict of opinion which must occur in connexion with any particular case. Divested of personal attributes and considerations, the simple facts are as we have stated them—Hospitals are *not* homes for the sick, with medical advice as an adjunct; but institutions wholly medical in their character and purpose, and, therefore, they must be under direct medical control. We are not prepared to endorse or approve any half-measure or schemes whereby the medical faculty of a hospital is under grace of the lay governors to be allowed a muffled voice in the administration. Medicine must be paramount. If the present governors of these medical charities, the name and fame of which have been wholly made by the medical men connected with them, are not prepared to carry on the institutions in which they have a little brief authority on this footing, they must be taught by the logic and force of facts that these, and these only, are the terms upon which the medical profession will continue to regard the hospital as an appliance of *its* work and *its* charity.

We may seem to take high ground. We do so deliberately and after mature and even slow deliberation. The time has come to step outside the special circle of this dispute at Guy's, and appeal to the medical profession as a whole to declare itself on the question at issue. Without such action in concert as we now advise and invite, it is apparently impossible to make the matter clear to the governors of hospitals, who would seem to be, strangely, in the dark as to their actual position in relation to these charities. It has long been painfully evident that the committees of hospitals do not recognise the men who give time and skill to the service of a charity as among its principal contributors. The vulgar estimate of gold—as of higher value than money's-worth in

brains and power—pervades the councils of men who are simply the trustees of the money bequeathed or subscribed by the public for the cure of disease. That money has been left, or is given, to enable the medical profession to carry out its beneficent work as a body expert in the art of healing. The funds collected must, in common sense and fitness, be administered as the medical faculties of the hospital, the representatives of the profession in this matter, desire.

This should be self-evident; but let us look at the question in another way. The object is to cure, and the nursing of a patient is an integral part of his medical or surgical treatment. How then can it come to pass that intelligent and reasonable men presume to think they can fulfil the conditions of their trust by separating nursing from the rest of the treatment, and affecting to take it under *their* control? For ourselves, we must be excused for feeling some reluctance to intervene in this matter. We cannot help seeing the hand of NEMESIS in these differences and disputes between the governors of hospitals and medical gentlemen all over the country. It was a short-sighted as well as a scientific blunder to sanction the introduction of independent nursing sisterhoods into hospitals. What the true interests of the sick require is not the presence of misguided “ladies” hovering round their beds and taking every “opportunity” to proselytise, but a fair number of women of their own class, trained to do their business as nurses, humbly and honestly, at the bidding of the medical officers. How would it be if the dispensers of drugs were to decline the “modest” duty of making up the prescriptions given by the staff, and take to prescribing on their own account, being supported in their presumption by the governors? The creation of a class of “sisters” who are above the rank of nurses has been a mistake, and we are now reaping the consequences. Apart from this view of the facts, however, there is that which we have already propounded and trust to see debated temperately and quietly by members of the profession whose names will have weight. It is a great question, a practical and pressing one. Nothing but good can come of its being fully and freely discussed.

Annotations.

“Ne quid nimis.”

THE ILLNESS OF MR. GLADSTONE.

THE illness of Mr. Gladstone is a matter of huge public interest, and will be a sufficient excuse for us giving some medical particulars of it, and trying to get some lessons out of it. For a week or more before any decided symptoms declared themselves, Mr. Gladstone was showing signs of fatigue, and not looking well. On the night of Friday, the 30th ult., while dining with Lord Frederick Cavendish, he was attacked with rigors, and had to leave the dinner-table. After awhile he recovered, and went to the House, fortunately to find that it had just been counted out. On the Saturday Mr. Gladstone had another severe rigor, and Mrs. Gladstone went for Dr. Clark, who returned with her, and was fortunately just in time to see his distinguished patient descending the stairs, muffled up to the eyes in the collar of his great coat, and looking exceedingly ill, but on the point of joining the meeting of the Cabinet. Dr. Clark finding a temperature of 103°, and all the indications of an acute and critical illness, had to tell the Premier that he must not attend

the Cabinet. Mr. Gladstone is an eager man, but he knows the value of medical opinion, and submitted promptly. It is serious to think how much worse matters might have been had his keen sense of duty not been qualified by finding the House counted out on Friday, and by the opportune arrival and firmness of Dr. Clark on Saturday. Beyond rigor, high temperature, and the feeling and look of illness, there were no other marked symptoms. The pulse was quickened, but never exceeded 90, and was generally only 80, being, we believe, ordinarily steady and slow, even under animating and exciting conditions. Dr. Clark found, at his first visit, slight crepitation at the base of the left lung posteriorly, which, at subsequent visits, varied strangely in position, and suggested some septic element in the case. The facts continued much the same for several days without any marked development of the physical signs of pneumonia. For a day or two the temperature underwent a considerable remission in the morning—a fact which, in the absence of decided lung symptoms, gave a typhoid aspect to the facts. At intervals there were very profuse perspirations, which at first were attributed to the action of medicines, but which continued in the absence of medicines, and proved part of the natural history of the case, which may be regarded as a *febricula*, or short fever, occasioned by a chill. On Monday, at Dr. Clark's own suggestion, Sir William Jenner was called in and saw Mr. Gladstone. Occasionally, as on Sunday, the temperature fell even below 100° for a short time, but only to rise again in the evening. So late as Wednesday morning the fever facts were curious. At nine in the morning the temperature was 101°, and within an hour it had risen to 103°. In the afternoon it had fallen to 99°, and has not risen since, a drenching perspiration having happened before the fall. The treatment has consisted chiefly in absolute quietness and judicious support of the system; stimulants were carefully used, but not found helpful.

We cannot, speaking medically, acquit Mr. Gladstone altogether of the charge of having recently neglected to remember that even his powers have a limit; but it is to be said, to the credit of his judgment, that he has been a most submissive patient, and, to the credit of his splendid and well-preserved constitution, that he has passed through a testing illness without the slightest sign of failure in the great vital organs, and in a way to justify the hopes of his countrymen that he will, with a little more consideration for his physical needs, be long spared to play his conspicuous part in the councils of the nation. No illness since that of the Prince of Wales has produced such profound and universal anxiety. Mr. Gladstone will have the most refined sense of this interest, and cannot better recognise it than by taking a little more care of himself.

ROYAL COLLEGE OF SURGEONS.

AT the last examination for the diploma of membership of the College, which was brought to a close on Friday, after a fortnight's work, two hundred and thirty-eight candidates had been examined, of which number no less than ninety-two failed to acquit themselves to the satisfaction of the Court of Examiners, and were consequently referred to their studies for six months. Some of these young gentlemen have had considerable experience of these collegiate examinations, many of them having paid their respects to the examiners from twice to five times. Thirteen candidates passed in Surgery, and when qualified in Medicine will be admitted members of the College. Sixty-two of the 238 candidates held a recognised medical diploma or degree, and therefore had not to undergo another examination in Medicine; of these, 39 held the L.S.A., 7 M.B. Edin., 3 L.R.C.P. Edin., 2 M.B. Aberd., 2 M.B. Cantab.,

2 L.R.C.P. Lond., 1 M.B. Dub., 1 M.D. Malta, 1 M.B. Toronto, 1 M.B. Durham, 1 M.D. Berlin, 1 M.D. Paris, and 1 M.D. Ohio. The examinations for the present session have now been brought to a close, and before the next meeting of the Court a new member will have to be elected by the Council, in the vacancy caused by the resignation of Mr. Frederick Le Gros Clark, F.R.S. Mr. Clark was admitted a member of the College February 15th, 1833; elected one of the Honorary Fellows December 11th, 1843; a member of the Council in 1864; Professor of Human Anatomy and Surgery in 1867; a member of the Court of Examiners in 1870; of the Dental Board in 1872; and in 1874 the highest distinction the Council could confer—that of President of the College; and in 1875 Hunterian Orator; and well performed his duties as a member of Committees.

CONVALESCENT HOMES.

THE report by a Special Committee of the Charity Organisation Society on Convalescent Homes is a good illustration of the work of that much-abused though very useful society, and is well worth a study by those who wish to help judiciously the cause of such institutions. The report, with the accompanying catalogue, can only have been constructed with great labour, though it may be consulted with great ease. The charity that labours and takes trouble is almost more rare than the charity that gives. Many a person will fling a guinea to an institution who will decline to attend an annual meeting to investigate how the guineas are spent, or to visit the house of an applicant for his hospital letter to judge of fitness and to give a personal character to charity. The Charity Organisation Society has shown more of the disposition to take trouble than to give money. It has even gone to the verge of severity in its investigation and judgment of individual cases and charities, and in the exposure of that want of co-operation and of system which is so very injurious both to the patients needing help and the institutions which have help to give. The fear of imposition and the keen eye for unworthiness in the Charity Organisation Society have been more conspicuous even than the desire to help, as the latter is more conspicuous in individuals than the former. We want, however, both qualities if we are to make a successful effort to increase self-respect and diminish a vicious pauperism. We commend this report to the study of that large section of society who regard the Charity Organisation Society with at least coldness. They will get from the report much information, very carefully classified, concerning more than 150 convalescent homes, and will see some useful suggestions by the Special Committee for developing yet more the methods of furthering the convalescence of patients whose means are apt to be exhausted just as the wants of convalescence assert themselves. We are glad to notice and to corroborate two or three conclusions of the Committee. One is in favour of more accommodation for medical and surgical advice in Convalescent Homes than at present exists, for in many of them it is taken for granted that the convalescent requires no more medical or surgical attendance. They direct attention to the evil of long waiting for letters. This is a most painful and faulty feature of the present system. Patients are kept waiting weeks or even months for admission, and in doing so lose ground, and sometimes hope. What makes this more unsatisfactory is that we are never quite sure that the beds are fully occupied. The Committee kindly suggest that the offices of the Council be used for the present as an office for information regarding vacancies, conditions of admission, railway fares, &c. As we have said, a wonderful amount of information is given in the catalogue, under eighteen heads. There is need for one or two columns more. One great difference among Homes is the diet allowed to patients. The Committee suggest drawing up rules on this and other

hygienic questions. They would do great service by directing attention to such subjects, if not inserting in a column the diet-table of each institution. We cannot leave this subject without commending Convalescent Homes to the sympathy of the charitably disposed. At this season of the year, when the healthy and the wealthy are making provision for the just enjoyment of their blessings, nothing will more enhance their pleasure than the feeling of having helped to put a change of air and a generous diet within reach of one who has been shattered with illness.

BRITISH MEDICAL ASSOCIATION.

THE forty-eighth annual meeting of the British Medical Association commences on Tuesday next, at Cambridge. The president elect is Professor Humphry, and the addresses in medicine, surgery, and physiology are to be delivered respectively by Dr. Bradbury, Mr. Timothy Holmes, and Professor Michael Foster. We may anticipate a valuable address from Dr. Foster. The officers of the various sections have been wisely selected, the presidents being Dr. Paget, Mr. Savory, Dr. Playfair, Dr. Acland, Dr. Crichton Browne, Dr. Rutherford, Sir James Paget, and Mr. Bowman. Mr. Lister is to open a discussion on the treatment of wounds, and Sir Henry Thompson is to introduce the subject of stricture of the urethra. Hysterical anaesthesia, asthma, uterine haemostatics, the removal of uterine tumours by abdominal section, the general working of the Public Health administration in Great Britain and Ireland, the diseases communicable to man from diseased animals when used as food, the influence of alcohol on the causation of insanity, the formation of urea in the body, sleep, hypnotism, the influence of injuries and morbid conditions of the nervous system on nutrition, the relation of micro-organisms to disease, and the nature of glaucoma are other subjects to be specially discussed in the various sections; some of them at any rate, are sufficiently well-worn, if not threadbare. There will also be the usual festivities which are the special feature of these annual gatherings, and as Cambridge has so many attractions, and is within easy reach of London, we may expect a large attendance of members.

DANGEROUS TOYS.

A PLENTIFUL and cheap supply of toys will, it is generally considered, contribute to the happiness of children and the tranquillity of their parents. The recent action of the authorities in Paris suggests, however, that this result may not always be ensured. A toy producing the symptoms of lead-poisoning is not so conducive to the diversion of children and the peace of their parents as the Parisian itinerant vendor of these wares would have us believe. A number of boxes, loaded with toys, painted in brilliant colours, elastic balls coloured and varnished, lead soldiers in every variety of uniform, have been seized by the French police. It has been proved that the colour would easily come off, particularly if the children put the toys to their mouths, a habit which seems inherent in every child's nature. These playthings, painted with poisonous colours, had been imported from Fürth, in Bavaria, and a committee of the manufacturers of that town have recently held a meeting on this subject. A circular was at once issued to all the toy manufacturers, urging them to use non-poisonous paints, and reminding them that according to the German law they had exposed themselves to penalties—fines and imprisonment. The *Gesundheit* of Frankfort justly remarks that but for the repressive measures adopted in Paris the German authorities would still neglect to enforce the German law. This apathy, according to the German papers, is all the more reprehensible as the Fürth manufacturers send their toys all over Germany, and may therefore poison

the children of the fatherland as well as the little Parisians—a consideration which, in the Teutonic mind, must greatly accentuate the gravity of the question. To us the matter is not less serious. It is well known that the majority—in fact, nearly all—of the cheap toys sold in England are imported from Germany, and we regret that it is to the Parisians rather than to the English authorities that we must attribute the honour of seizing these dangerous playthings. We trust that no time will be lost in following this excellent example, and that a more strict watch will be kept to prevent the importation from abroad of poison for the nursery.

PATHOLOGICAL SOCIETY OF LONDON.

A "LIST OF DESIDERATA," drawn up by the Council of the Pathological Society, has just been printed and circulated among the members. It is issued in the belief "that it may prove useful in guiding the work of the Society. It is not intended in the least to restrict the spontaneous action of members, or to limit its scope." "The Council desires to gain for certain subjects that kind of elucidation which can be secured only by the abundant production of carefully examined facts." The plan of showing certain specimens "by card," which worked well last session, is to be continued, and the Council suggest "that, as a rule, any specimens exhibited simply in proof or illustration of a definite statement may be shown by card, whilst those which are more doubtful, which require explanation, and concerning the real nature of which differences of opinion may arise, had better be brought before the meeting *viva voce*." The "List of Desiderata" will probably be revised and reissued annually, and the Council will be glad to receive suggestions concerning it. The present list is a long one, and is evidence of the vastness of the field of pathology still unexplored.

THE MICROSCOPIC EXAMINATION OF WATER.

THE chemical examination of water leaves, as is well known, much to be desired from a sanitary point of view. It informs us of the condition with which organisms may be associated, but gives no information as to the presence of organisms. The microscope, as at present used, reveals only the coarser forms of animal life, and those only with uncertainty. M. Certes has endeavoured to ascertain how far it can be made to yield information of more direct value. The discovery of the microscopic organisms has hitherto been very much a matter of chance. Patience and skill are even of slight help. Fortunately, however, certain chemical reagents kill these organisms without changing their appearance; osmic acid is of especial value for this purpose. Once destroyed, they sink to the bottom, and, if enough of the liquid has been employed, they may thus be collected in appreciable quantity. The value of this method is shown by the following experiment:—If a test tube be broken, and the water it contained is contaminated by dipping in it the extremity of a rod which has been placed in an infusorial liquid, and it is then treated with osmic acid, the organisms will be found intact, and with readiness, by the aid of the microscope.

In the examination of water M. Certes employs a one and a half per cent. solution of osmic acid. One cubic centimetre of this solution will suffice for thirty or forty cubic centimetres of water, all animal and vegetable organisms being by it rapidly killed and fixed. In a few minutes, in order to lessen the blackening action of the osmic acid, as much pure water, as the test tube will hold, is added. In certain waters rich in organisms the microscopical examination may be made in a few hours. If the water is comparatively pure, twenty-four or forty-eight hours must be allowed to pass. The liquid, with the exception of the last one or two

centimetres, may then be decanted. The detection of the organisms in the residue is facilitated by the employment of colouring agents, such as Ranvier's picrocarminate, methyl violet, logwood, &c. It is always well to introduce the colouring agent mixed with glycerine; the organisms are thus better tinted, and can, if desired, be better preserved.

THE BIRMINGHAM AND MIDLAND EYE HOSPITAL.

THE annual meeting of this institution was held on July 24th, when the medical report was read by Mr. E. Chesshire, the Senior Surgeon. It showed that the number of patients was upwards of 1000 more than during the preceding year. The Chairman, Mr. W. S. Dugdale, adverted to the increasing popularity and usefulness of the charity, and urged on the governors the desirability of a speedy reconstruction and extension of the present building, as it was far from equal to the present demands on its accommodation. Others followed in the same strain, and it was ultimately resolved that immediate steps should be taken to carry the Chairman's suggestions into effect. The opposition on the part of the Town Council to the further use as a hospital of the present building, was not mooted at the annual meeting. The general opinion of the governors present seemed to be in favour of utilising the present building exclusively for in-patients, after rendering it in every way suitable to the modern requirements of an Ophthalmic Hospital, and to provide elsewhere a commodious out-patient department.

MEDICAL COLLEGES IN INDIA.

THE total number of students entered at the Calcutta Medical College at the commencement of the session inaugurated on June 15th last was 277, against 299 and 281 in the two previous years. The falling off in number has been attributed in great part to the elevation of the standard of preliminary education and the removal of the secondary classes. The Madras Medical College, on the other hand, appears to have experienced a season of increased prosperity during the year ending June 30th, 1880, the day on which the distribution of prizes, &c., took place. The report read by Dr. King, Principal of the College, showed that at the beginning of the forty-fourth session the names of 228 students were on the books, being 44 more than in the previous session, 47 of the total number being new entries. A corresponding increase in the strength of the teaching staff was considered necessary. The cost of the establishment had been 43,330 rupees, towards which 5920 rupees were contributed as students' fees. Surgeon-General Cornish, who presided on the occasion referred to, in the course of his address announced his intention of offering an annual prize of 100 rupees for the best reports of surgical cases treated in the Madras General Hospital.

THE CASE OF MR. BUNCOMBE.

MR. BUNCOMBE, medical officer of the Infirmary of the City of London Union, surrendered at the Central Criminal Court on August 3rd to take his trial upon a coroner's inquisition of a charge of manslaughter, arising from the murder of an inmate of the infirmary by David Salewskal, a Russian, who was insane. Mr. Poland, with whom was Mr. Montagu Williams, appeared for the Public Prosecutor, and stated that it was found there really was no evidence to support the charge, and that he had come to the conclusion that no bill should be preferred. Mr. Justice Hawkins concurred in this course being taken. He said it was clear that the coroner's inquisition could not be supported, made strong remarks upon the informal manner in which Mr. Buncombe had been sent before the court, and expressed his opinion that no imputation rested upon him, but that his conduct had been most kind and considerate.

DEATH CERTIFICATION BY MIDWIVES.

MR. HUMPHREY commented strongly lately on the circumstances attending the death of an illegitimate child, which died an hour and a half after its birth, but was certified by the midwife to have been *stillborn*. A medical man was called in after death, but, of course, could not certify. He communicated with the coroner, who very properly issued his warrant for an inquest. But his inquiry was forestalled and frustrated by the easy method of the midwife certifying that the child was stillborn. It is very wrong that midwives should have the power of certifying even to *stillbirth*. But it shows great carelessness on the part of the parish authorities to have buried in such a case as this. The midwife even was not present to explain the case and her conduct—viz., the certifying of a child as stillborn which had lived an hour and a half,—which seems worthy of the attention of the Registrar-General. The coroner should have applied to the Home Secretary to order the exhumation of the body.

DEATH OF BRIGADE-SURGEON W. R. STEUART.

WE regret to announce the death, on the 26th ult., at Dover, of Brigade-Surgeon William Ramsay Steuart, of the Army Medical Department. Mr. Steuart was gazetted an assistant-surgeon in August, 1854, shortly after which he was ordered to the Crimea, where he remained till the fall of Sebastopol, receiving for his services the war medal and clasp, and the Turkish medal. He was promoted surgeon on March 9th, 1867; surgeon-major in August, 1874; and was one of the officers selected by the Director-General for the new rank of brigade-surgeon a few months ago. Mr. Steuart's death was extremely sudden, and was due to apoplexy. He leaves a widow, but no children, to lament his loss.

THE VACCINATION BILL.

THOUGH this Bill is not yet formally withdrawn, the opinion prevails that there is no chance of its being proceeded with this session.

THE dinner of the Edinburgh Graduates' Club was held on the evening of Monday, the 2nd inst. (capping day), at St. James's Hall, Piccadilly; Dr. James Grey Glover in the chair. The attendance was good, and included the Rev. Dr. Allon and Col. Arthur, Dr. John Muir, Dr. Mortimer-Granville, Dr. Smiles, Dr. Holman, Dr. George Harley, &c., &c. A very interesting series of speeches were delivered by the chairman and others. In the course of his remarks on the subject of medical education in Edinburgh, Dr. Glover communicated the statistics showing the large national and imperial work done by the university. During the proceedings a congratulatory telegram from Professor Rutherford was read.

THE falling off in the funds of the Metropolitan Drinking Fountains Association, as announced in the report of the institution, is greatly to be regretted. Few enterprises have contributed more to the health and comfort of man and beast in the metropolis than the one which has supplied the thirsty traveller and the jaded animal with a refreshing draught; and we trust the means at the disposal of the Association will not be suffered to remain below the requirements of the benevolent object held in view.

It is stated that Mr. Lister, F.R.S., has declined to be put in nomination as a member of the Board of Examiners in the vacancy occasioned by the retirement of Mr. F. Le Gros Clark, and that in all probability Mr. Christopher Heath, a member of the Board of Examiners, will be elected, in which case he will resign his seat at the Board.

THE Government of France have placed 50,000 francs at the disposal of M. Pasteur in aid of his researches on contagious diseases of animals.

MR. AUGUSTUS PREVOST has been appointed treasurer of University College Hospital in succession to the late Mr. Edward Enfield.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sturminster Rural Sanitary District (estimated population, 11,208).—Mr. J. Comyn Leach's report for this district for 1879, as the report for the year before, 1878, is of so favourable a character as, to use his own phrase, to be "uninteresting from a sanitary point of view." We are disposed to cavil at the phrase, and to take more interest in reports that give indications of steady amendment in the health of a locality than in reports that are characterised by illustrations, usually fatal, of the mischievous effects of unhealthy conditions. It is desirable that sanitary authorities should learn that uneventful reports are the reports most to be coveted, as setting forth the goodness of their own efforts and the efforts of their officials. *Sturminster (Rural)* had in 1879 a birth-rate of 24·7 per 1000 population, and a death-rate of 15·7—the lowest death-rate observed since the organisation of the district under the Public Health Act, 1872. The lowered death-rate was particularly observed among infants, and as this was not to be accounted for by an exceptionally small mortality from diarrhoea, Mr. Leach hopes that the instructions to parents for the better management and feeding of infants issued by the Authority may be considered to have been a not unimportant factor in bringing about this result. Consumption appears to have been the most conspicuous of the causes of death in the district during the year, and Mr. Leach takes occasion of this to point out the influence of damp dwellings, unwholesome surroundings, and overcrowding, in fostering disease, and to urge the necessity of improved drainage, ventilation of dwellings, and increased cottage accommodation in the district. Two deaths from diarrhoea (in both instances in conjunction with other ailments), and one from whooping-cough, were alone registered as arising from the miasmatic order of zymotic diseases.

St. Asaph Rural Sanitary Authority.—Dr. J. Lloyd-Roberts has to report for this district for 1879 a general mortality differing little from that of 1878. There was some increase of the mortality of infants and children under five years of age, chiefly arising from the prevalence of scarlet fever and whooping-cough. Much sanitary work has been done in St. Asaph, and indications are given of sanitary work in progress and contemplated in other parts of the district. The following observations deserve attention:—"Generally the class of nuisances which have now become prominent by the removal of the more gross ones which were found when the sanitary authority came into existence are those which arise from accumulations in farm-yards and of house-refuse. In a district peculiarly agricultural the former accumulations are to a certain extent a necessity, and can scarcely be brought within regulations to limit them. On farms in many instances the position of the manure heaps might be changed without inconvenience to the farmer, and, with care in storing, their condition and influences might be ameliorated. In villages certainly some method might be introduced by which more frequent removals of night-soil might be effected. Thus ash-closets might replace the common privy; and in effecting a contract with neighbouring farmers to undertake the periodical scavenging of such places, the convenience of such a system of scavenging would be appreciated in many populous places in the district."

LIBEL ON A MEDICAL OFFICER OF HEALTH.

At the Manchester Midsummer Assizes an action was tried before Lord Justice Bramwell, in which the plaintiff

was Mr. J. Makinson Fox, the Medical Officer of Health for the Mid-Cheshire combination of sanitary authorities. The object of the action was to recover damages for the publication of an alleged libel upon the character and conduct of the plaintiff, as medical officer of health. The defendant was a resident of Lynn, and former member of the Lynn Sanitary Authority, and he had published in the *Warrington and Mid-Cheshire Examiner* a severe, and, as it was alleged, libellous criticism on the conduct and judgment of the plaintiff, in dealing with an outbreak of scarlet fever, using the words, "I ask, would not such conduct, under such circumstances, look something like insanity?" And if the children died, as in the case of the —, one after another, till the whole family of five were swept away, should not such a doctor as we have been supposing be justly regarded in the public opinion of the district as morally responsible for the consequences?" These were the words complained of; and the jury found that they were not a fair and temperate criticism. The Court thereupon gave judgment for the plaintiff, with costs.

Colonel Bolton, in his report on the water delivered by the metropolitan companies during the month, states that that derived from the Thames was generally free from turbidity, as also the water from the Lea, previous to filtration. He states also that the filtration of the several companies was "generally efficient," and adds some observations on the want of a duly authorised and official "standard of filtration." This is an old complaint, but hitherto the companies have evaded any standard of the "effectual filtration" the Act of 1852 requires, and the Government and metropolitan public have connived at the evasion. The chemical qualities of the Thames and Lea waters were fairly good throughout the month, and the deep well water of the Kent Company maintained its usual good character. All the companies are still extending the area of constant supply in their districts.

At the Southwark Police-court the magistrate has inflicted a fine of 20s. and costs upon a woman for having exposed herself in public, by pacing the streets and entering several public-houses, when she had the eruption of small-pox out upon her, and refusing to be taken to a hospital. The case was eventually removed to hospital under a magistrate's order, and the woman when she had been discharged recovered was prosecuted for the exposure. The defendant pleaded ignorance of the nature of the disease and distress in consequence of the loss of a child from small-pox. The plea of ignorance was shown to be inaccurate; the distress was held to be sufficient reason for not requiring the immediate payment of the penalty.

A curious case of nuisance is reported as having been before the Hertford Borough Bench. The nuisance complained of was caused by the offensive effluvia from a pipe used to ventilate the drains of a house, and apparently the sewer with which they communicated. The nuisance was ordered to be abated, but not a word appears to have been said about the state of the drains and sewers out of which the nuisance must have arisen; and it is by no means clear from the case as reported that the nuisance was not in reality caused by defective attention of the Sanitary Authority to the state of its sewers.

The managers of the Small-pox Hospital, Stockwell, have more than once been placed in serious difficulty by the failure of the water supply, which is derived from the mains of the Southwark and Vauxhall Water Company. A recent failure of the supply formed the subject of a discussion at the last meeting of the Metropolitan Asylum District Board, and it was decided to appeal to the Home Secretary on the subject.

Dr. Cameron and others have introduced into the House of Commons a Bill for amending the Public Health (Scotland) Act, 1867, and the Amending Act of 1879, with regard to the special rating of lands and premises where part only of a burgh or town falls within the district of a parochial board as local authority; and with regard also to the alteration or combination of special drainage and water-supply districts.

A butcher in Exeter has been sentenced to six weeks' imprisonment with hard labour for sending unwholesome meat to the London markets. He had been convicted three times before for a similar offence. A grain-merchant of Cocker-mouth has also been fined for having had the carcase of a cow unfit for food dressed for sale, and the butcher who dressed it has been fined £2.

A report recently made to the Barnsley Board of Guardians on the consumption of stimulants in the workhouse shows that the quantity of spirits consumed last year was less by £50 in money value than in the previous year. Milk, it is stated, has been substituted in great measure for stimulants, much, it is added, to the benefit of the inmates, the death-rate having been lowered. This seems a premature deduction from so short an experience in a small community. An inquiry is to be made into the supply of spirits to out-door patients.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Infantile summer diarrhoea was still more fatal last week, and caused a further increase in the rate of urban mortality. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5174 births and 3353 deaths were registered last week. The births were 11 below, whereas the deaths exceeded by 78, the average weekly numbers during 1879. The deaths showed a further increase of no less than 398 upon the numbers returned in recent weeks. The annual death-rate per 1000, which had been but 19·2, 20·1, and 20·6 in the three preceding weeks, further rose last week to 23·3. During the past four weeks of the current quarter the death-rate in these twenty towns has averaged 21·4 per 1000, against 24·3 and 17·6 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 15·1 in Sheffield, 15·2 in Bristol, 15·6 in Bradford, and 19·5 in Nottingham. The rates in the other towns ranged upwards to 24·6 in Manchester, 24·9 in London, 28·3 in Liverpool, and 33·5 in Brighton. The high death-rates in the three last-mentioned towns were mainly due to excessive zymotic fatality, more particularly of infantile diarrhoea.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 636 in the seven preceding weeks, further rose last week to 884. These included 577 from diarrhoea, 133 from scarlet fever, 65 from whooping-cough, and 66 from measles. The annual death-rate from these seven diseases averaged 6·1 per 1000 in the twenty towns; while it was but 0·8 and 1·7 in Bradford and Newcastle-on-Tyne, it ranged upwards to 10·9 and 13·6 in Norwich and Brighton. Scarlet fever was proportionally most fatal in Norwich and Salford, and whooping-cough caused the highest death-rate in Liverpool. Two more deaths were referred to diphtheria in Leicester. Small-pox caused 4 deaths in London (against 3 in each of the two preceding weeks), but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 200 and 198 at the end of the two preceding weeks, had further declined to 178 on Saturday last; 16 new cases of small-pox were admitted to these hospitals during the week, against 13 and 22 in the two previous weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which in the six preceding weeks had steadily increased from 51 to 337, further rose last week to 577, of which 350 occurred in London. The annual death-rate from diarrhoea averaged 4·0 per 1000 in the twenty towns; it was equal to 5·0 in London, but did not exceed 3·1 in the nineteen provincial towns. The death-rates from diarrhoea among these towns ranged from 0·5 in Bradford, and 1·2 in Sheffield and Bristol, to 5·3 and 10·2 respectively in Salford and Brighton.

The deaths referred to diseases of the respiratory organs in London, which had been 176 and 161 in the two preceding weeks, rose again last week to 200, and exceeded the corrected weekly average by 42. The annual death-rate from diseases of this class was equal to 2·8 per 1000 in London; it was 3·7 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate, which had been 18·6 and 20·6 per 1000 in the two preceding weeks, declined to 18·4 last week, and was 4·9 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 16·1 and 16·5 in Aberdeen and Edinburgh, to 23·4 and 24·9 in Paisley and Greenock. The fatal cases of

the seven principal zymotic diseases in the eight towns were 117, against 109 and 107 in the two preceding weeks; they included 55 from diarrhoea, 24 from whooping-cough, 11 from scarlet fever, 13 from fever (mainly enteric), 8 from measles, and 6 from diphtheria. The annual death-rate from these seven diseases averaged 4·7 per 1000 in the eight towns, against 6·2 in the large English towns. The zymotic death-rate in the Scotch towns ranged upwards from 3·0 in Aberdeen, to 7·8 in Perth and 8·5 in Greenock; the high rates in the two last-mentioned towns were mainly due to diarrhoea. The fatal cases of diarrhoea in the eight towns further rose last week to 59, against 39 in the previous week; the annual death-rate from this disease, however, did not average more than 2·2 per 1000, whereas the rate in the English towns averaged 4·0. The highest death-rates from diarrhoea in the Scotch towns were 5·9 and 6·6 in Perth and Greenock. Seven of the 8 fatal cases of measles were returned in Glasgow; and 13 of the 24 of whooping-cough occurred in the same town. The 13 deaths referred to fever exceeded the number in recent weeks, and included 8 in Glasgow, and 3 in Edinburgh. The deaths referred to acute diseases of the respiratory organs (bronchitis, pleurisy, and pneumonia) in the eight Scotch towns were 59 last week, against 58 and 69 in the two preceding weeks; the annual death-rate from these diseases was equal to 2·4 per 1000, against 2·5 in London. The causes of 112, or 25 per cent., of the 456 deaths registered in the Scotch towns last week were uncertified; in the English towns the proportion of uncertified deaths was only 2 per cent.

HEALTH OF DUBLIN.

The death-rate in Dublin showed a further decline last week, and was equal to 28·2 per 1000, against rates declining steadily from 42·5 to 30·2 in the seven preceding weeks. The death-rate in the city last week was lower than that which has prevailed for many months. During the past four weeks, however, the death-rate has averaged 30·0 per 1000 against 21·4 in London, and 17·9 in Edinburgh. The 170 deaths in Dublin included 35, or nearly 21 per cent., which were referred to the seven principal zymotic diseases, against numbers declining from 53 to 42 in the four preceding weeks; 7 resulted from small-pox, 7 from whooping-cough, 6 from fever (including typhus and typhoid), 6 from measles, 5 from diarrhoea, and 4 from scarlet fever. The annual death-rate from these seven diseases was equal to 5·8 per 1000 in Dublin, against 7·4 in London and 4·3 in Edinburgh. The seven fatal cases of small-pox showed a further decline from recent weekly numbers, and those of scarlet fever showed a marked decrease. The fatality of diarrhoea does not show the increase in Dublin which has occurred in recent weeks in the large English towns, the deaths of infants under one year of age, however, considerably exceeded the numbers in recent weeks.

WEATHER AND SUMMER DIARRHOEA FATALITY.

The rapid increase in the fatality of infantile summer diarrhoea in recent weeks, more especially in London, is the more remarkable when considered with reference to the meteorological conditions of the past month. The mean temperature of July was 61·7 at the Royal Observatory, Greenwich, and was almost identical with the mean temperature of the corresponding month in 100 years. The temperature of the month was, therefore, moderate; it was below the average on each of the first thirteen days, while it showed a slight excess on twelve of the last eighteen days. The weather was, moreover, unusually wet, even for July, and rain was measured on twenty-four of the thirty-one days to the aggregate amount of 3·8 inches, exceeding by 1·2 inches the average July rainfall in sixty-one years. The nearest approach to so large and frequent a rainfall in July during the present decade was in 1879, when 3·7 inches were measured on nineteen days. With moderate temperature and frequent and abundant rainfall throughout the greater part of July, the excessive fatality of diarrhoea during the past four weeks is the more noteworthy. In London no less than 810 deaths were referred to diarrhoea during the four weeks ending last Saturday, against 1167 and 94 in the corresponding periods of 1878 and 1879. In July, 1879, when the fatality of diarrhoea was so exceptionally slight, the mean temperature was remarkably low, while the rainfall was almost as large as it was last month, measured on almost as many days. Diarrhoea fatality generally

occurs rather earlier in London than in the provincial towns. During the past four weeks the annual death-rate from the disease has averaged 2·9 per 1000 in London, whereas in the nineteen large provincial towns it has not averaged more than 1·8 per 1000.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE DANGER OF MILK FROM PHTHISICAL COWS.

Dr. Vallin, in the *Revue d'Hygiène*, briefly referring to recent contributions on this subject, including the writings of Fleming, and especially Dr. Creighton's recent paper in THE LANCET on an infective variety of tuberculosis in man identical with bovine tuberculosis, urges the attention of scientific bodies to the subject. These bodies, he says, have at different times instituted Commissions for the study of cow-pox, rabies, glanders, &c.; should they not institute a Commission for an investigation such as this? He especially urges the question upon the attention of the Institute or the Academy of Medicine. Here is a subject which specially concerns the medical department of the Local Government Board, and which we should be glad to see included in the scientific medical research carried on by that department in continuation of Dr. Burdon Sanderson's investigations, made for the department, on the inoculation and development of tuberculosis. Meanwhile, asks Dr. Vallin, pending the experimental determination of the question at issue, is it not a matter of common prudence, in giving milk of which the source is doubtful to infants and invalids, that it should first be thoroughly boiled? Unless we are mistaken, it has been alleged that boiling does not offer a sufficient protection!

PREVENTION OF SPREAD OF INFECTION.

In the recent report of the Royal Commissioners on the sanitary condition of Dublin, the Commissioners state that, although it did not come within the limits of their instructions to report upon the imperfection of existing arrangements for the removal of sick persons suffering from infectious diseases to hospital, the disinfection of their dwellings, and the provision of temporary accommodation for their families during such processes of disinfection, yet these points deserve, they submit, the careful consideration of the Corporation as being the responsible sanitary authority. They suggest that it would be desirable to afford legal power to all sanitary authorities to make chargeable upon the funds at their disposal for the purposes of the Public Health (Ireland) Act, 1878, the expenditure necessary to provide temporary refuges for the reception of families who may be compelled to leave their infected dwellings during the progress of disinfection. Further, with the view of overcoming the objections of the poor to early removal to hospital for the treatment of dangerous infectious disease, they suggest that it would be desirable that in such institutions a ward for each sex be set apart as an "observation ward," into which all cases of a doubtful character should be admitted, where they could be retained and treated until the further progress of the symptoms had indicated the proper course to pursue with respect to them.

MILITARY OPHTHALMOLOGY IN RUSSIA.

Among other instances of the special attention which is now being devoted to ophthalmic medicine in the Russian army, it is reported that the "oculist" of the Kiev military circumscription, having recently visited the troops forming the garrison of that city, found many soldiers suffering from ophthalmia. He attributed this to the unwholesome hygienic conditions of the barracks and to the action of the sands surrounding the place. He has recommended the removal of the affected soldiers from the city, and it has been resolved in consequence to establish a special hospital for them on a healthy site on the banks of the Dnieper.

A TAX ON PRIVIES AND SEWERS.

The *Bombay Gazette* reports that Mr. Crawford, the second Assistant Collector, and Vice-president of the Municipality of Dholka, Ahmedabad, has issued a notice imposing taxes on houses, *privies, and sewers*. Eight of the unofficial members of the municipality having in vain protested against this taxation on the ground that the people were too poor to bear the burden, have tendered their resignations,

and memorialised the Governor of Bombay on the subject. The taxation of privies and sewers is a novelty to us, and indicates curious views of political economy on the part of the promoters. We could understand a public grant of money for the purpose of encouraging persons to construct privies and sewers, but privies and sewers as a source of revenue is a form of taxation which must be classed with that barbarous form of which we had an example here in the window-tax.

HOW CONTAGIOUS DISEASES ARE SPREAD.

At Drumcondra Petty Sessions, last week, Patrick Soey was summoned by the Guardians of the North Dublin Union, under the Public Health (Ireland) Act, 1878, for having on the 3rd of July, while suffering from small-pox, exposed himself to the public without taking any precaution to prevent the disease spreading. The defendant, it appeared, had gone about before he was properly recovered, although frequently cautioned by the medical officer of the Union, who attended him. The Bench, considering the case had been fully proved, fined him in the mitigated penalty of £3, Soey having pleaded ignorance of the consequences of his act.

The number of cases of fever in Swinford Union has decreased considerably of late, and no death has been recorded since the 17th ult. Up to last Saturday, the 31st ult., there were sixteen cases of typhus in the entire Union, and only eight cases in the fever hospital.

The Poplar Board of Guardians have agreed to a suggestion made by the Asylums Board, that the ambulances employed for the conveyance of persons suffering from infectious disease should be disinfected at the several hospitals at which the patients had been received.

During the week ending the 10th July, 675 deaths (404 males and 271 females) were registered in St. Petersburg. The greatest number of deaths were assigned to "typhus" and phthisis.

THE VACCINATION ACTS AMENDMENT BILL

ON Monday, the 2nd inst., a deputation, consisting of Mr. Spottiswoode (President of the Royal Society), Dr. Risdon Bennett (President of the College of Physicians), Mr. Erichsen (President of the College of Surgeons), Mr. Spencer Wells (Vice-president of the College of Surgeons), Dr. Erasmus Wilson, Professor Huxley, Dr. Farquharson, M.P., Dr. Pitman, Dr. Quain, Dr. Russell Reynolds, and Dr. Wilson Fox, had an interview with Mr. Dodson, at the Local Government Board Offices, to urge their views on this Bill.

DR. RISDON BENNETT said,—It would be perhaps right that I should, in the first place, explain what may seem rather wanting in respect towards you in connexion with this matter; but the fact is that when you were good enough to give me your courteous reception before, it was with the view of my ascertaining the opinion of the College on this Bill, and having done so they expressed so strong a feeling upon the subject that it was determined to ask from you an informal reception on behalf of the College at large, and so it is that we are here a second time. We have looked again into this Bill with care, and the result was, the drafting of the petition which, I believe, has been presented to the House of Commons, and which contains, in a summary form, the views of the College of Physicians on the subject. The law as it stands seems to us to be acting most beneficially, and to be doing much towards diminishing the spread of small-pox; so that if it is continued in its present force, with a little more attention to the efficiency with which vaccination is performed, there is good reason for believing that practically—I do not say absolutely—small-pox will be exterminated from this country. Now, the Bill as it stands openly says to the public, "You may either be vaccinated or pay the fine;" and if you pay this fine you are at liberty to communicate to the public this disease, which has been attended with such frightful consequences in bygone times." The answer to that, as I understand, is, that the law as it stands leaves a certain number

of children unvaccinated, who are consequently sources of danger. That is true; but it does not say to the world at large, as this Bill does, that these children may continue to be unvaccinated, and that it is matter of little consequence to the public whether they do it or not, and that it is a matter of free choice and you can do it if you like. We feel that it is of very serious moment for any number of children to remain unvaccinated; because, although a very large portion of the community are protected, they are only protected to a certain extent. Nobody maintains that vaccination is an absolute protection after the expiration of a certain number of years against the taking of small-pox, because the complaint is only as a rule taken once. There are many instances where it is taken a second time from peculiarity of constitution, climatic influences, and so on; and although we are prepared to advocate the efficiency of vaccination as a protection, we do not say that you may not, after a certain time, become susceptible to it; and we say that these unvaccinated children would subject persons so susceptible to the disease. It seems rather late in the day to say anything broadly and simply in the matter of vaccination. Then with reference to the objection of some of the anti-vaccinators to the law as it stands, that it introduces other diseases which are at the same time attended with fatal consequences; there are sufficient answers to be given to that; and with reference, for example, to certain cases of syphilis, which in some cases have followed vaccination, it does not follow that they have ensued where vaccination has been properly performed. There is no doubt that there are cases where disease has followed from vaccination, but not where the vaccination has been properly performed. Then with reference to erysipelas and other causes that occur after vaccination, the fact is that these things are occasioned by the most trifling causes in connexion with the state of the atmosphere, and have no relation to the vaccination. Then we also feel that it is very undesirable in a great measure of this sort, where the health of the community at large is so seriously concerned, that too much attention should be paid to the objections of a small party who, from various motives, but mainly, I apprehend, from sheer ignorance, raise these objections. We feel that when a consensus of opinion of a great profession like the medical profession is so decided upon the subject, and when the evidence before the public is so convincing, if it is looked into, that it is scarcely the thing for the Government to give way to a few objectors, or to give way on the plea that the thing is troublesome to carry out now and then. We can quite understand that the Local Government officers have troublesome people to deal with, and it may be annoying; but we think these are trifling things, which should not weigh with the Government interfering with the efficiency of a great measure like this.

MR. ERICHSEN said the College of Surgeons looked upon compulsory vaccination as absolutely necessary for the protection of the community and the maintenance of its health, and looked with regret on any measure that would in any way militate against vaccination becoming universal. If vaccination could be made universal in infancy, and were properly performed, small-pox would become a thing of the past. The law had to contend against ignorance of the evils attending the spread of small-pox. People of the present day only knew small-pox in the form modified by the beneficial influence of vaccination. There was no evidence that vaccination spread diseases provided it was carefully and properly performed. A careless surgeon might spread syphilis by the touch of his hands, or by using a dirty knife, by not wiping an instrument in going from one patient to another, and so, also, might a careless vaccinator spread disease. If he did he should be proceeded against for malpractice, and he would be punished, as he deserved to be. If a large number of children were to be left unvaccinated, as it was to be feared would be the case by payment of the fine, a considerable portion of the community might take advantage of the law, and thereby lead to the epidemic of small-pox becoming excessive among those children. In former days sevenths of the whole mortality from small-pox occurred in children under the age of puberty; and if vaccination were neglected the disease would spread itself in a far less modified form amongst those who were only partially protected by primary vaccination and who had not had the advantage of being revaccinated. Revaccination was a subject which might well engage the attention of Government hereafter.

MR. SPOTTISWOODE observed that the members of the

Royal Society concurred in condemning the Government Bill which was concerned with a subject so nearly relating to physiological science.

Professor HUXLEY said—The remarks which I would venture to offer to you are these: that the present moment is particularly inopportune, from a purely scientific point of view, for any action on the part of Government, which might be construed by ignorant persons into an admission that the evidence in favour of vaccination is in any way defective or weaker than it has formerly been. Of course, up to the present time, or, at least, six or seven months ago, the evidence in favour of vaccination, however satisfactory it might be to many persons, including myself, had not scientific completeness. The subjects of inquiry being human beings, you could not apply the scientific method in its fulness; but within the last six or seven months a very eminent French investigator, M. Pasteur, and some other French observers, have been applying an experimental method in all its rigour to certain epidemic diseases, and that which M. Pasteur has investigated is known as "chicken cholera." The disease to which he refers is excessively fatal. If it attacks a farmyard the general rule is that it kills all the fowls attacked. But in the most favourable cases a few (80 per cent.) recover. Those are his figures. M. Pasteur has determined the nature of the infection, and he finds he can cultivate and produce the disease artificially, and so forth. But the most remarkable part of his discovery is this—that, by treating the *matrices morbi* in a certain fashion, he can diminish its virulence; and by vaccinating fowls with it he can protect them from the influence of the disease. So that supposing you take forty fowls, and divide them into two parts of twenty each, and you give the one the undiluted poison, those twenty in all probability die; but if you carefully inoculate in the manner he indicates the other twenty fowls, as you submit them to exactly the same process as that which causes them to die, they either do not suffer at all, or, in the least favourable cases, 80 per cent. recover. So that we have here in the case of a serious epidemic conclusive evidence of a process precisely analogous to vaccination in protecting against the effects of infection. The experiments of splenic fever are as yet incomplete; and the results have not been published, but they tend in exactly the same direction, to show that sheep and dogs by being inoculated by the splenic fever poison in the particular form, they suffer a slight malady and are absolutely protected from the disease. This to us, in the presence of the first evidence, would be perfectly satisfactory to science in its first form, but so far as the evidence stands it is clear and perfectly demonstrative of the value of the process analogous to the process of vaccination. So that we are quite safe in extending the argument by analogy. We may say that we have for the first time got something like complete scientific evidence of the value of the process of vaccination.

Dr. FITMAN pointed out that the Bill seemed to give immunity to persons to break the law by the payment of a fine. If that principle were to be applied to every offence it would be a dangerous principle to introduce into the English law.

Dr. WILSON FOX reminded Mr. Dodson that the law did not allow one person to injure another from conscientious motives; and he quoted the case of the "peculiar" people, who would not call in medical aid, but depended on superstitious rites for saving life, and who had been charged with and convicted of manslaughter. A man left his child unvaccinated, and thereby endangered that child's life and the life of other people. It was criminal and an entire variation of the law to allow conscience, which was the only thing that could possibly be argued, to justify any departure from the present law. The law, if anything, ought to be made more stringent.

Mr. DONSON in replying said, "It appears to me that we have arrived at an understanding; that is to say, it is perfectly seen and understood now that the law as it stands is not directly compulsory, but simply inflicts a succession of fines for the omission to have a child vaccinated; and that what the Bill does is not, as has been said, to give a licence to violate the law or to exempt people from its operation; it is simply a question of mitigating penalties by reducing their number. There is no difference between us as regards the value of vaccination, and the desirability of making it, if possible, universal. The only question between us is as to the best mode of bringing it about, and upon that of course the opinion of the medical profession is exceedingly valuable. Sometimes it is a question of expediency and

policy upon which persons who wish to administer the law and to establish the law are perhaps as competent to form an opinion as the medical profession itself. At all events, it is one which, as must be seen, no one profession can claim to be able to form a judgment more particularly than another. Perhaps those who have to administer the law are, if any, those whose opinions would be the most valuable in such a matter as this. We have to deal, as it has been stated here—and I will assume for a moment that it is so—with a very small minority of persons who in the main belong to the more uneducated classes. We have to deal with men as we find them, and the question is, Which is the best way? Is the object best attained by this multiplication of fines, and giving men notoriety, and making martyrs of them at the expense perhaps of the Association that pays their fines; or will the object be better attained by avoiding giving this importance to certain individuals? That is entirely the point which introduces itself; and it is simply a question of expediency. It may be that it is exactly this multiplication of penalties that tends to foster and keep alive anti-vaccination leagues. It has been said "that the blood of martyrs is the seed of the Church," and that is the question in this case. The blood of these martyrs may not be the seed of the anti-vaccination case that keeps it alive, but it is a question of expediency. Well, I can only say that I am exceedingly glad to have seen this deputation to-day, and to find that we have come to understand each other much better, and that the only point of difference between us is this one of expediency. Upon that point I quite allow the medical profession is entitled to great weight, but I cannot admit that on such a question as that that it is entitled to outweigh other opinions, more especially the opinions of those who have to administer the law. By the way, it has been said that the Bill was a concession to agitation, and so forth; I can safely say that the Bill was no concession to any agitation whatever: the Bill was simply introduced with the view of giving effect to the recommendations of the Committee of 1879, which expressed the opinion that the multiplicity of penalties tended to keep alive an animus against the law; and I am not aware that the agitation has been particularly alive within the last few months more than it was before—I mean there has been no pressure brought to bear upon the Government.

The deputation thanked Mr. Dodson and retired.

THE PARKES MUSEUM.

WE were unable last week, owing to pressure upon our space, to give more than a brief notice of the meeting which was held at the Mansion House in connexion with the above Museum. Sir W. Jenner's remarks upon the occasion were, however, so forcible and so practical, and their importance is so great, that we give them here in a more extended form. Sir William Jenner said—

My Lord Mayor, Ladies, and Gentlemen,—You have heard some very eloquent addresses in support of this Museum. I wish to say a few words as to its origin. Dr. Parkes, whose name it bears, was one of the most amiable men that ever lived. I think he was the nearest to perfection that I have, in my long experience, been acquainted with. He was not only amiable, but he loved his race, and desired on all occasions to benefit others. He thought little of himself, and devoted the last years of his life to the study of hygiene and how it could be applied for the public good, and died deeply regretted by all who knew him. When he was dead the profession thought how they could best honour his memory—what memorial we could erect to so excellent, so good, so honourable, so great a man; and we thought of busts and pictures and various other modes of keeping alive, so long as those who knew him were here, his memory. We loved him too dearly to require to see his picture before us. We dismissed that, and then we thought of scholarships, thinking they would be of some service, but not much. There are a great many scholarships, and many of them of little service; and we did not see how they would accomplish what he, good man, would wish; and so it was determined to found a Museum for the purpose of spreading abroad the knowledge of those principles of hygiene to which Dr. Parkes had devoted the energies of his latter days. And so we joined together to found the Parkes Museum. I was elected Chairman of the Executive Committee, and hence I

am here especially this afternoon. Well, that was its origin. Now, it was determined to get together a collection of appliances, &c., which required to be explained, and it was determined that some of our friends should give lectures and expositions to the workingmen especially; others who pleased were to go, but the workingmen were invited with the view not only to the improvement of their own homes, but the homes of you who live in great houses also. Living in a great house does not keep a man safe from disease, and I will give you a case in point. I had a gentleman to see who was too ill to leave London and who has a great place of his own in the country. He was staying at an hotel, and had to be moved into a house suitable to his rank and station. Well, his wife looked round London for a house, and at last she found a great mansion, described to me as one of the finest mansions in London, situated in one of the finest regions in London, from which a noble earl was about to move out, and who consented to move a little earlier to make way for my friend. The medical man of the gentleman about to become the tenant said, "Let us see what is the sanitary state of the premises, and let us have a report from a competent authority." Many of you will not understand this allusion, for if you want to have your houses healthy you must support this institution in which the workmen employed will know how to make a house healthy. Many will not understand it, but those that do will see the importance of it. This report was only given a few days ago, and what did it say? Why, that in this, "one of the finest mansions in London, the waste pipes from the baths descend into the soil pipe unventilated." That is to say, that the sewer gas found its way right into every bath-room in the house. Now let us think what that is for a moment. The sewers of this metropolis are always filled with the poison of typhoid fever, of diphtheria, and a series of other terrible maladies, so that the persons living here were breathing these vapours, and it could only have been by accident that the inhabitants of the premises in question escaped infection. If they had inhaled them they would be suffering from some of these dreadful diseases. Medical men know only too well the fatal consequences of ignorance of the commonest forms of sanitary precaution. To-day they find a mother weeping for her child, to-morrow a wife lamenting the loss of her husband—and all through not knowing the first principles of sanitary science as applied to the houses in which they lived. Well, what else is found in "one of the finest mansions in London"? "The basement sinks, and all upstairs save one housemaid's sink, go into the drain direct; the closets are valve-closets in best part of house; but the closet-rooms are unventilated, except the second floor and top water-closet. The main cistern on the roof supplies a closet, and the basement drinking-cistern has its waste-pipe entering the drain." From this description you will see that there is nothing to prevent the drinking water of "one of the finest mansions in London" becoming charged with typhoid poison direct from the sewers, which must give typhoid fever. This shows you what some of the biggest houses are like. It is not intended to found a charity. We do not come here to plead for a charity, unless it be, and I think there is great truth in the saying, that "charity begins at home"; but it should not end there. It would commence there if you would support an institution like this, so that a true knowledge of sanitary science may be spread amongst the working classes; it would not end there if men who have been taught to save the lives of their own children will, by their skill in the construction of dwellings, enable others to do the same. Even if only one mother should save her child's life, do you not think it would be beginning charity at home? I have spoken of the terrible diseases which may arise from bad water, bad air, &c. That is a small part of what may be produced. The life of a man depends upon his blood. It is his blood that nourishes his brain and his body, and the quality of the future man depends to a very great extent upon the quality of the blood in the child. Now, it follows that a child who is constantly breathing foul air is deteriorating, for blood is the pabulum of life. Many a person who is suffering from out-of-healthiness is suffering from breathing perpetually foul air. Sore-throats and a variety of complaints owe their origin to this cause. The doctors see it, and tell you you are living where there is foul air. A parent asks, "Why, all my children are looking pale and miserable; they have a healthy situation, where they have baths, &c." But the explanation was simply that the sanitary arrangements were not perfect. I

will give you an instance that came under my own observation. Not long ago I went to Mortlake, where my children were at school, and I was told by the schoolmaster that a sewer was ventilated outside his door, and I gave the master a certificate that serious consequences might result, and I said, amongst other things, that perhaps you will have pneumonia. What happened? They would open this sewer, and the result was that a poor little page boy, whose window abutted on to the work which was being done, was seized with pneumonia. I ask you to educate these people. I paid a lot of money a little time ago that the drains of my house should be put into order, but after a month I found everything as bad as it could be, and I sent for another man and paid a lot more money; but they were not put right, and I sent a third time, and I had been recommended a sort of clerk to the works, a man who seemed very well educated. I happened to come home in the middle of the work, and the foreman pointed out to me that he had fixed a D-trap to a certain pipe, and I said I would not have a D-trap. He said it was a model thing. When I turned upon him, and said, "A D-trap; I call it a double D-trap, for it will deal out disease and death." D-traps always require inspecting. The fact was that these so-called intelligent workmen were desirous of doing what was right, but were ignorant how to do it. I went round the house, and found that the man had trapped the ventilating-pipe of the sewer, and the result would have been a burst of sewer-gas. If any of you want your drains or your water-supply put in order how are you to get it done? I am asked the question constantly; the workmen have never been taught, and you should go to those who have made these matters their study. These workmen are as conscientious in their work as you and I, but they are ignorant of sanitary principles, and ignorance deals out disease and death. I am sorry to detain you so long. What we want—I am chairman of the Executive Committee, and I am going to speak very plainly, as I usually do—is money to carry out our views, and to continue the work which we have begun. A good many years ago I was asked by a lady to visit her husband, who was desirous of giving away a large sum of money, much larger than she thought he could afford, and use my influence in the matter, and she said, perhaps you will accidentally drop in after church, and just bring up the subject; and so after church, where perhaps I had heard a good sermon, I mentioned the matter to him, and this is the remark he made when I referred to the largeness of the sum: "Yes, it may seem so to you who are a doctor, but it is nothing to City men." Now we come into the City and we want a large sum to found this institution. We have done what we could, and we doctors are animated solely by the desire to prevent people being ill. We are like the lawyers, who are animated by the desire to prevent people going to law, and we ask you to help this museum. Now that we have got the first citizen in the City of London, the largest city in the world, the richest city in the world, and most liberal city in the world, presiding on this occasion we hope that his name and the influence of him and others will be brought to bear to secure a habitation and all that is needful for advancing this good cause.

ARMY MEDICAL SCHOOL.

THE Summer Session of the Army Medical School at Netley terminated on Monday, the 2nd inst., when, after the preliminary business of winding up the Session had been concluded, the prizes at the disposal of the senate of the School were handed to the successful competitors, before a large assembly of officers and visitors, by Sir C. K. Pearson, K.C.M.G., C.B., of Ekowe reputation, now Governor of the Royal Victoria Hospital and Commandant of the Station of Netley. After delivering the prizes, Sir C. Pearson gave an interesting and lengthened address on the position and responsibilities of officers of the medical department in the different branches of the military services. Sir J. Fayer, K.C.S.I., and Mr. Macconnac, also addressed some appropriate remarks to the assembled probationers. The visitors then adjourned to the Army Medical Staff mess-room, where luncheon was served.

The following are the names of the successful surgeons on

probation for Her Majesty's Army, with the numbers of marks obtained by them. In the instances of these gentlemen the marks gained at Netley are not counted, and they retain the places taken by them in the competitive examination at London:—

	Marks.		Marks.
G. H. Sylvester ..	1925	E. L. Maunsell ..	1375
W. J. Macnamara ..	1900	J. S. Langdon ..	1350
D. O'Sullivan ..	1725	W. F. Heffernan ..	1345
E. O. Milward ..	1710	R. W. E. Nicholson ..	1345
P. B. Conolly ..	1660	J. G. W. Crofts ..	1330
C. R. Woods ..	1600	W. Dugdale ..	1325
H. F. Babington ..	1585	D. L. Irvine ..	1325
W. C. Milward ..	1575	J. Ronayne ..	1320
W. H. Bracken ..	1565	C. H. Clabburn ..	1290
M. F. Macnamara ..	1490	E. R. Cree ..	1275
J. O. Sandiford ..	1480	M. O'C. Drury ..	1260
R. L. Love ..	1465	W. Deane-Freeman ..	1245
H. W. Murray ..	1455	J. H. Nicholas ..	1200
M. W. Kerin ..	1420	D. F. Franklin ..	1175
A. Peterkin ..	1420	J. L. Curtin ..	1160
J. Harran ..	1405	H. Saunders ..	1155
W. S. Leckey ..	1395	J. Battersby ..	1150

The following is the list of candidates for commissions as Surgeons in Her Majesty's Indian Medical Service and Royal Navy in order of merit, and with the total number of marks gained by them at both the London and Netley examinations:

INDIAN MEDICAL SERVICE.

	Marks.		Marks.
*J. Simpson ..	5635	T. R. Macdonald ..	4094
†C. P. Lukis ..	5483	C. B. Maitland ..	4068
R. R. H. Whitwell ..	5465	D. F. Dymott ..	4018
L. A. Waddell ..	5283	R. H. Cama ..	3998
H. P. Dimmock ..	4530	W. B. Browning ..	3980
G. Shewan ..	4445	C. Henderson ..	3896
D. B. Spencer ..	4396	F. R. Divecha ..	3892
J. Clarke ..	4391	A. P. Adams ..	3864
C. C. Vaid ..	4388	C. M. Thompson ..	3783
P. D. Pank ..	4303	C. S. Rundle ..	3667
†C. F. Willis ..	4106	J. W. Evans ..	3612
T. R. Mulroney ..	4115	J. Leonard ..	3604

* Gained the Herbert Prize and the Martin Memorial Medal.

† Gained the Parkes Memorial Bronze Medal.

‡ This gentleman became ill last session.

	ROYAL NAVY.	Marks.
H. G. Jacob ..	..	4758
W. M. Lory ..	..	4266
W. S. Lightfoot ..	..	3644

ROYAL COLLEGE OF SURGEONS.

At an ordinary meeting of the Council of the College of Surgeons held on Thursday last, a letter was read from Sir James Paget, reporting the proceedings of the General Medical Council. Mr. Le Gros Clark's resignation from the Court of Examiners was received, and several nominations were made. The President announced the result of the interview with the Local Government Board respecting the proposed Vaccination Acts Amendment Bill.

HOEING BONE-GOUGE.

DR. HENRY MONCKTON, of Rugeley, desires to draw attention to a form of bone-gouge of which the accompanying woodcut is an illustration. He has used it several times, and believes it to be more handy and convenient than the straight, angular, or forcep gouges in common use. The

instrument is, in fact, the timber-scribe employed in marking trees, &c.; but it is found in surgical practice very efficient in rapidly cutting away sound bone beneath which a sequestrum is known to be buried. From inquiries made among

surgical instrument makers and dealers, Dr. Monckton has reason to think that bone-gouges having this reversed action have not hitherto been in the hands of surgeons. Should the idea be adopted, makers will doubtless improve upon the tool depicted above in the details of elegance and refinement. The actual cutting edge is shown at C.

THE SERVICES.

MEDICAL OFFICERS FOR INDIA.

IN view of the extended operations in Afghanistan a large reinforcement of medical officers has been placed under orders for immediate service in India. Surgeon-major S. E. Maunsell, with Surgeons Cowen and Clark, embarked at Portsmouth on Tuesday last in the *Orontes*. Surgeon-major Wade is detailed for medical charge of the troops leaving England on the 6th in H.M. Indian troopship *Euphrates*, with Surgeons Barker and Michael as assistants. Forty of the newly-joined surgeons who have completed the Netley course, and also undergone instruction in ambulance and stretcher drill at Aldershot, have been warned to hold themselves in readiness to embark for the East at short notice. The medical staff at the disposal of Surgeon-General Crawford will, on the arrival of these reinforcements, be ample, as it is probable that many medical officers who in the ordinary course would have been relieved this season will be detained in India till the Afghan War is ended, a termination which we hope to see before many months are past.

THE EXAMINATION FOR THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

The competitive examination for Commissions in the Medical Departments of the Army, Navy, and Indian Medical Service commences on Monday next, the 9th, at Burlington House. We understand that no less than eighty-six gentlemen have sent in their names for the Army, eight for the Navy, and thirty-five for the Indian Service. The unpopularity of the navy with the young members of the medical profession is not likely to be removed till a liberal and satisfactory Warrant is issued.

ADMIRALTY.—Staff-Surgeon Solomon Kellett has been appointed to the *Impregnable*, in lieu of a surgeon; Surgeon W. M. Rae to Bermuda Hospital; Fleet Surgeon T. R. Warren to Sheerness Dockyard; Surgeon W. S. Lightfoot to the *Duke of Wellington*, for Haslar Hospital; Surgeons G. Jacob and W. M. Lory to the *Royal Adelaide*, for Plymouth Hospital; and Surgeon E. W. Luther to the *Asia*.

The Standing Medical Boards at ports of embarkation have (says the *Indian Medical Gazette*) been abolished, so far as concerns officers of the Indian Services who have appeared before local boards.

Correspondence.

"Audi alteram partem."

THE CASE OF SWEETLAND.

To the Editor of THE LANCET.

SIR,—The case of the unfortunate Sweetland is additional evidence, if evidence were wanting, of the unsatisfactory state of the law with regard to insane homicides. I use the term "insane homicide" in preference to "criminal lunatic," for I fail to perceive how a man can be a criminal lunatic when the fact of insanity being proved absolves from all responsibility as to the particular act for which he is tried. The whole of the difficulty which surrounds these cases is to be found in the determined opposition of the law to medical science—a conservatism which has sent many an unfortunate lunatic to the gallows. It appears that some of the American judges are inclined to take a view of these cases of insane homicide more in accordance with the progress of modern science. I have before me while I write the charge

of Judge Doe, of New Hampshire, delivered in 1869. He says, "At present precedents require the jury to be instructed by experts in new medical theories, and by judges in old medical theories." In doing this "the legal profession were invading the province of medicine, and attempting to install old exploded medical theories in the place of facts established in the progress of scientific knowledge. That cannot be a fact in law which is not a fact in science; that cannot be health in law which is disease in fact; and it is unfortunate that courts should maintain a contest with science and the laws of nature upon a question of fact, which is within the province of science and outside the domain of law." He further remarks, "If the tests of insanity are matters of law, the practice of allowing experts to testify what they are should be discontinued; if they are matters of fact, the judge should no longer testify without being sworn as a witness, and showing himself qualified to testify as an expert." This, to my non-legal mind, seems to be good, sound common sense. If it were not admitted that there are certain facts with regard to insanity cognisable by medical men none of the persons found in our asylums ought to be there. The law in these cases admits that there are facts of insanity of which medical men are competent judges, but in criminal cases, for some reason not clearly defined, the law utterly repudiates medical testimony. In all other cases the testimony of experts is accepted and acted upon; why not, therefore, in the case of insanity? Another anomaly also present in these cases is this, the public are fully acquainted with the evidence that convicted Sweetland, but no one knows the grounds for the alteration of the sentence. The grounds for the reprieve should become as public as those for the conviction; and why should not the evidence on which the reprieve is granted have been allowed on the trial? Apologising for having taken up so much of your valuable space,

I am, Sir, yours faithfully,

H. AUBREY HUSBAND, M.B.,

Lecturer on Medical Jurisprudence, Edinburgh
School of Medicine.

July 12th, 1880.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—In so horrible a disease as cancer of the female genital organs, and one in which we are compelled to admit that we are powerless to do more than palliate suffering, I quite agree with your correspondent Mr. Hickinbotham (*vide THE LANCET* of June 19th), that it is our duty to adopt any treatment which is supported by high authority, and especially by so high an authority as Professor Clay. It is, I think, equally our duty to report the result of such treatment fairly and without prejudice, whatever those results may be, and I therefore briefly give you my notes of a case in which I have employed this remedy.

Mrs. H—, aged sixty-two, a widow, who has never borne children, complained to me in February of the present year of passing blood with the urine, pains in the back and legs, and great weakness. I thought her suffering from disease of kidneys and consequent hæmaturia, but on visiting her at home I found the urine perfectly clear, with one or two small coagula at the bottom of the vessel. I then made a vaginal examination, and found a cancerous growth, which bled freely on the slightest touch, extending from the back of the meatus upwards for about two inches in the anterior wall of the vagina; above this the wall appeared healthy, but somewhat hard and thickened; the os uteri was freely movable, and did not appear to be involved. Continuing under treatment she had occasional attacks of sharp hæmorrhage, which yielded to rest and astringent injections.

On the appearance of Professor Clay's article I thought this a typical case for treatment, and accordingly, having first examined her again, and found the disease slowly but steadily progressing, commenced the Chian turpentine in the form of emulsion as advised by Professor Clay, explaining to the patient that it was a new mode of treatment which had already produced highly successful results, and thus, by instilling great hope into her mind, securing her anxious co-operation with me in the treatment. She commenced taking the turpentine on April 18th, and continued it without the intermission of a single dose to June 20th, when it was discontinued. The effect at first appeared to be that of decidedly relieving the pain and enabling her to move about

with much more comfort, though whether this was due to renewed hope or the action of the remedy is a question. After a month's trial the medicine seemed to create some loathing, but she determined to persevere. She continued it till June 21st, when a severe attack of hæmorrhage compelled me to resort to other treatment, and at the request of her relatives Dr. Coates saw her with me on the 25th inst. The condition we then found was as follows:—The front of the vagina was converted into a solid hard mass, which had extended in all directions, contracting the passage considerably; the os uteri fixed and hard; the inguinal glands enlarged, and, in fact, a more rapid development of the disease than I was prepared to expect.

My conviction (with which I believe Dr. Coates fully coincides) is that this remedy had utterly failed either for good or evil to influence the course of the disease.

I have tried it in two other cases, one of epithelioma of the lip, the other of cancer of the pylorus, but in both cases without the slightest effect, but have preferred to publish the above case as being one in which no other treatment was used, and in which it was perseveringly and unintermittingly followed up.

I may add that the emulsion was dispensed by Messrs. Davies and Hughes, whose reputation as dispensing chemists ranks deservedly high in this city.

I remain, Sir, yours, &c.,

Green Park, Bath. ROBERT BIGGS, M.R.C.S.E., L.S.A.

To the Editor of THE LANCET.

SIR,—The two following cases have recently been treated by the above method:—

Case 1 was a woman, aged forty-eight, with cancer of womb of six months' duration. Dr. Clay's ethereal solution of turpentine with sulphur was used. Treatment commenced on April 17th, 1880, and continued to the present time; patient has gradually emaciated; pain unrelieved; disease has continued to advance, notwithstanding that the medicine has been well tolerated by the stomach. Case 2 was one of cancer of breast in a woman aged sixty-five. The breast had been totally destroyed by the disease—a large circular ulcer, with hard everted edges, situated where the breast had been. Treatment commenced same date as Case 1, and continued till patient's death, on July 3rd, 1880. Although the patient died in this instance, the base and edges of the ulcer became softer and the ulcer smaller in diameter. Although there was some affection of the axillary glands when the treatment was commenced it did not spread much. What the result would have been if treated earlier it is impossible to say.

I am, Sir, yours faithfully,

Workington, July 17th, 1880.

F. ORMROD.

EDINBURGH.

(From a Correspondent.)

AT the graduation ceremonial on Monday 158 medical candidates appeared for degrees; of these 28 received that of M.D.; 124 M.B. and C.M.; and 6 M.B. alone. The following gentlemen obtained gold medals for their theses, Drs. De Burgh Birch, Allan Gray, David Berry Hart, and J. Francis Sutherland. The Ettles Prize has been awarded to T. P. Anderson Stewart, who obtained the highest number of marks during the course of his professional examinations; the Beaney Prize to H. W. Dobie, who stood highest in Anatomy, Surgery, and Clinical Surgery; the Wightman Prize to R. F. Rand, for the best essay on clinical cases, and the Syme Surgical Fellowship to Dr. David Berry Hart. Mr. W. L. Goodwin obtained the Hope Prize in chemistry. Professor Turner introduced Dr. William Roberts, of Owens College, Manchester, to receive the Cameron Prize for his researches in the Digestive Ferments, &c. Professor Rutherford, in delivering the valedictory address took up the subject of Medical Examinations and Reform. He objected strongly to the English one-portal scheme, indicated the leading part played by Scottish Universities in medical education, and suggested that a few simple reforms would act more beneficially than certain proposed radical changes. Professor MacLagan presided at the Graduates' dinner in the evening.

Last week Mr. Spence had, as he anticipated, a very troublesome case of lithotomy. The patient was an adult with a somewhat narrow pelvis. All attempts to remove the stone by the ordinary lateral incision failed, although a considerable part was removed by the crushing action of the forceps. It was then resolved to employ the high operation. The carbolic spray was turned on, and the abdominal cavity opened by means of an incision made over the pubic symphysis, and prolonged upwards for about four inches. The finger was then introduced close behind the symphysis, so that the peritoneum was readily hooked up. An instrument was then introduced into the bladder from the perineal wound, and, pushed forwards by this, it was cut into and the stone extracted. The patient did not long survive. The stone seemed to consist of a large, oval-shaped, uric-acid nucleus, with a very thick external shell of phosphates. Mr. Spence remarked that he had never before been obliged to perform the supra-pubic operation, although he had removed many larger stones. He also drew attention to his mode of cutting down on the symphysis, so as to avoid injuring the peritoneum.

PARIS.

(From our own Correspondent.)

THE death-rate of Paris continues to be very high. This is partly due to the epidemics of typhoid, small-pox, and diphtheria, but mainly to the great mortality amongst children from atresia and infantile diarrhoea, which, from 188 in the week ending July 22nd, reached a total of 228 last week. The *Tribune Médicale* opportunely publishes a paper on the Treatment of Infantile Cholera, by Dr. Boing, which is translated from the *Allgemeine Medicinische Central-Zeitung* of the 26th of June. The results said to have been obtained are so remarkable—fifty recoveries in fifty cases treated—that I do not hesitate to transcribe it for the benefit of your readers. "The method consists chiefly in the use of large quantities of quinine administered in repeated small doses, and in the limitation of food to milk-and-water, which have been previously and separately boiled. At the same time large quantities of wine are given, and sometimes ether." Dr. Boing only comprises in his statistics children under four years of age, and the youngest of these was but two months old. The smallest dose of quinine given in any case was one gramme (about fifteen grains) in the twenty-four hours, of which a proportional part was taken every hour, or half hour. If the dejections are acid, phosphate of lime is also prescribed, and should be used until the urine acquires an alkaline reaction. One little girl three years old, apparently moribund when the treatment was begun, took half a litre (one pint) of Tokay wine in fifteen hours. The French translator states that in some instances, besides the thirty grains of quinine administered by the mouth (in children under four years of age!), as much as 120 grains (eight grammes) were injected into the rectum. Dr. Boing does not appear to have met with any cases requiring more energetic treatment, but should any occur in his practice which resist milder measures, he intends to supplement the administration of quinine by the mouth and bowel by hypodermic injection of corresponding doses of the same alkaloid.

The *Progrès Médical* of last week publishes the first instalment of some lectures by Professor Parrot, upon rickets, which are sure to attract attention. As a cause of this disease, inherited syphilis holds an important place, and one recognised by all writers on the subject; but it has never been considered as the only cause. This, however, is the proposition which the lecturer advances: "All cases of rachitis are derived from one source—hereditary syphilis." As physician to the Hospice des Enfants Assistés, M. Parrot has an unrivalled field for observation; and although the statement is sweeping, it has probably been made upon good foundation. At a recent meeting of the Biological Society Dr. P. Redard exhibited a thermo-electric apparatus, which has been constructed for him by MM. Rumkoff and Gaiffé. It is intended for taking surface temperatures, and records variations of one-fortieth of a degree Centigrade. As an instrument for biological research it will, no doubt, prove most useful, but it is too costly, delicate, and complicated to meet the requirements of a medical practitioner.

A young physician of Lyons, whose name is not given, is said by the *Nouveliste* of that town to be emulating on a small scale the now famous Dr. Tanner. He began to fast on the 1st of August, and will endeavour to remain without food until the 15th. More interested, however, than his American *confrère*, he has staked a hundred louis upon his power of endurance, or rather, that is the sum which is to reward his success.

Although Paris possesses some of the most eminent dentists in the world, the practice of the dental art has hitherto been open to all without any proof of proficiency being required. For some time the members of this branch of surgery have been endeavouring to obtain a law to make it compulsory for every dentist to pass examinations, and obtain diplomas like all other responsible professional men. A dental hospital has recently been inaugurated in the Boulevard Clichy, where theoretical instruction will be given in dental anatomy, physiology, surgery, and therapeutics, and clinical demonstrations on the patients who may apply for relief. It is hoped that the creation of a practical school for study will lead to other reforms.

A commission has been named by the Anthropological Society to take steps to erect a monument to the late Professor Broca. It is formed by MM. Henri Martin, Verneuil, De Quatrefages, Menier, Leguay, Topinard, Parrot, Pozzi, Gavarret, Ploix, and Magitot. Subscriptions may be sent to M. Masson-Leguay, 3, Rue de la Sainte-Chapelle.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, 29th ult., the only petition, so far, in favour of Mr. Dodson's Vaccination Acts Amendment Bill was presented from the Clerkenwell Ratepayers' Association. Petitions against the measure continue to be forwarded, and three were now presented from Swansea Union, vestry of Giles's, Camberwell, and Vestry of St. Leonard's, Shoreditch.—On the motion of Mr. A. Moore a copy was ordered of Dr. MacCabe's recent report on the state of the Belfast Workhouse.

On Friday another petition from the British Medical Association was presented against the Vaccination Acts Amendment Bill.—A return was ordered to be printed of examinations for medical appointments in the East India, army, and naval departments. The thirty-fourth report of the Lunacy Commissioners was laid upon the table.—Mr. Arthur O'Connor gave notice that he would draw attention to the dietary scale in the Dingle Workhouse, and move a resolution.—Mr. Bellingham gave notice that he would ask the Chief Secretary to the Lord Lieutenant of Ireland whether he has any objection to lay upon the table of the House a return of the number of dispensary committees that have availed themselves of an Act passed in August, 1879, giving facilities for providing dispensary houses and dwelling houses for medical officers of dispensary districts in Ireland.

On Monday, petitions against the Vaccination Acts Amendment Bill were presented from Derby Union, Paddington, and St. Pancras, and a petition in its favour was presented from Derby Union. The second reading of the Bill was again deferred, this time to Thursday, but without much chance of its then being reached.—Mr. Parnell asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had received a copy of a report made by Drs. Sigerson and Kenny to the Dublin Mansion House Relief Committee, in reference to the fever in the west of Ireland; and, if so, whether he would lay it upon the table of the House. Mr. Forster replied that the Committee had sent him the report, but as it was not officially obtained he did not see how he could lay it on the table of the House. Fever in the west of Ireland, and especially in the union of Swinford, was declining; so much so, that the medical officer sent down by the Irish Local Government Board was returning to Dublin. To a further question the right honourable gentleman answered that instructions had long since been sent to the boards of guardians in the distressed districts to provide an improved dietary for the suffering poor.—Mr. Hubbard asked the Secretary of State for the Home Department whether, in view of the deficient residential accommodation

for the labouring population within the metropolis, aggravated by the demolition, under Improvement Acts, of unsuitable habitations not hitherto replaced, he would consider and propose some means through which, at the earliest period, a remedy may be applied to an evil so prejudicial to the health and morals of the people. Sir W. Harcourt said the matter was a very serious one, and required a great deal of consideration. Every exertion would be made to carry out the object stated in the question.—Mr. A. Arnold, on behalf of Mr. Macdonald, reverted to the case of poisoning in copper-bronze printing, which was mentioned last week, and asked the Secretary of State for the Home Department if, considering that the boy, William Ball, had suffered severely from an attack of poison prior to the one that he died from, he would direct the attention of the Public Prosecutor to the circumstances of the case, and order a prosecution; and, failing this, if he would bring in a Bill with such provisions as will meet the requirements of similar cases. Sir W. Harcourt said he had communicated with the Chief Inspector of Factories, who was of opinion that copper-bronze printing was not included in the schedule of dangerous trades under the Factory Act, because it did not come under the notice of the Committee who framed the Act. He had instructed the Chief Inspector to inquire what other dangerous trades were unscheduled, and would bring in a Bill next session to remedy the defects of the Act in that respect.—Mr. Middleton asked the Vice President of the Council if his attention had been called to an alarming outbreak of enteric fever which occurred in Glasgow in April of this year. If he was aware that the Medical Officer of Health in his report to the authorities traced the cause of the epidemic to milk supplied from a farm in a neighbouring county. Had the authorities issued regulations under the Order in Council of July, 1879; and, if so, the date. And whether, in view of the repeated outbreaks of fever traced to milk, the Government would take into consideration the propriety of introducing an Act for the sanitary regulation of places of milk-supply to towns.—Mr. Mundella replied that his attention had been called to Dr. Russell's report, that the fever was traced to milk supplied from a farm in Stirlingshire, that the farm was registered and inspected, and that upon receipt of Dr. Russell's report the Stirlingshire authorities prohibited the further selling of milk from the farm, and ordered the water-supply to be amended. At that time some inmates of the farmhouse were suffering from fever, and the water-supply was objectionable. A new water-supply, which was fresh and abundant, had now been obtained, and the inmates of the farmhouse were restored to good health, but it had not yet been deemed prudent to remove the prohibition of the sale of milk. The local authorities applied to had acted with promptitude and intelligence, and he saw no necessity for further legislation.—The following notices were given:—Mr. William Corbet,—To ask the Chief Secretary to the Lord Lieutenant of Ireland if he is aware of the fact that a distinction exists between England and Ireland in regard to the manner of pensioning officers and servants of lunatic asylums on retirement, inasmuch as in England they can receive at the end of fifteen years' service a pension amounting to two-thirds of their salaries, under the Lunacy Acts Amendment Act of 1862, while in Ireland they must have served forty years before they can receive an equal amount; whether he is aware that the clause in the Superannuation Act of 1859, which provides that when professional qualifications are necessary for the holding of any office the Lords of the Treasury may by Warrant direct that in computing the retired allowance of any person so specially qualified a number of years not exceeding twenty be added to the number of years he may have actually served, does not apply to the medical officers of lunatic asylums in Ireland, as their salaries are not paid out of the Consolidated Fund; and whether he will take steps to place the officers and servants of lunatic asylums in Ireland, when incapacitated by age or infirmity to perform their duties, on an equal footing in regard to pensions with their brethren in England. Mr. Sexton,—To ask the Chief Secretary to the Lord Lieutenant of Ireland, whether he has observed that the Rev. P. McNulty, Catholic administrator of the parish of Ballina, informed the Ballina Board of Guardians, at their meeting of the 17th ult. of the existence of thirty cases of fever in one district of the union, and assured the Board that the fever had made its appearance in every case in

families which had been obliged to subsist for a long time on Indian meal, used without milk; that this diet had resulted in dropsy and phthisis, as well as fever, and that a change of diet is necessary if the epidemic is to be abated; whether it appears, from the statement of the Rev. P. McNulty, that the fever had been active in the district in question for a very considerable time; that, nevertheless, its existence there was not known to the Board of Guardians until he informed them of it, and that many of those stricken by fever had neither food, bed clothing, nor any common necessary of life; and, whether, considering the number of districts from which fever has been reported, the danger of a further spread of the epidemic, and the evident inadequacy of the ordinary agencies of the Poor-law system to deal with the present and probable state of things, the Government will specially instruct the Board of Guardians, and will take steps to strengthen the relieving staffs, increase the number of medical officers, and appoint competent nurses to attend upon the sick in localities where such assistance may be needful.—Mr. O'Connor Power (on going into Committee of Supply), to call attention to the Reports of Dr. Nixon and Dr. Woodhouse, presented to the Irish Local Government Board, and to the Reports of Dr. Sigerson, Dr. Kenny, and Mr. J. A. Fox, presented to the Dublin Mansion House Relief Committee, on the condition of the fever-stricken districts of Mayo and other parts of the west of Ireland; and to move: That, in the opinion of this House, the present condition of the agricultural population in Mayo, Sligo, and other parts of the west of Ireland demands the serious and immediate attention of Her Majesty's Government; that effective sanitary arrangements should be carried out in those districts under the authority of the Local Government Board; that it is essential, with a view to preventing the spread of contagious disease, that a change of nutritious food should be given to all persons receiving relief under the Poor-law, or under the system substituted for the Poor-law in certain localities, and that a competent medical staff should be organised without delay, and distributed over those parts of the country visited by fever.

On Tuesday, Lord Hartington read the latest telegrams on the disaster in Afghanistan, from which it appeared that Surgeon-Major Preston was amongst the wounded. The report of the Select Committee on the London Water Supply was brought up, and ordered to be printed.—The following notices were given:—Mr. Mackintosh,—To ask the Secretary of State for the Home Department, whether, as indicated in Her Majesty's Speech, the Lunacy Laws do not require amendment; whether it is the intention of Government to introduce a measure next session for amending these Laws; and whether the Government will, during the recess, institute a full and searching inquiry into the system and working of these Laws by a Royal Commission or otherwise, in order that, with the view of satisfactory legislation, the fullest possible information on the subject may be before Parliament.—Mr. Robert Fowler,—To ask the Under Secretary of State for Foreign Affairs, whether Her Majesty's Government have taken any steps to put an end to the interference, on the part of the Japanese Government, in the drug and chemical trades, which was the subject of a memorial, signed by several influential firms, to Lord Salisbury in August last.

On Wednesday Mr. Corbet postponed his question with regard to officers of lunatic asylums in Ireland until Monday.

On Thursday, Mr. Foster replied to Mr. Sexton that from the report of the medical officer of the Ballina District, it appears that there were under treatment only four cases of simple fever, two cases of rheumatic fever, and one family was convalescent after typhoid. The Local Government Board were very successful in checking the spread of disease, and he had not heard that the present system was inadequate; but, if necessary, the Local Government Board would issue orders to Boards of Guardians to strengthen their staffs. In answer to Mr. Mackintosh, Sir William Harcourt remarked that there was some ambiguity in the Hon. Member's question. With regard to the amendment of the Lunacy Laws, there had been two great speeches from the Throne this year, and this matter was not mentioned in the last speech. He could only say that he had no doubt that the Lunacy Laws did require amendment, but he could not state that a measure would be introduced next session. As to instituting inquiries during the recess, he thought that there was ample material already at

hand for legislation, if it were desired to legislate. Mr. Foster replied to Mr. Bellingham, that it was Boards of Guardians, and not the dispensary committees, who availed themselves of the Act of 1879. He would be happy to grant a return of the boards who had done so. Mr. Pugh gave the following notice for Monday next :—
 "To ask the Secretary of State for India whether the orders of the Governor-General of India, No. 13 of Jan. 3rd, 1880, Military Department, and No. 150 of March 13th, 1880, Home Department, do not contravene the provisions of Section 56 of the Stat. 21 and 22 Vict. c. 106, in that they alter the terms of service and the title to pay, pensions, allowances, privileges, and advantages as regards promotion of those officers; and whether such orders are not so far illegal and void; what redress it is proposed to grant to such officers of the Indian Medical Service as have already been prejudicially affected by the operation of these orders; and what steps it is proposed to take to prevent their further operation?"

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentleman was admitted a Fellow of the College on July 29th :—

Fox, Cornelius Benjamin, M.D. Edin., Ilfracombe.

On the same day the following gentlemen were admitted Members of the College :—

Biss, Cecil Yates, M.B. Camb., Sydenham-park.
 Colquhoun, Daniel, M.B. Lond., Denmark-hill.
 Gabbett, Henry Singer, M.B. Dub., Upper Bedford-place.
 Horrocks, Peter, M.D. Lond., Merrick-square.
 Ludwig, Gustav Heinrich Wilhelm Rudolph, M.D. Leipsic, German Hospital.
 Maclean, Lachlan Hector J., M.D. Heidelb., Bernard-st.

The following gentlemen were at the same time admitted Licentiates of the College :—

Acland, Theodore Dyke, Vincent-square.
 Adam, Caleb Denovan, London Fever Hospital.
 Atkin, Charles, Sheffield.
 Capon, Herbert James, M.D. Brussels, Edgware-road.
 Cree, William Edward, Pemberton Villas.
 Davies, Morgan, M.B. Aberd., London Hospital.
 Dingley, Allen, Argyle-square.
 English, Thomas Johnston, Fulham-road.
 Faithfull, Robert Lionel, M.D. New York, Gower-street.
 Falla, Walter, Jersey.
 Hamerton, George Albert, Lambeth Infirmary.
 Hanson, John Edward, Reedworth-street.
 Hudson, Theodore Joseph, Pyrland-road.
 Lawford, John Bowring, M.D. McGill, Palace-road.
 Perkins, George Chapman Steele, Guy's Hospital.
 Pilkington, Francis Sergeant, Merrick-square.
 Porritt, Norman, General Infirmary, Leeds.
 Richardson, Charles Boards, Great Hadham.
 Ross, James Fredk. Wm., M.B. Toronto, Oxford-terrace.
 Routh, Amand Jules McConnell, Montagu-square.
 Sanders, John William, M.D. Brussels, Guy's Hospital.
 Stansby, Charles John, Hoxton-street.
 Sutcliffe, John, Denmark-hill.
 Ware, John William Langston, Barnstable.
 Warren, Henry Guy Seymour, Cambridge-street.
 Wigg, Alfred Edgar, M.D. Brussels, Albert-street.
 Wilson, John, St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 29th ult. :—

Ackery, John, Queen Anne-street.
 Baddeley, Charles Edward, L.S.A., Newport, Salop.
 Buxton, Thomas, Fazeley, Staffordshire.
 Colledge, Lesley Robert, Surbiton.
 Collingwood, David, Liverpool.
 Cook, Jonathan Neild, Rochdale.
 Marlow, Frank William, Wantage.
 Shearman, Percy Edward, Wimbledon.
 Smith, William Alexander, Clifton, near Bristol.
 Stevenson, Henry Wickham, L.S.A., Castletown, Isle of Man.
 Turton, James, L.S.A., Portsmouth.
 Wood, Arthur George, Trinity-square.

The following gentlemen were admitted Members on the 30th ult. :—

Brookes, Frederick William, Westminster-bridge-road.
 Bullar, John Follett, Southampton.
 Elliott, Nicholas Phillips, St. George's-road.
 Evans, Arthur Owen, Oswestry.
 Greensill, James Haynes, Great Whitley.
 Hart, Alfred Paul, L.R.C.P. Edin., Norwich.
 Henry, George McWilliams, Omagh, co. Tyrone.
 Hunt, James Sidney, Besley, Gloucestershire.
 Maudsley, Henry, Settle, Yorkshire.

Of the 241 candidates examined during the past fortnight,

134 passed to the satisfaction of the Court, and obtained their diplomas; 14 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 93 failed to reach the required standard, and were referred for six months' further professional study. Nine candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical degree or licence recognised by the College, were also admitted Members. With this meeting the Professional Examinations were brought to a close, until November next. The Museum and Library will be closed as usual during the month of September for the necessary repairs, painting, cleaning, &c.

The next Preliminary Examination for the diplomas of Member and Fellow of the Royal College of Surgeons will be held on Tuesday, Wednesday, and Thursday, Sept. 7th, 8th, and 9th, at the University of London, Burlington-gardens. Candidates going in for this examination are reminded that their forms of admission, properly filled up, must be forwarded to the Secretary of the Royal College of Surgeons, Lincoln's-inn-fields, on or before the 17th inst.

UNIVERSITY OF LONDON.—The following candidates have passed the recent Preliminary Scientific (M.B.) Examination :—

FIRST DIVISION.

Aikin, William Arthur, Guy's Hospital.
 Alcock, Samuel King, High School, Newcastle-on-Tyne.
 *Allen, Henry. (Private study.)
 *Anderson, George Elliott Caldwell, South African College and Guy's Hospital.
 Andrews, Charles, University College.
 *Barratt, John Ogilethorpe Wakelin, University College.
 *Bowes, William Henry, Epsom College.
 Bowman, Henry Claxton, Owens College.
 Brock, James Harry Ernest, University College.
 Carr, John Walter, University College.
 Cave, Edward John, St. Bartholomew's Hospital.
 *Chapman, Harry Cecil, St. Bartholomew's Hospital and Royal School of Mines.
 Child, Herbert, Yorkshire College, Leeds.
 Dunn, Louis Albert, Guy's Hospital.
 *Edmunds, Percy James, University College.
 Flemming, Percy, University College.
 Fowler, Alfred Henderson, Guy's Hospital.
 Glover, John Philip, St. Thomas's Hospital.
 Guy, William, University of Edinburgh.
 Halstead, George Ezra, B.A., Guy's Hospital.
 Hart, Herbert Wheatley, Westminster and Guy's Hospitals and Birkbeck Institute.
 *Hurst, Walter, Owens College.
 Innes, Charles Barclay, University College.
 Jones, Frederick Wm. Caton, St. Bartholomew's Hospital.
 Jones, Hugh Edward, Guy's Hospital.
 Jones, Samuel Cromwell, University College.
 Lyndon, Arnold, St. Bartholomew's Hospital.
 Marriott, John, Charing-cross Hospital.
 Mathews, Frank Edward, Owens College.
 Mumby, Langton Philip, St. Thomas's Hospital.
 *Ransom, William Bramwell, University College.
 Robinson, Henry Betham, St. Thomas's Hospital.
 Shipley, Arthur Everitt, St. Bartholomew's Hospital.
 Thane, Edgar Herbert, University College.
 Thomas, Benjamin Wilfred, Charing-cross Hospital.
 Watson, William Ivens Buswell, Guy's Hospital.
 Wells, George Lee, Yorkshire College, Leeds.
 Williams, Reginald Muzio, St. Thomas's Hospital.
 Williamson, Richard Thomas, Owens College.

SECOND DIVISION.

Adami, John, George, Owens College.
 *Adie, Joseph Rosamond, University College.
 *Andrews, Edward Collingwood, University College.
 Arkle, Charles Joseph, University College.
 Bailey, William Henry, St. Bartholomew's Hospital.
 Barnett, Lawrence, University College.
 *Biden, Charles Walter, Charing-cross Hospital.
 Black, Robert, London Hospital.
 Bohrsman, Matt. Chn. R., B.A. Syd., University College.
 Bown, Arthur Thomas, St. George's Hospital.
 Buckmaster, George Alfred, St. George's Hospital.
 Bullock, Thomas Warren, St. Thomas's Hospital.
 Calvert, James, St. Bartholomew's Hospital.
 Carpenter, George Alfred, St. Thomas's Hospital.
 Castle, Bernard, St. Bartholomew's Hospital.
 *Childe, Letterstedt Frederick, Guy's Hospital.
 Cocking, William Tusting, University College.
 Crowther, Fredk. Wm., University College and private study.
 Downing, Charles, St. Bartholomew's Hospital.
 Draper, William Grey, Owens College.
 Earle, Walter George, University College.
 Fisher, Henry Holdrich, Epsom College.
 Frames, Alfred Cronwell, St. Bartholomew's Hospital.
 France, James Mead, Guy's Hospital.
 Francis, Alfred George, University College.
 Freeland, Freeland John, King's College.
 *Gow, William John, Owens College.
 *Grant, William Francis, University of Edinburgh.
 *Griffiths, William, University and Regent's-park Colleges.
 Habershon, Samuel Herbert, Trinity College, Cambridge.
 Hart-Smith, Franke Chamberlain, University College.
 Helme, Thomas Arthur, University College and University of Edinburgh.

Kauffmann, Otto Jackson, Owens College.
 Larkin, Frederick Charles, Liverpool School of Medicine.
 Lawson, Robert, St. Thomas's Hospital.
 *Leach, Priestley, Owens College.
 Macartney, Edward Kendrick, University College.
 M'Cabe, William Alexander Bowes, University College and Victoria College, Jersey.
 Melson, George Hyde. (Private tuition.)
 Meyer, Charles Hartvig Lomo, Guy's Hospital.
 Moss, Arthur James, Owens College.
 *Mukerji, Phani Bhushan, University College.
 Muspratt, Charles Drummond, Guy's Hospital.
 Napier, Francis Horatio, St. Bartholomew's Hospital.
 O'Connor, Edward Kersey, University College.
 Parker, Herbert, St. Bartholomew's Hospital.
 Pearson, James, University College.
 Pereira, Conrad, University College.
 *Perez, George Victor, University College.
 Pollard, George Richard M'Intosh, Guy's Hospital.
 Purnell, Purnell, Guy's Hospital.
 Roome, Stanley Molesworth, Epsom College.
 Shillito, Henry, Queen's College, Birmingham.
 Spencer, Walter Baldwin, Old Trafford School, and Owens College.
 *Stevenson, George, St. Bartholomew's Hospital.
 Storrar, William Morrison, University of Edinburgh.
 Taylor, Charles Henry, King's College.
 Taylor, Joseph, University College.
 Turner, Philip Dymock, University College.
 Vince, John Foster, Queen's College, Birmingham.
 Voelcker, Arthur Francis, University College.
 Walsh, John Henry Tull, Westminster Hospital.
 *Warrick, Frederic Walmsley. (Private study.)
 Weighell, Christopher William, University College.
 Williams, Patrick Watson, University College, Bristol, and private study.
 Williams-Freeman, John Peere, University College.

* These candidates have also passed in the Mathematics of the First B.Sc. Examination, and are now admissible to the Second B.Sc. Examination.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on July 29th:—

Addison, Charles James, Weymouth.
 Crosse, William Henry, Guy's Hospital.
 Farmer, Ernest William White, University College.
 Maxwell, Charles Mayne, Euston-road.
 M'Alister, Donald, St. Bartholomew's Hospital.
 Rhodes, James Havelock Alexander, Osmond-street.
 Rigby, John, Preston.

The following gentlemen also on the same day passed their Primary Professional Examination:—

George Adkins and John Sinclair, London Hospital; Francis Henry Furnival, St. Thomas's Hospital; Michael John Verdon, King's College.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following gentlemen have passed the First and Second Professional Examinations respectively for the double qualification granted conjointly by these two bodies, at the quarterly examination held in July:—

FIRST EXAMINATION.

Crean, William.	Gemmel, Archibald B.
Corkery, W.	Hannah, Frederick R.
Dawson, J. M.	Maidment, F. G.
Dunkin, Charles.	

SECOND EXAMINATION.

Boyd, James D., M.B. Glasgow.
 Fergusson, James H., Londonderry.
 Jackson, William, Glasgow.
 Love, John, Glasgow.
 Macdonald, John, Glasgow.
 Pickworth, Alfred J., Liverpool.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following gentlemen have passed the First and Second Examinations respectively:—

FIRST EXAMINATION.

Bluett, P. E. W.	Dickson, Peter S.
Beatty, W. J.	Partridge, W. S.
Brownlow, Ed.	Taylor, Alfred.
Cameron, Angus.	

SECOND EXAMINATION.

Reheim-Schwarzbach, B., M.D. Würzburg.
 Chalmers, Alexander, Glasgow.
 Erson, W. R., L.S.A., Huddersfield.
 Kelly, M. F., L.A.H., Felling.
 Luddell, J. L., L.S.A. London.
 Macmillan, Colin, Glasgow.
 Macdonald, William, Glasgow.
 Phillips, W., B.A., Portarlington.
 Tinsley, Seth, Malton, Yorkshire.

THE will of Dr. Alfred Swaine Taylor has been proved under £60,000.

MR. A. J. NUNN, late District Medical Officer of the Alderbury Union, has been granted a superannuation allowance of £20 a year.

A CENTRE for the St. John Ambulance Association has been formed at Halifax, and classes are being organised to impart instruction in the first treatment of injured persons. Dr. Britton is the secretary of the new centre.

THE sum of £1800 is stated to have been received as the result of the bazaar lately held for the benefit of the Essex and Colchester Hospital. After the incidental expenses have been defrayed it is expected there will be a surplus to be handed over to the treasurer of the hospital sufficient to reduce the debt due in respect of the recent improvements in the building to about £900.

DR. DAVIDSON, of Banbridge Union, has been refused a retiring allowance of two-thirds of his salary as late medical officer of Crossgar Dispensary, although he had served in that position for the past forty years. We regret that the Banbridge Guardians should have acted in the way they have done to a gentleman who has always efficiently discharged the duties of his office, and who is obliged to retire in consequence of declining health.

WIGAN INFIRMARY.—By permission of the Corporation a gala was held in the Park on Monday, in aid of the funds of the above infirmary.

PRESENTATION.—A handsomely illuminated address and solid silver salver, with a pair of goblets, were presented to Alexander Flood, Esq., who lately resigned the Holywell Dispensary District in the Enniskillen Union, of which he was medical officer for thirty-four years. The presentation was made on Thursday, the 29th ult., by a large deputation, headed by James Bracken, J. P., and Rev. Dr. Clarke, who were chairman and secretary respectively of the Presentation Committee.

YOUGHAL WATER-SUPPLY.—The Town Commissioners having resolved to abandon the waterworks scheme, the Local Government Board for Ireland have requested them to obtain from the medical officer of health a special report as to the sufficiency and wholesomeness or otherwise of the existing water-supply in the urban district. The Board further ask if the pump in Friar-street, which had been condemned as being impure and unfit for dietetic purposes, is still used by the people of that district. A committee has been appointed to obtain samples of the water for analysis.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—There was a good attendance at the annual meeting of this Association held on the 30th July at the Royal College of Physicians, under the presidency of Mr. Mould of Cheadle. At the morning sitting a hearty vote of thanks was accorded to Dr. Lush, the retiring President, and the usual routine business was transacted. In the afternoon the President read a carefully-prepared and exhaustive address, introducing, among other topics for discussion, the question of providing detached villa-residences for lunatics apart from the asylum proper; and Dr. Boyd read a paper upon the simplification of admission formalities. The members dined together in the evening at Willis's Rooms, when they were joined by the Earl of Shaftesbury, Mr. J. T. Hibbert, M.P., and other distinguished guests. Lord Shaftesbury's health having been enthusiastically drunk, his lordship, in feeling terms, expressed the great pleasure it gave him to meet a body of medical and scientific gentlemen, of whose services he could speak with the greatest gratitude. Referring to the length of time during which he had been connected with lunacy work, he favourably contrasted the present state of things both in public and private asylums with that in former years, and alluded to the conscientious manner in which medical practitioners had discharged the duties imposed upon them by the Lunacy Acts, as proved by the evidence adduced before the Parliamentary Committee. The present tendency (one to be guarded against in the public interest) was to let out everybody who was shut up, and henceforward to shut up nobody at all. It was to be hoped that, when measures of lunacy reform were decided upon, nothing would be done which would throw unnecessary impediments in the way of early treatment by a mistaken delicacy in regard to the "liberty of the subject." The two great principles to be maintained were a thoroughly efficient, permanent, and independent body of visitors, and every facility, under proper control, for early treatment. The toast of the House of Commons was responded to by Mr. Hibbert, M.P.

CHARING-CROSS HOSPITAL.—At the recent Distribution of Prizes Lord Watson, late Lord Advocate and M.P. for the Universities of Glasgow and Aberdeen, presided, and after the distribution addressed the company in a felicitous speech, which showed his high appreciation of the profession of Medicine. The following is a list of the prizemen, &c.:—Llewellyn Scholarship, Charles Rout. Gilding Scholarship, W. B. C. Treasure. Governor's Clinical Gold Medal, C. W. G. Burrows. The Pereira Prize, C. R. Lyster. Senior Anatomy, D. L. Jones, silver medal; W. Tibbles, W. B. C. Treasure, J. L. Rodwell, J. Donald, certificates. Junior Anatomy, W. H. Haw, bronze medal; E. S. Josling, B. W. Thomas, A. F. Turner, certificates. Senior Physiology, J. T. Tibbles, silver medal; J. Donald, W. B. C. Treasure, D. Llewellyn Jones, W. Tibbles, certificates. Junior Physiology, H. d'Arcy Power, bronze medal; E. S. Josling, E. Berkley, certificates. Chemistry, B. W. Thomas, silver medal; J. Marriott, A. E. Nelham, R. S. Oram, certificates. Senior Medicine, Charles Rout, E. E. Newnham, silver medals; C. W. G. Burrows, A. Honman, certificates. Junior Medicine, H. R. Hancock, bronze medal; J. Donald, W. C. Beatley, J. H. Taylor, certificates. Senior Surgery, Edwin Wooton, silver medal; C. W. G. Burrows, Charles Rout, certificates. Junior Surgery, J. Donald, bronze medal; G. Locke, certificate. Botany, S. Wyborn, silver medal; J. Donald, W. B. C. Treasure, certificates. Materia Medica, G. Locke, silver medal; H. R. Hancock, W. B. C. Treasure, certificates. Midwifery, Charles Rout, silver medal; A. Honman, certificate. Forensic Medicine, C. W. G. Burrows, silver medal; W. J. Haddock, certificate. Pathology, A. Honman, silver medal, W. Niblett, certificate. Practical Chemistry, W. C. Beatley, Silver medal.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. James Macgregor Mackay, of Brighton, bequeathed £1000 to the Edinburgh Royal Infirmary. Miss Jessie Gordon bequeathed £1000 to the Paisley Infirmary and Dispensary. Mr. John Cuttell, of Long Walls, has given £1000 to the Huddersfield Infirmary. Mr. R. Barnard, of Painswick, bequeathed £200 each to the Stroud Hospital, the Bristol Infirmary, the Gloucester Infirmary, and the Bristol General Hospital, and £100 each to the Hospital for Incurables at Putney and the Asylum for Idiots at Earlswood. The Worcester Infirmary has become entitled to £100 under the will of Dr. Nash. Lady Codrington has given £50 to the Victoria Hospital for Sick Children. The Mercers' Company have given thirty guineas to the West-end Hospital for Paralysis and Epilepsy. Mrs. Ann Cash, of Hackney-road, bequeathed £300 each to the Central London Ophthalmic Hospital, the German Hospital, the North-Eastern Hospital for Sick Children, the London Hospital, and the Metropolitan Free Hospital, and £100 to the Royal Hospital for Incurables. "The Misses B." have given one hundred guineas to the building fund of the North London Hospital for Consumption, and three hundred and fifty guineas to name and endow a bed. The Charing-cross Hospital has received £105 from the Mercers' Company, and £100 from the Goldsmiths' Company. The Trustees of the residuary estate of the late Sir George Bowles have assigned £2000 to the Shepton Mallet District Hospital.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BENHAM, F. L., M.B., has been appointed Resident Clinical Assistant to the West Riding Asylum, Wakefield.
BRYDEN, R. J., M.R.C.S.E., L.S.A.L., has been appointed Physician's Assistant to the Bristol General Hospital, vice E. W. Hope, M.B., resigned.
GEOGHEGAN, E. G., M.D., has been appointed Assistant Medical Officer to Portsmouth Borough Asylum, vice Hay, resigned.
GEORGE, G. A., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Dorchester District and the Workhouse of the Dorchester Union, vice Emson, resigned.
GOYDER, C. M., M.B.C.S.E., L.R.C.P.L., has been appointed Senior House-Surgeon to the Newcastle-on-Tyne Infirmary, vice J. D. Dixon, M.D., resigned.
HEATON, C. W., F.C.S., has been reappointed Public Analyst for the Parish of St. Martin-in-the-Fields, for one year. £50 per annum and fees.
HOPKINS, J. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Eccleshall District of the Stone Union.

HORNE, A. J., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Assistant-Physician to the Rotundo Hospital, Dublin.
JONES, T., M.B., F.R.C.S.E., has been appointed Consulting Surgeon to the Children's Hospital, Pendlebury.
KEELAN, P., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Medical Officer to the Callon Dispensary, Ardee Union.
LYTLE, J., M.D., M.Ch., has been appointed Junior House-Surgeon to the Wigan Infirmary, vice J. C. B. Robinson, L.R.C.P. &c., resigned.
MCARDLE, Mr. J. S., has been appointed Resident Surgeon to St. Vincent's Hospital.
MCDONNELL, E. P., L.R.C.S.I., has been appointed Resident Surgeon to Gervis-street Hospital, Dublin.
MANBY, F. E., F.R.C.S.E., has been appointed Honorary Surgeon to the Wolverhampton and Staffordshire Hospital, vice Newham, resigned.
MONTFORT, A. H., M.D., M.Ch., has been appointed Assistant House-Surgeon and Dispenser to the Kent and Canterbury Hospital, vice Mr. T. F. Vaisey, resigned.
NEWHAM, C. A., M.R.C.S.E., L.S.A.L., has been appointed Consulting Surgeon to the Wolverhampton and Staffordshire General Hospital.
O'CONNOR, C. J., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Medical Officer to the Clane Dispensary, Naas Union.
O'DEA, P. St. L., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Ennistymon Dispensary, Ennistymon Union.
RICHARD, B. M., L.F.P.S.G., has been appointed Medical Officer of Health for the Burgh of Dumbarton.
SUTHERLAND, J. F., M.B., has been appointed Surgeon to H.M. Prison, Duke-street, Glasgow, vice Leishman, resigned.
WALSH, J. L., L.R.C.S.I., L.R.C.P.Ed., has been appointed Medical Officer to the Kilmacthomas Dispensary, Kilmacthomas Union.
WILKINS, G. H., M.R.C.S.E., has been appointed Visiting Medical Officer to the St. Michael's District of the South Lambeth, Stockwell, and North Brixton Dispensary.
WRIGHT, G. A., M.B., B.A., F.R.C.S.E., has been appointed Surgeon to the Children's Hospital, Pendlebury, vice Jones, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ARNOTT.—On the 29th ult., the wife of Sandford Arnott, M.R.C.S.E., of a son.
KENNEDY.—On the 3rd ult., at H.M. Penal Settlement, Essequibo, British Guiana, the wife of David Kennedy, M.B. &c., of a son.
LEACHMAN.—On the 27th ult., at Fairley, Petersfield, the wife of A. Warren Leachman, M.D., of a son.
MAY.—On the 28th ult., at Pentonville-road, N., the wife of Edward H. May, Surgeon, of a daughter.
PURDON.—On the 14th ult., at Guernsey, the wife of J. E. Purdon, Esq., M.B., Surgeon-Major, of a daughter.

MARRIAGES.

CHARLES—GORDON.—On the 31st ult., at St. Matthias', Earl's-court, T. Cranstoun Charles, M.D., to Georgiana, daughter of the late Adam A. Gordon, M.A.
FOSTER—WEBB.—On the 27th ult., at St. Barnabas Church, Pimlico, Henry George Foster, Esq., of Attleborough, Norfolk, to Mary Clementina, second daughter of Dr. Edward Lowe Webb, of St. George's-road, Pimlico, S.W.
NEWTON-CLARE—ANScombe.—On the 28th ult., at St. Jude's, Mildmay-park, Edward S. Newton-Clare, M.R.C.S.E., of Calne, Wilts, to Emma Anscombe, niece and adopted daughter of the late Thomas Honychurch, of Mildmay-park.
O'BRIEN—MEREDITH.—At the Church of St. Joseph, Highgate, London, Michael Joseph O'Brien, L.K.Q.C.P.I., to Lizzie Baldwin, third daughter of the late William Meredith, of Derrylough, Queen's County, Ireland.
WALKER—ORIEL.—On the 15th ult., at St. Mary's, West Kensington, by the Rev. J. F. Sergeant, M.A., Vicar, assisted by the Rev. J. Henry Smith, B.A., of Dulwich College, Horace Walker, L.R.C.P.L., M.R.C.S.E., of No. 4, The Cedars, West Kensington, to Maria Louisa, third daughter of the late Dr. Oriel, of Alfred-place, W.C., and of Mrs. Oriel, of Elms House, West Kensington. At home after August 15th.
WORSLEY-BENISON—DAVEY.—On the 29th ult., at Harecourt Congregational Church, Canonbury, by the Rev. W. M. Statham, Henry Worsley Seymour Worsley-Benison, eldest son of the late Henry Worsley-Benison, Esq., of Bristol, to Mary Louisa, second daughter of the late Charles Davey, Esq., of Canonbury.

DEATHS.

GRIERSON.—On the 30th ult., at Towerside, Weston-super-Mare, the residence of her son-in-law, Major-General Hailes, Mary McCulloch, widow of David Grierson, M.D., Deputy Inspector-General of Hospitals, Poona, in her 71st year.
HEELIS.—On the 1st inst., at his residence, Blatchington-road, West Brighton, Sussex, Robert Heelis, M.R.C.S.E. & L.A.C., aged 81.
KENNY.—On the 18th ult., Dr. Randal Y. Kenny, of Killeshandra.
ROBERTSON.—On the 24th ult., at Redland-green, Bristol, H. Robertson, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

FINGERS V. KNIVES AND FORKS.

THE arrangements devised by the authorities presiding over the education of the children of the new Parochial Schools at Bedminster would appear to be distinguished by a charming simplicity, almost indeed of a primitive character. The teaching of the young idea how to shoot seems, at all events, in the opinion of the guardians of the poor children of Bedminster, not to include impartation of the knowledge of the use of the knife and fork. The following is from the *Bristol Mercury*:—"Mr. Richard Harding said that the Visiting Committee had gone through the new schools that morning, and were generally pleased with the arrangements. On visiting the dining apartment, however, they found the children's dinners ready, but beyond a spoon there was nothing for them to eat with. From inquiry he found they had to use their fingers, and he did not think such a thing should continue. There was little use in training them properly and forcing them to eat their food like cannibals. He thought that knives and forks should at once be ordered." We think so too. Either give the knives and forks, or take away the spoons and revert to the "natural" mode of devouring.

Pericula.—Our correspondent's power of recovering for the period in question is very doubtful.

Eucalyptus.—We cannot supply the information required.

Sardinia.—Barnes.

PASSAGE OF A FISH-BONE FROM MOUTH TO ANUS WITHOUT CAUSING INJURY.

To the Editor of THE LANCET.

SIR,—Last night (August 3rd) a carman in the employ of one of the great Railway companies applied to me for advice with regard to a swelling about the anus. He had only noticed it during the day, and it had given him great pain during defecation and while sitting on his box. On my seeing him a little after 8 P.M., and hearing his story, my first thought was that he had an inflamed pile, and I asked him to let me see the swelling. On looking I could see nothing but some pieces of skin about the anus (condylomata), and nothing to give rise to his symptoms. I then touched these, and in one of them, where he felt the most pain, I felt a hard, sharp substance, giving me the idea that I had to deal with a needle. On using gentle traction upon the point which protruded, I was able to bring away a fish-bone (apparently from a haddock), about an inch or rather more in length, with complete relief of all symptoms.

The patient's history is this: On July 31st (i.e., three days before) he had eaten haddock for supper, and no fish since. This bone then must have passed from mouth to anus, and, fortunately for him, without causing perforation. The case is worth recording, as showing how necessary it is always to examine every case of piles coming before a medical man.

I am, Sir, yours &c.,

Fore-street, E.C.

LUNATICS IN IRISH WORKHOUSES.

At the close of last year, 3491 lunatics were located in 163 unions throughout Ireland, of which number 1382 were males and 2109 females, being 154 in excess of the previous year. A distinct and progressive contrast is noticeable as regards idiocy; for enumerating, on the one hand, the simply idiotic, and the idiotic or imbecile labouring under epilepsy, those under thirty years of age amount only to 560 between both sexes, while those over that age reach 1198. Hence it may be naturally inferred that in the present generation the recurrence of idiocy is on the decline—a fact, no doubt, attributable in great measure to the safe harbouring of the afflicted in early life through the instrumentality of asylums and poorhouses, with a consequent check to its propagation.

SIMULATED (OR SO-CALLED) HYSTERICAL ERUPTIONS OF THE SKIN.

To the Editor of THE LANCET.

SIR,—The following eruptions of the skin we may find more generally imitated—viz., pemphigus, erythema, eczema, dyschromata or discolorations, ulcerations, and sometimes alopecia. Several cases of simulated eruptions having been brought under my notice lately, and more particularly one very forcibly, I deem it worthy to bring them to the notice of the profession, as they may occasionally occur in practice. Hysteria as a term has been applied to these simulated eruptions of the skin, and no doubt hysteria is an imitative disease, and is seen in many and strange forms, as fasting, of which several instances occur to most of our memories. Notwithstanding these simulated eruptions are mostly to be found amongst the female sex, and that hysteria mostly occurs to them about the time of puberty, I do not think we must take all we see for granted as hysterical; indeed I have seen several of these so-called hysterical skin affections very soon pass away when treated firmly and kindly. I have heard of and read of some cases of simulated eruptions seen in males; but I confess I have only seen one, and that a very doubtful case—that of a man, who I firmly believe only came to the hospital to be taken in for his keep, who had patches of ecchymosed skin caused by pinching I had no doubt, and, after being questioned closely, suddenly left the hospital.

The first case was an example of imitated erythema marginatum, and very well copied, too, by a well-nourished young woman, aged twenty-two, about middle height, and sallow complexion. She came under my notice at the hospital on the 22nd of April last, with an eruption on the breasts, shoulders, forehead, and inner side of the ankles, of a bright red colour, scaly, and "very tender to the touch," and accompanied with inflammation. In parts there were seen long scabs, caused by the patient's scratching; eczema even had come out, so great was the irritation set up in the skin. In other parts were seen brownish stains, not unlike old syphilitic stains. The girl's history of the eruption was that at first there came out small patches of redness on the arms, very irritable, and showing some small blisters, gradually spreading, and that she had been under Dr. Broadbent's and Mr. Morris's care at St. Mary's Hospital for three weeks. Not quite understanding the character of the eruption at first, I closely questioned the girl, and desired the matron to watch her very closely, as I strongly suspected the nature of the eruption. After a few days, and at my next visit to the hospital, the matron brought me a small paper-bag, which had contained mustard, and which she had found secreted by her. This made it quite clear how this assumed erythema was caused. I then wrote to Dr. Broadbent, who kindly informed me "that there had been a patient suffering from an anomalous eruption of the skin, which he found to be caused by mustard, but unfortunately she went out of the hospital unexpectedly before he had the opportunity to speak to her. I merely used a little vaseline to the skin, which soon healed it."

The second case was that of a young woman, aged thirty-six, who came to me in August last with an eczematous eruption on both legs, on no other part of the body, the patches nearly symmetrical in size, which she said she had had on and off for some years, and had seen several medical men for it. From the sharply-defined nature of the eruption, and from the fact of the patient asking me to write a certificate to enable her to obtain benefits while she should be laid up, I had my doubts as to the case, and much confusion arose to her on my closely questioning, and her admitting the fact of the self-infliction.

The third case was that of a girl about eighteen, who came to see me with an eruption of well-marked bullae on the anterior surface of both legs, on no other part of the body, quite distinct, closely simulating pemphigus, which I elicited was caused by applying blistering fluid. This patient was certainly subject to hysteria, the menses being regular. But certainly others I have seen could not be put down to hysteria.

Yours truly,

JAMES STARTIN.

Sackville-street, July, 1880.

CURIOUS CASE IN VETERINARY PATHOLOGY.

To the Editor of THE LANCET.

SIR,—I have a greyhound puppy, aged three months, and ever since he could see there is on the ball of each eye at the outer corner a quantity of hair, which entirely covers the white of that part, and approaches quite up to the pupils. I have shown the dog both to a surgeon and veterinary surgeon, and they have never met with a similar case. If any of your readers have, I should be glad to hear as to what treatment was adopted.

I am, Sir, yours &c.,

July, 1880.

COURSER.

MEDICAL ETHICS.

To the Editor of THE LANCET.

SIR,—We hope you will find space in your journal to insert the following correspondence between ourselves and Dr. Davison, which we shall be also glad to learn your opinion and the opinion of the profession generally concerning.

After receiving the first two letters of Dr. Davison's, refusing to release Mrs. S— from her arrangement with him, which release we believed any medical man would at once have given who knew all the facts as Dr. Davison said he did, we again called on Mrs. S—, and said that if she really wished Dr. W. H. Sheehy to attend her as before, he would do so, and would forward the fee (two guineas) to Dr. Davison, as that was the only way by which an arrangement could be made.

We are, Sir, yours truly,

W. H. SHEEHY.

PATMORE SHEEHY.

Claremont-square, N., July 2nd, 1880.

[COPY.]

8, Oxford-terrace, Upper Holloway, N., May 26th, 1880.

SIR,—Mrs. S—, of —, who engaged me some time ago to attend her in her confinement, writes me this morning, asking whether I will release her from her engagement, *because you were good enough to call upon her yesterday, and make her an offer of your services.*

I have refused to release her, as I do not consider her reason for wishing to break our arrangement a valid one, unless on the condition of paying my fee—viz., £2 2s. If under the circumstances you are disposed to hand me that amount, you are at perfect liberty to do the necessary work.

I am, Sir, yours faithfully,

JAS. DAVISON.

Dr. Sheehy.

[COPY.]

4, Claremont-square, N., May 26th, 1880.

DEAR SIR,—I have received your letter concerning Mrs. S—. The facts you do not appear to quite understand.

Mrs. S— has been a patient of mine for many years, and in all her confinements I have attended her. This winter my health has been much affected, so that Mrs. S— believed that I should not be able to attend her as before.

I called on Mrs. S— yesterday, as I promised some time ago, not knowing Mrs. S—'s condition, and not knowing that she had spoken to any medical man about herself. Mrs. S—, on finding that I was able to attend her as before, naturally wished that I should do so.

I am, yours truly,

W. H. SHEEHY.

Dr. Davison.

[COPY.]

May 26th, 1880.

DEAR DR. SHEEHY,—I have written to Mr. Davison, and he does not seem willing to give me up. He does not think it fair, so we must let the arrangement remain. No doubt you will hear from him.

Trusting it will not make any difference in the future,

From yours very truly,

L. S—.

[COPY.]

8, Oxford-terrace, Upper Holloway, N., May 28th, 1880.

SIR,—I am in receipt of your letter of the 26th inst., in reply to mine respecting Mrs. S—. Pardon me, but your letter is most unsatisfactory to me. You are in error in supposing I did not know all the facts. I knew all you mention in your letter, and something more.

The fact of Mrs. S— having duly engaged me should have been in itself sufficient to have prevented you putting pressure on her to get out of her distinct engagement. In commercial life your conduct would be much reprobated, and in our profession I think such behaviour cannot be too severely condemned.

Your letter does not deal with my proposition to you, and I shall therefore assume that you are not so desirous of attending Mrs. S— that you will feel disposed to do so without fee.

Take my advice—viz., leave touting to tradesmen, and in doing so you will earn for yourself and your profession respect.

I am, Sir, yours faithfully,

JAS. DAVISON.

Dr. Sheehy.

[COPY.]

4, Claremont-square, N., June 3rd, 1880.

SIR,—My father attended Mrs. S— this afternoon for the seventh time. He forwards a cheque for two guineas, as demanded in your ungentlemanly and unprofessional letters. An acknowledgment of it he requests.

I am yours truly,

PATMORE SHEEHY.

Dr. J. Davison.

[COPY.]

8, Oxford-terrace, N., June 4th, 1880.

SIR,—I am in receipt of cheque for two guineas (Mrs. S—'s fee), for which I thank you. I quite expected the cad's cry of "ungentlemanly" and "unprofessional." Our mutual agreement in these points is remarkable, with this difference, that it never occurred to me to suspect your father of being a gentleman.

Mr. P. Sheehy.

I am, Sir, yours truly,

JAS. DAVISON.

Dr. Davison's Explanation of Correspondence between Dr. Davison and Dr. Sheehy.

Last February I received a message to call and see a Mrs. S—, who was desirous of engaging me to attend her in her confinement. I called in the course of the day, and Mrs. S— duly engaged me to attend her in June. Mrs. S— explained that she had been previously attended by Dr. Sheehy, but now wished to change her medical attendant, because she considered it too far to send to Pentonville for Mr. Sheehy, now that

she had moved her residence to Upper Holloway. Besides, she added she was sorry to say Dr. Sheehy's eyesight was very bad, and she was afraid to trust him. Having only recently come into this neighbourhood, she had also to change her nurse, and I took some pains to secure her a good one. So far all was satisfactory, and I confess I was rather surprised to receive a note by hand of a relative of Mrs. S— a few days before her confinement, asking whether I would release her from her engagement, because, as her note says, "Dr. Sheehy had called upon her, and offered her his services." The relative who brought the note stated that Dr. Sheehy's visit and offer had quite upset Mrs. S—. I at once declined to release her from her engagement, as I did not consider Dr. Sheehy's offer quite a correct proceeding, nor a valid reason why I should give up an engagement I was prepared to carry out. Mrs. S— the same day sent me a second note, which I here copy:—

"DEAR DOCTOR,—I should be very sorry to have any unpleasantness, so will let our arrangement remain. Hoping to see you soon."

I wrote Mr. Sheehy at once, telling him of my refusal to give up my engagement unless on payment of my fee. His reply was evasive, and I was informed by the nurse that it was his intention to attend the case, and simply ignore my engagement. I wrote him again in language no one could mistake, the reply to which was an insulting note from his son, telling me his father had attended Mrs. S—, and enclosing cheque for my fee. I retorted, and expressed the contempt I felt for any professional man who could so demean himself.

* * We publish the correspondence sent to us by Mr. Sheehy, with the consent of Dr. Davison, in letters which show us that he thinks he is right. We do so with some regret, feeling that neither party will think he has done his best in respect of the amenities either of letter-writing or of the profession, but from a sense of necessity, feeling the difficulty of placing the controversy more concisely, even if at all, before our readers, without also giving the correspondence. In truth, in most of these cases the correspondence is the controversy. About the abstract merits of such a case as this, ninety-nine men out of a hundred would not differ. They would concede the right of an old practitioner who had attended a lady with seven children, and was overtaken with a great physical calamity, to call on his patient and represent to her that he was still capable of attending her in her eighth confinement, if her wish seemed in that direction, and if an engagement with another practitioner, made in the belief that her old adviser was incapacitated, could be set aside. If ever one practitioner is entitled to the kind consideration of another, it is when he is overtaken by an illness which must ultimately disable him, but which has not yet quite done so. With the love of work surviving the loss of eyesight, and perhaps a son with good eyes to help, it would be hard to prohibit an old accoucheur from attending an old patient, or blame him for representing that he was able to do so, especially if he acted without knowing that other arrangements had been made. But, still, there are rights on the other side. Dr. Davison had been four months retained, and in this capacity had taken some trouble, and perhaps had come under some inconvenient restraint with respect to the obstetric engagement. He was fully and legally engaged, so much so that he might have claimed his fee had the patient had no further communication with him. We will go further, and say that Mr. Sheehy would have done better than he did, after receiving the letter of Mrs. S—, dated the 26th May, to have let the case remain in Dr. Davison's hands. But there is another party in this controversy—the patient,—and, as in most professional controversies, she has something to answer for. If only medical men would take each other's account direct, and not trust to the literal report of the patient, who often quite unintentionally errs, much less harm would be done. The patient here was evidently in a strait. She wished for her old doctor, and she also wished for a nearer one. Her action at the time of her need must be held to show which way her mind inclined. She sent for Mr. Sheehy, and this accords with Mr. Sheehy's important statement, "On finding that I was able to attend her as before, Mrs. S— naturally wished that I should do so." The patient, in her message to Dr. Davison, made too much of Mr. Sheehy's "offer," and too little of her own wish. But the wish of the patient and the whole circumstances of Mr. Sheehy being as they were, there should have been no difficulty in adjusting the matter with Dr. Davison. There are moments for the most generous judgment possible of our fellows, and one of these moments certainly occurs when he is overtaken with a great affliction. We now come to the correspondence, and we shall not dwell upon that. If our judgment be right, there is no excuse for the expressions used and the advice tendered by Dr. Davison in his letter of the 26th of May to his senior by many years, and which not unnaturally led to further expressions on both sides, which discredit the profession and deface the letters, and which we venture to say will be regretted in cooler and more benevolent moments.—ED. L.

THE Secretary of the Medico-Ethical Association of Manchester is thanked for the fifth edition of the Rules of the Association.

C. T. C.—It is sufficient.

D. Ingle.—The paper is marked for insertion.

COMPULSORY MEDICAL EXAMINATIONS.

THE *Athenæum* states that "the authorities of Guy's Hospital Medical School have resolved upon making an idle first year's student a rare thing, if the help of a compulsory and non-competitive examination is sufficient for that purpose. This examination has just been held for the first time, and students have had four elementary papers on the principal subjects of their first year's lectures. The progress of our great hospitals into fully organised Medical Colleges is thus proceeding without hindrance; but a conjoint examination for diplomas is as far off as ever."

Dens Sapientie.—It has been computed that there are 13,000 dentists in the United States.

Mr. H. J. Rutherford.—The error was inadvertent.

P. H. D.—Yes.

THE NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.
